ADEQUATE MEDICAL SERVICE OF THE FUTURE*

OTTO P. GEIER, M.D.
CINCINNATI

In the strikingly evolutionary programs of the twentieth century, no group of individuals is about to have its old-time relationships more radically changed than the group of physicians. Many factors, social and economic, will be responsible. Some of these most evolutionary changes will promptly and voluntarily come from within the profession; others will be forced on the profession. It is evident that we have for all time passed beyond the stage of the absolutely individual and personal relationship of family physician and patient, to one in which the community steps in to safeguard itself against any abuse of this circumscribed relationship, and demands collective action in matters of health for the benefit of all.

SOCIAL AND ECONOMIC PROBLEMS

The concentration of population in cities has developed problems beyond the control of the private physician. In the trail of density of population have come the tenement, sweat-shop, bad housing and living conditions, tuberculosis, alcoholism, venereal disease, poverty, delinquency and crime. The development of industry with its occupational hazards has created another series of health impairments which the family physician may have the knowledge to alleviate, but the prevention of which is entirely beyond his control. The establishment of the public health department was a partial answer to these new social requirements.

The coming of industrial concentration presented other social disorders. We have witnessed the development of class feeling and the estrangement between labor and capital. Strikes and lockouts were only a consequence. The valued relationship of master and man passed out. They no longer had real personality for each other, no longer worked side by side, they lived further apart, thus making the difference in their scale of living more evident. The gulf between poverty and riches was widened. Unemployment, seasonal employment, the physically unfit, the unemploy- [illegible] industrial hobo, the labor turnover, all huge size as medical and social problems of such Society to spell defeat of their solution.

are largely realizing that the problems of industry the communit problems; that the major portion of is engaged in industry and that when badly administered, it is therefore a menace to the peace, health and happiness of the whole community. When properly administered, it is of inestimable value socially and economically. Whatever industry does, because of its size, is impressive.

Has the medical profession kept pace with society in its realization for the necessity of community thinking, community action? Has the profession recognized that its work is fundamental to the solution of every social problem thus far presented? Are we thinking in terms of the mass, and adjusting our work to the new social needs? Have we fully realized our obligations, our opportunities? Do we actually sense the full meaning of the fact that every social disorder has a medical aspect? Do we really appreciate that most social misfortunes are founded in the neglect of the laws that make for a healthy mental and physical state, and that it is our bounden duty to apply ourselves to these tasks? Do we understand that these social disorders call for a new medical order? To the extent that we do understand, we shall be either producers of social reform or merely its by-products. Ours is the choice.

It was with these thoughts in mind that your officers deviated from the usual style of program for the Section on Preventive Medicine and Public Health, and have endeavored to encourage an extended discussion of the social and economic status of the practice of medicine. In thus drawing your attention away from the discussion of detail of administration, away from the refinements of the application of scientific and hygienic measures, I hope to visualize a broad concept of the potentiality of the socially minded physician in private practice, in public health practice, and especially in industrial practice. I am trusting that the discussion may point the way toward a more adequate practice of medicine, the medicine of tomorrow.

Ours is no effort by legislation to thrust revolutionary methods on the members of our profession. It is rather to set out in bold relief some of the rational and evolutionary processes that are taking place, and may yet take place, within the profession; to measure, if possible, their relative social values, and to deduce from this study the direction in which medicine must go to meet the new social order, to produce adequate medical service. I shall confine this discussion to the consideration of three of these well defined tendencies:

1. Higher standards of private practice by refinement in diagnosis and treatment through group practice.
2. Higher standards of public health practice (emphasizing school dispensaries).
3. The development of industrial medicine — the new specialty.

---

* Chairman's add read before the Section on Preventive Medicine and Public Hea at the Sixty-Eighth Annual Session of the American Medical Ass ion, New York, June, 1917.

Scientific attainment will come through the emphasis of the first. The application of this science to the ultimate social good will proceed largely through the latter two. All three together, through years of patient effort, will make for that final goal, adequate medical service.

In contrast to the stated need for years of evolutionary growth, the adequate medical service is being heralded as possible of accomplishment over night, by the mere process of legislative action, changing the method of compensating the physician through a central collecting agency. Some of us are ready to affirm that there is an actual shortage of adequate medical service both quantitatively and qualitatively, and that, therefore, no kind of legislation can make it purchasable by all or for all; that the chief social need is for the development of some organized plan of reform within the profession that will eventually produce and make procurable adequate medical service.

We are deeply indebted to the proponents of social insurance for setting forth the direct relationship between poverty and disease, for emphasizing the economic advantage to society of grappling vigorously with the problem of disease, and for pointing out the shortcomings and the inadequacy of present medical service. The argumentation has crystallized recognition of the immense contribution that scientific preventive medicine should make to the nation's better health. But, in their unfortunate haste to legislate, and in their intolerance of further discussion, they have not taken time to write into their instrument the fundamentals that attack disease and thereby prevent poverty.

It is not my purpose to decry compulsory sickness insurance, but to present a partial program for the socialization of medicine which will be worth while for itself, but which incidentally must finally become the foundation of any rational health insurance plan against which will be found but few opponents.

As the proposed health insurance bill revolutionizes the relationships of the physician, we are by that act immediately threatened with a new future for the practice of medicine. Is it not timely, therefore, that the medical profession should decide what that future shall be?

The subject of adequate medical service is of vital interest to the wage earner, the political economist, the physician, the employer and the public. Ours is an effort through group practice or a symposium discussion to diagnose our social miseries, and then to write a prescription. It is fair to assume that if a program can be devised that will meet the needs of the individual, it can probably be extended advantageously to meet the needs of the community.

What are the individual's social needs?

1. Health, so that he may work effectively and thereby earn a good wage.
2. Employment in an industry free from health and accident hazards.
3. A healthful home accessible to his work.
4. Intelligent medical care in time of illness.
5. Protection to his home and industry.
6. Good schools for his children which safeguard the health.
7. A health department which will protect his family against contagious diseases, and safeguard his food supplies.
8. Healthful recreation for himself and family.

It will be seen at a glance that his success and happiness are predicated on his health and that of his family; that this health is possible only through collective action, and that the family physician appears only when some health agency has failed to prevent disease.

For the reason that most physicians are still individualists and have failed to recognize that health is no longer a personal matter, a discussion of the necessary changes in the practice of medicine is timely.

A conviction has been born out of considerable observation and experience in philanthropic and social work that physicians do not comprehend their direct relation to sociology. The physician should be the leader in community thought in all problems of disease, insanity, crime, delinquency and dependency. To do so, however, he must have a wide angled vision of social disorders.

If disease is so costly, what definite and practical means are now at hand to reduce that loss? How far can we prevent disease? To those who have given only cursory thought to this subject, the annual loss of $500,000,000 charged to illness seems impressive. But let us consider what the great economic and social wastes are that make for sickness and poverty. Let us see whether these wastes are preventable, and if so, should not society rather give its attention to this worthwhile program which, in accomplishment, will be striking at the roots of the evils which to many appear momentarily to justify the medical and social revolution involved in compulsory sickness insurance?

Tuberculosis, it is said, claims an annual economic loss in this country of nearly $500,000,000. Bad housing, bad living, alcoholism, venereal disease, and occupational diseases would surely add an equal number of millions. The excessive annual labor turnover, or the quick hiring and firing of help is responsible for another $500,000,000. Voluntary absence from work due to personal reasons or lack of application causes an annual loss of more than $500,000,000.

Now these social and economic losses, totaling billions, are all preventable if society is really in earnest about improving its fundamental conditions and those of the medical profession. Remove these drains on the wage earner's health and purse, and he will need none of the proffered aid from the state in the guise of compulsory sickness insurance.

We can form some estimate, for instance, of the cost of alcohol and venereal disease to society, if we take the sum total of the cost of prison administration, maintenance of almshouses, institutions for the insane and feebleminded, the cost of caring for delinquent and dependent children, the blind, and the cost of the erection of hospitals, and particularly the care of sickness due to the factors of alcohol and venereal disease.

Alcohol is charged with an increased mortality of
from 25 to 75 per cent. in its users. The morbidity
must follow about the same curve. Will the proposed
model health insurance bill reduce alcoholism [illegible]
venereal disease by one iota? On the o[illegible] towha[illegible]
would not some constructive program lo[illegible] the [illegible]
the reduction of these enormous burde[illegible]iately re[illegible]
munity be the most logical way of imm[illegible] purchasing
ing poverty and thereby furnishing the long last-
power for medical service? Consider the mere pay-
ing financial drain of tuberculosis, take the slightest
ment of two thirds of the wages, from the white
dent in the fearful economic l[illegible] controlled only by
plague? This disease can be fin-

early diagnosis. The early diagnosis and cure of tuberculosis can come only through higher standards of medical practice, medical supervision, physical examinations and reexaminations, through better housing conditions and sanitary measures, and through the reduction of alcoholism and venereal disease on which this plague is so largely engrafted.

SOCIAL IMPROVEMENT THROUGH MEDICAL IMPROVEMENT

What plan for social improvement is worth our time, our discussion, our money? If we, as physicians, would be successful in the improvement of the health and happiness of the nation, we must at the outset reorganize both private health practice and public health practice. Both must be placed on a higher plane of efficiency. Next, we must set up adequate public health machinery by reorganizing the federal, state and municipal health work. This work must be entirely removed from political control, so that scientific attainment and spirit may pervade the whole organization, and then we may have the maximum of coordination and cooperation throughout this machinery for the attainment of 100 per cent. efficiency in working for public health. The proposed health insurance bill affects but 30 per cent. of the population (industrial workers). Any plan for health betterment should include 100 per cent. of the population. Good health pays. It should be demanded of the rich as well as the poor. We can well afford to extend our health department facilities so that we may know about the living and health conditions of all of the people.

How can this best be accomplished and by what agencies?

1. We must provide the private practitioner with the opportunity of higher standards of practice.
2. We must raise the standards of public health practice.
3. We should encourage the extension of industrial medicine.

These three factors will produce better health, lessen disease, and increase the number of working days, as well as working capacity, thereby reducing poverty and at the same time increasing the purchasing power for better standards of living, including the purchasing capacity of adequate medical service.

HIGHER STANDARDS OF PRIVATE PRACTICE THROUGH DIAGNOSTIC CLINICS

What share of the $500,000,000 loss which is charged to illness is due to unnecessary length of illness on account of lack of diagnosis, faulty diagnosis or faulty therapeutics? Loss from illness can be tremendously reduced through the establishment of diagnostic clinics so that 100 per cent. of the people may enjoy the advantage of the most scientific medical and surgical knowledge obtainable. These diagnostic clinical stations would afford to all physicians in their daily work the same facilities as extension courses and postgraduate work. It is difficult to imagine a better method of raising the standards of medical practice.

The group plan of practice, the furnishing of diagnosis, should be made free, or supplied at a minimum cost, so that 100 per cent. of the profession may keep in daily contact with the progress of scientific medicine by taking their patients to consulting clinics. Today in large cities 20 per cent. of the profession only have access to the scientific equipment of hospitals and public diagnostic research laboratories, and the 20 per cent. have these advantages at the cost of the 80 per cent. of the public and the 80 per cent. of the profession. By making diagnostic clinics free, or practically so, we shall enormously stimulate accurate diagnosis, systematic treatment, and preventive health work. These diagnostic clinics should be under the control of the health department. Health departments today make Widal tests, sputum examinations, Wassermann tests, diphtheria cultures, and send their men to confirm diagnoses of contagious diseases. The extension of this work to more complete diagnosis should not be objectionable.

Hospitals should primarily be teaching centers for all the physicians of the community as well as for medical students. Too often public and semipublic hospitals serve the selfish purposes of a fortunate few who, while claiming altruistic motives, deny to the profession at large, and therefore to the public, the educational advantages of hospital and clinical facilities. Specialism is all too rampant, and forbids the general practitioner a place in the sun.

THE SCHOOL DISPENSARY

The tremendous reduction in loss from illness occurring through the operation of industrial dispensaries suggests the extension of this principle to the schools. If full time physicians were placed in charge of all-day dispensaries in schools, making physical examinations of all children, and prescribing for their minor ailments, using the public diagnostic clinics previously referred to for confirmation of diagnoses, a similar reduction would take place in lost time from school as has taken place in lost time from work through the operation of all-day industrial dispensaries. Many universities have already instituted such medical supervision and care of the students. Industrial workers and schoolchildren comprise, perhaps, more than 80 per cent. of our population that would thus be reached by intensive preventive work and treatments in the daily clinics. The school dispensary in reaching out and supervising the child of preschool age, now utterly neglected, will serve a great social purpose.

THE IMPORTANCE TO PUBLIC HEALTH OF THE INDUSTRIAL DISPENSARY

If war has proved anything, it is that military success is dependent on industrial efficiency of the country. The health of the industrial units has loomed up as of paramount importance. We are equally concerned with the health of the individuals in these units in peace times, since they form the major portion of the community.

Perhaps the greatest change that has come in medical practice has been the development of the field of industrial hygiene. It is now taking the whole time of thousands of physicians in the medical supervision and care of employees, and it would seem that the beginning has just been made. No doubt this situation has been stimulated by workmen's compensation acts, but it is equally due to the awakening social consciousness on the part of the manufacturer. He has learned that the health of the worker is a definite asset in his business. Medical care in industry is not a charity. It pays good dividends. With the discussion for social insurance, we may look for a still greater extension of this work, and a more general employment of physicians in industry. The caring for occupational diseases, under workmen's compensation com-

Scientific attainment will come through the emphasis of the first. The application of this science to the ultimate social good will proceed largely through the latter two. All three together, through years of patient effort, will make for that final goal, adequate medical service.

In contrast to the stated [illegible] worker, and pressure for the elimination tionary growth [illegible] hazards. At the same time, the wage of heralded [illegible] worker is raised because such care increases his capacity for work and therefore still further reduces the necessity for charity in one form or another. It adds a new arm to the health department, and makes possible preventive medicine such as we have never yet dreamed of.

It does not take much imagination, therefore, to foresee the time when practically all of the industrial workers will be under daily supervision through industrial dispensaries. For the first time, then, we can begin to collect accurate data on morbidity. The very limited registration reflects the backward state of scientific preventive medicine. Absence from work is an economic question, and industry is going to know the reason why a man is off from work, and from what illness he is suffering. The employer is going to concern himself to the end that the employee's medical attention is of good quality. He will be interested in his food as well as in his housing problems. As to the claimed loss of nine days per year per man, or 0,000,000 on account of illness, private initiative, ugh the industrial dispensary, has shown that this can be reduced by one-half without charge on one but the employer, and this money is gladly spent because it is economically sound to do so.

Now the questions arise, What relationship will this new industrial medicine bear to public health work? Should it not have some kind of supervision from the health department so that its work may be best coordinated? And lastly, Would not industry cooperate in making industrial hygiene compulsory?

This type of socialized medicine will be intensively preventive, and entirely democratic; it will discover disease in its incipiency; it will prevent loss from illness instead of merely paying, through compulsory sickness insurance, a certain fraction of that loss; it will attack directly such problems as bad housing, venereal diseases, alcoholism and tuberculosis, and thereby make a fundamental contribution to social welfare. In comparison, the proposed sickness insurance bill is merely palliative, and actually tends to cover over and hide the various "social ulcers."

If we were to socialize medicine to the extent suggested, we would improve that time-honored and most desirable relationship between the family physician and patient. This immediate and definite response to social need would avoid the lowering of standards that is likely to come with the introduction of the panelized physician. Unless compulsory sickness insurance can be so devised as to place chief emphasis on prevention of disease rather than the giving of financial relief, it will actually jeopardize present health work by further reducing the present inadequate budgets. Through the socialization of medicine, the raising of the standards of medical practice, along with the extension of preventive work, illness to the industrial worker and to the rest of the public might well be reduced by one half. It would then follow that the distribution of the loss from nonpreventable diseases could more rationally be undertaken by some insurance plan.

It will be seen at a glance that his success and happiness are predicated on his health and that of his family; that this health is possible only through collective action, and that the family physician appears only who recognizes the close interrelationship between social work and medical work. These must be coordinately developed.

Let us now begin within the profession "a clean up and brush up campaign." Let us "put our own house in order." Let us be certain that we have given close attention to the social needs of the community. We may stand erect in the knowledge that we have always given unstintingly of our energy to make the world better for our living. If we are fully awake to our social obligations and opportunities, we need not commit the error of permitting well meaning reformers to mobilize our forces. It is our business to formulate social programs, not ours to accept, unchallenged, programs which place uneconomic burdens on us. Who are better equipped to write a social prescription than the members of the medical profession? Before making any additional sacrifices, we want to be "dead certain" that the other social groups are doing their part, and that the sacrifice is justified. If society at large will do her share in correcting her own evils, the medical profession can be counted on as always to cooperate and to do more than its share.

CONCLUSIONS

1. Private health practice and public health practice must be improved.
2. The knowledge of the prevention of disease, its diagnosis, and cure must be advanced.
3. Higher personal and ethical standards must prevail.
4. This better day will be hastened by a more general adoption of the group practice plan.
5. More men must fit themselves for the distinct specialty of industrial medicine.
6. The supervision of schoolchildren and children of preschool age should be extended through the establishment of school dispensaries.
7. These methods together will constitute an adequate medical service, and be a forward step in the ultimate socialization of medicine.

ABSTRACT OF DISCUSSION

Mr. Lee K. Frankel, New York: The fundamental error that has been made in the dicussion of this subject is due to lack of realization as to what insurance means. Primarily, insurance has no thought of prevention. The advocates of social insurance have said much about the proposed compulsory insurance bill carrying with it prevention of sickness. If we will only realize that, fundamentally, insurance is not prevention, but that it is indemnity for loss, we may get together on a basis for legislation satisfactory to all. Health insurance, basically, is intended to replace wages which individuals lose by illness. This is a comparatively simple matter: it means the preparation of a morbidity table in order to determine the cost. So far as this payment of claims is concerned, insurance involves the medical profession; but it involves it only in so far as the skill of the medical practitioner is required to determine whether the individual who claims benefit is or is not entitled to benefit.

Where the confusion has arisen, not only here, but abroad as well, is in the fact that the medical practitioner has been expected to perform this one primary and important function, but, in addition thereto, to give medical treatment and care. When you realize that medical men have deliberately banded themselves together, have gone on so-called strikes, and have refused to give treatment, in absolute opposition to the ethics of the profession, you can realize what social health insurance in Germany has developed. If there is one thing we want to avoid, it is the repetition of that in the United States. The question of medical care, the question of treatment, is a thing apart from the payment of cash benefits. Whether we shall get away from the theory of the individual medical practitioner, with his fee, and have salaried medical practitioners, cannot be determined by the outsider; it must be determined by the profession itself; and until the profession has given careful consideration to this matter, has come to some agreement, we cannot develop any efficient and thorough scheme of sickness insurance in the United States.

Dr. Joseph Goldberger, Washington, D. C.: In my judgment there is no matter that is likely to be such a powerful incentive for the exercise and practice of preventive medicine as health insurance. As an illustration of the principle involved, I want to cite the parallel phenomenon that we are seeing at the present time in connection with preventive medicine in a field related to health insurance, namely, life insurance.

Now, you all, I think, know the splendid work that the Metropolitan Life Insurance Company, for instance, is doing toward the conservation of health and the prevention of death, simply because it finds that it is a matter of dollars and cents; that it is a matter of economy to prevent death. Now, it seems to me that when we have some system of health insurance, then the prevention of sickness will become a profitable business to the organization insuring against sickness. When it comes to the question of organization and administration, that is a matter about which I have no opinions. The point, however, that I wish to emphasize, and that I think is of fundamental importance, is the one that I have just mentioned: that health insurance makes the conservation of health and the prevention of sickness a matter of dollars and cents, a most potent and driving force.

Dr. Otto P. Geier, Cincinnati: May I insert a comment on Dr. Goldberger's statement as to the likelihood of economic pressure bringing about preventive work? If he will go to Ohio and study the workmen's compensation law and see the ever-increasing cost per $100 of insurance in the various industries, and note how relatively indifferent the manufacturer is to that increasing cost, he will take a different view as to the rapidity with which people will respond to preventive work under social insurance because of economic pressure. What actually happened was that industry opposed the workmen's compensation act. Once adopted, the industries accepted the situation and the rate per $100 of pay roll for each class of industry. When the rate went up 5 cents, 10 cents, 15 cents, 20 cents per $100, little or no attention was paid to it. Industry had acquired an immunity against any economic reaction. The fact remains that industry is not trying to reduce accident through a desire to reduce the rate. The real reason for industry's interest in reducing accidents is a realization that the man's absence is expensive because of the lowering of production, and because by reducing accidents industry also reduces the expensive labor turnover.

Detecting Adulteration in Tea.—A new method of detecting adulteration in tea has been described by L. Rehfous in the *Bulletin* of the Botanical Society of Geneva (Switzerland). It involves an examination of the stomata, which are quite different in *Thea sinensis* from those of the leaves used for adulteration. In *Thea* the guard-cells of the stomata possess, on their inner surface, a very strongly marked layer of cutin, which is prolonged into a beak or hook, and which is distinct from the beak which closes the ostiole. Mr. Rehfous finds these features, with minor variations, in all of numerous kinds of tea examined, and they appear even in the sepals of the tea plant. The only leaf used for adulteration that bears much resemblance to *Thea sinensis* is the leaf of Camellia (also a species of *Thea*), but a transverse section of the latter shows that the hooks of the stomata are very slightly developed.—*Scientific American.*

A CRITIQUE OF BANTI'S DISEASE*

ELI MOSCHCOWITZ, M.D.
NEW YORK

INTRODUCTION

The disease described by Banti has received fair attention from writers on clinical medicine, but curiously, very little from pathologic anatomists, and rarely from both. As a consequence, the literature on Banti's disease affords a most disjointed impression, and leaves little material on which to base an estimate of the validity of Banti's disease as a nosologic entity. Indeed, in order to form a clear idea as to what Banti's disease is, it is necessary to turn to the articles written by Banti himself. Then we find that one of two things has happened. Either the observer has not taken sufficient pains to find out Banti's own specifications, or he has frankly committed himself to Banti's views, without the slightest, or only faint-hearted, attempts at criticism. Practically the only criticism of Banti's views has come from pathologists and, significantly enough, the general tone of it is one of guarded skepticism. We therefore meet with the strange phenomenon of a disease being almost whole heartedly accepted by clinicians, and only negatively, so to speak, by pathologists. As an attempt at reconciliation of these two views various modifications of Banti's conceptions have been proposed, which have resulted only in making "confusion worse confounded," so that nobody, not even Banti himself, as I shall show, knows definitely what Banti's disease connotes.

It seems necessary, therefore, to resurvey our ground and subject the vast data that have been gathered to a comprehensive critique, in the light of both clinical medicine and pathologic anatomy.

REPORT OF CASES

This study was instigated by the report of the following two cases:

Case 1 (Beth Israel Hospital Pathologic Report 4467).—*History.*—M. W., a man, aged 60, married, admitted July 25, 1913, for one year had complained of general weakness, which slowly increased. For the last half year, he noticed a yellow tint of the skin. He had gone to bed five weeks previously with swelling of the ankles and feet. At times he had slight vertigo. There were urinary, respiratory or digestive symptoms.

Physical Examination.—The patient was emaciated and had edema of the ankles and the eyes. There was evidence of profound anemia, and the skin had a yellow tinge. There were signs of a chronic tuberculosis of both lungs. The left heart was dilated, with a rough systolic murmur in the pulmonic region. The liver was palpable 3 inches below the costal margin. The spleen extended from the seventh intercostal space to the level of the umbilicus; its edge was irregular; it was soft in the upper and hard in the lower portion. The abdomen contained fluid. The blood count on admission revealed 2,850,000 erythrocytes. These were progressively reduced until two days before death, when they were 1,200,000. The leukocytes were 7,000 on admission, and varied around this number throughout the patient's illness. The hemoglobin was 35 per cent. at the outset; a day or two before death it was 10 to 14 per cent. There was evidence of anisocytosis and poikilocytosis, and occasional microblasts were present. The temperature varied between 98 and 100 F. The pulse was not rapid. A test meal revealed blood in the gastric contents. The clinical diagnosis was Banti's disease. The patient died, Dec. 8, 1913.

---

*From the Pathological Laboratory of the Beth Israel Hospital.

* Read before the Section on Pathology and Physiology at the Sixty-Eighth Annual Session of the American Medical Association, New York, June, 1917.

Anatomic Diagnosis.—Necropsy revealed emphysema and healed tuberculosis of both lungs, chronic pleurisy with adhesions, hypertrophy and dilatation of left ventricle, atheroma of aorta, thrombotic fibrous angioma of liver, chronic diffuse nephritis and splenomegaly. The spleen measured 24 by 20 by 15 cm. and weighed 1,165 gm. (liquor formaldehydi). It was densely adherent to the costal wall, and the capsule was thick, dense and resembled *Zuckerguss* (sugar-icing) in appearance. In the upper part of the convex surface was a shallow depression in which the capsule was unusually thick. Section through this area revealed a thin plaque of lime. The pulp was firm and elastic. It was a deep reddish-purple, and the surface was smooth. The pulp did not scrape. Connective tissue trabeculae, both large and small, were enormously increased. The larger trabeculae were especially prominent and sprang forward from the cut section. Malpighian corpuscles were not visible.

The liver presented a slightly nutmeg-like appearance. There was no cirrhosis.

Microscopic examination revealed chronic congestion and chronic tuberculosis of the lungs; brown pigmentation of the heart muscle; slight chronic congestion of the liver (no cirrhosis); slight interstitial pancreatitis, and marked chronic diffuse nephritis.

The capsule of the spleen was much thickened, and in places showed areas of hyaline degeneration. The predominant lesion was a profound fibrosis. The new connective tissue was either pure fibrous and surrounded the splenic veins, or was more cellular and then appeared as masses or strands throughout the organ. The pulp was deeply engorged with red blood cells. The pulp cells showed a marked diminution in cellular content. The cells consisted mostly of lymphocytes; many cells were of the plasma type; there were a few large cells of the endothelial type and a few large multinucleated cells. The splenic veins were normal in size. Their lining epithelium was not swollen. The trabeculae were enormous in size. Their blood vessels showed thickening. The malpighian bodies were few in number and very small. A small number showed fibrosis proceeding eccentrically from the central artery. There was no blood pigment. The splenic veins in the pedicle showed enormous thickening of the intima, forming veritable projections into the lumen. The walls showed a profound increase in connective tissue with hyaline degeneration. There were extensive lime deposits in the walls of the veins. The arteries showed slight thickening. Sections of spleen and vessels stained by Levaditi's method showed no spirochetes. The lymphatic glands were normal.

Case 2 (Beth Israel Hospital Pathologic Report 7288).—*History.*—R. K., a woman, married, aged 47, Russian, housewife, admitted, July 15, 1916, never had had children, but had had twelve miscarriages. Her illness dated back twelve years, when she was sick for some months with an attack similar to the present. She had hemorrhages from the mouth and bowels, with swelling of the abdomen and feet. Ten weeks previously she had had a hemorrhage from the mouth and bowels. She also noticed at that time swelling of the abdomen and feet; her appetite was poor; she had occasional nausea but no vomiting; she had precordial pain with palpitation and occasional fainting spells, occasional headaches, and much weakness, and had lost considerably in weight.

Physical Examination.—The patient was pale and emaciated. The spleen extended nearly to the umbilicus; it was hard, rough, irregular and lobulated in outline. There was much fluid in the abdomen. The other organs were negative. The red blood count was 3,460,000; leukocytes, 14,200; hemoglobin, 50 per cent. The differential count gave: polymorphonuclears, 85 per cent.; lymphocytes, 12 per cent.; eosinophils, 3 per cent. The feces were tarry and give a reaction for blood. The temperature and the pulse were normal. The Wassermann reaction was negative.

The abdomen was tapped twice, and each time from 9,000 to 10,000 c.c. of clear fluid were withdrawn.

The clinical diagnosis was Banti's disease. The patient died, Aug. 18, 1916.

Anatomic Diagnosis.—Necropsy revealed brown atrophy of the heart muscle; slight atheroma of mitral and aortic valves; healed tuberculosis of the bronchial lymph nodes; chronic perihepatitis; slight chronic congestion of the liver, but no cirrhosis; chronic diffuse nephritis; chronic peritonitis, and splenomegaly with multiple healed infarcts containing lime and bone.

The spleen measured 25 by 15 by 7.5 cm., and weighed 3,840 gm. The surface was irregular and lobulated, with numerous deep depressions to which, as a rule, the omentum was densely adherent. At its upper part a portion of the spleen about the size of a baseball had been almost completely cut off from the remainder of the organ by a deep fissure. There were numerous other deep depressions due to the scars of healed infarcts. Most of these scars contained lime, and some of them bone. The deep fissure described above contained an unusually large plaque of bone. The capsule was distended, and averaged about 4 mm. in thickness. On section, the parenchyma was brownish red; the pulp soft and elastic; it did not scrape or spring forward from the cut section. The trabeculae were much increased, both in size and in number. The malpighian bodies were not visible. The splenic veins and artery at the hilum were much thickened and calcareous.

Microscopic Examination.—There was brown degeneration, chronic congestion and slight fatty infiltration of the heart muscle. The liver showed no cirrhosis. There was a moderate grade of chronic parenchymatous nephritis. The other organs showed nothing of significance.

The capsule of the spleen showed thickening and hyaline degeneration. The predominant aspect was that of a profound fibrosis. The organ appeared like a huge angioma, the splenic veins being round or spindle-shaped and were surrounded by dense masses of splenic pulp which had undergone almost complete fibrous change. Much of this new fibrous tissue was hyaline in character. The pulp contained comparatively few cells. These were mostly of the lymphoid and plasma type, with a few large endothelial cells. The endothelium of the splenic veins was not swollen. The malpighian bodies were almost completely absent; here and there was a small group of irregularly arranged lymphoid cells which represented the remains of the malpighian bodies. The trabeculae were enormously increased in size, and their containing vessel showed thickening of the walls with hyaline degeneration. The infarcts showed an almost complete transformation into hyaline connective tissue; nearly all contained lime and some contained bone. There was no blood pigment in the spleen.

The splenic vessels at the hilum showed a connective tissue infiltration so profound that little muscular tissue was left in the walls, and the normal structure was almost completely obliterated. This new connective tissue also showed hyaline degeneration. There was much deposition of lime in the outer coats of the vessels. Sections of spleen and vessels stained by the Levaditi method showed no spirochetes. The lymphatic glands were normal.

COMMENT

Reviewing the clinical features of these two cases we find the following:

The first case was that of a man, aged 60, who had been suffering for one year from a rather profound anemia which progressively increased. During his stay in the hospital, there had been a pronounced splenomegaly, a moderate ascites, and, as the necropsy revealed, a healed tuberculosis of both lungs. In addition the patient had presented a blood condition corresponding to that of a secondary anemia. Despite the short history and an absence of a relative lymphocytosis, the diagnosis of "Banti's disease," had seemed the only one possible and had accordingly been made.

The second case was that of a woman, aged 46, who had been ill for twelve years, and had given a history of hemorrhages from the mouth and bowels. Very significant had been the history of twelve miscarriages. There had been splenomegaly, a secondary anemia, and an enormous ascites which required tapping. The Wassermann reaction had been negative. In this case all the evidence, both clinical and physical, had seemed typical of Banti's disease.

Reviewing the pathologic findings in these two cases we find many things in common: (1) an enormous splenomegaly, each spleen weighing well over 1,000 gm.; (2) a diffuse fibrosis with persistence of the splenic veins and a consequent diminution in cellular content of splenic pulp; (3) a much thickened and partly adherent capsule; (4) a notable diminution in size and number of malpighian follicles, a change in many instances due to progressive fibrosis proceeding from the central artery; (5) a pronounced endophlebitis of the veins in the hilum of the spleen, where there are, in addition, calcareous plaques; (6) thickening and hyaline degeneration of many of the vessels in the trabeculae; (7) absence of general glandular enlargements; and (8) the liver free from cirrhosis.

DEFINITION OF TERMS "SPLENIC ANEMIA" AND "BANTI'S DISEASE"

In accordance with these clinical and pathologic data, what generic pathologic diagnosis is justified? In other words, do the pathologic findings bear out the clinical diagnosis?

In order to answer this question, a brief discussion of certain forms of the nonleukemic splenomegalies is necessary.

In 1866, Gretsel[1] defined a syndrome which Griessinger termed "splenic anemia." The essential features of this disease are (1) primary cryptogenetic splenomegaly; (2) secondary anemia, and (3) chronicity.

In 1894, Banti[2] believed that he isolated a syndrome and pathologic complex from this broad clinical entity. According to Banti this disease has clinically three stages: (1) a period lasting from three to five, but occasionally even twelve years, characterized by a splenomegaly of practically constant size, and an anemia; (2) a short second period characterized by swelling of the liver with diminution of the quantity of urine, and (3) a final period which lasts one or two years, and is characterized by a small liver and ascites. The symptoms in this stage, according to Banti, are identical with those of an ordinary atrophic cirrhosis. The disease invariably ends in death from hemorrhage, or autointoxication from the cirrhosis. The disease is without known etiology. The most common causes of splenomegaly, such as alcohol, malaria and syphilis, play no rôle whatever.

In addition to the symptoms enumerated above, Banti's disease is characterized by hemorrhages from the mouth and the bowel, an icteric skin hue (but no true icterus), and a secondary anemia distinguished by a subnormal leukocyte count with a relative lymphocytosis.

Pathologically, Banti[3] now maintains what he did not assume in his earlier papers, namely, that the disease has a distinct pathology. These manifestations are the following: 1. In the spleen there is a fibrosis of the reticulum, with narrowing of the splenic veins and a thickening of the capsule and of the coarser and finer trabeculae. 2. The main characteristic of the lesion is a fibrosis of many of the malpighian follicles beginning around the central artery of the follicle and proceeding outward. The artery often shows hyaline degeneration. These changes he termed "fibroadenie," because, despite the increase in connective tissue content, the histologic structure of the spleen still retained its glandular appearance. According to Banti, the connective tissue is not of inflammatory origin, because he has never seen anything resembling fibroblastic granulation tissue in these spleens. There is no blood destruction as evidenced by the absence of blood pigments. 3. A cirrhosis of the liver is present differing in no way from that of the Laennec type. 4. In many cases there is an endophlebitis and often a calcification of the splenic veins, extending sometimes to the junction with the portal vein, and even within the portal vein itself. 5. The characteristic red marrow of a secondary anemia is found. 6. Freedom from general grandular enlargement is noted.

In explaining the pathogenesis of the disease, Banti believed that there is a primary splenomegaly due very probably to an infectious agent. The enlargement of the organ produced in turn another toxin which caused a secondary cirrhosis of the liver and the changes in the splenic veins. The anemia is the result partly of the toxemia and partly of the hemorrhages.

Banti's reasons for believing that the splenomegaly is primary are the following: (1) the large size of the spleen at a time when the anemia is not marked; (2) the microscopic lesion seeming to show that the "fibroadenie" antedates the cirrhosis of the liver; (3) the spleen in Banti's disease showing no evidence of *stauung*, a feature characteristic of the spleen in hepatic cirrhosis, and (4) the cures obtained by splenectomy.

In analyzing the clinical and pathologic features of the disease called by his name, we find that Banti has hedged his malady about by so many criteria that it is almost unreasonable to expect any single case to conform to every requirement.

These requirements are clinical and pathologic, and may be classified as follows: 1. The disease must be without known etiology. As soon as a definite cause for the malady is established, the case is no longer regarded as a possible "Banti," but is at once thrown out of court. 2. The blood picture must be typical. 3. There must be three stages, two of which are fairly well defined clinically. 4. The signs of anemia and splenomegaly must precede the cirrhosis.

Pathologically the data which make a diagnosis of Banti's disease possible are the following: (1) a splenomegaly of considerable size; (2) a cirrhosis in the liver of the Laennec type; (3) a histologic fibrosis of the spleen arising without the interposition of fibroblasts; (4) a progressive eccentric fibrosis of the malpighian follicles, and (5) a usual but not constant endophlebitis of the splenic vein.

Banti admits that there is nothing pathognomonic in the pathologic findings. It seems, therefore, that the diagnosis of Banti's disease must be made by a combination of both clinical and pathologic data. In other words, no matter how clear the clinical diagnosis of Banti's disease may be, unless the pathologic findings are those premised by Banti, the disease is not Banti's disease. On the other hand, even if the characteristic pathologic findings are present, unless the history of the case is typical, the diagnosis of Banti's disease must not be made.

[2] Banti: Sperimentale, 1894, **48**, 407.
[3] Banti: Folia haemat., I, 1910, **11**, 1.

As a consequence of this dual interpretation, the confusion in regard to the status of Banti's disease as either a clinical or pathologic entity is truly amazing.

Banti has found a few adherents, but by far a greater number of opponents. I have already stated that, as far as I can judge from a study of the literature, his adherents are usually the clinicians, while the pathologists are nearly all his opponents. In this critique of the opposing views, I shall try: (1) to submit the argument pro and con that Banti's disease is a distinct entity; (2) to discuss the relation of this disease to allied morbid states; (3) to discuss certain curious features relating to the pathology of this disease, and (4) to suggest certain problems arising from this study.

ARGUMENTS FOR AND AGAINST BANTI'S DISEASE AS A DISTINCT ENTITY

At the outset we shall admit that the clinical picture described by Banti is sometimes seen. Every clinician with any experience will vouch for this fact. In other words, there are unquestionably patients who, for no obvious cause, show symptoms of long-standing anemia with splenomegaly, and these patients after a lapse of years develop ascites and die. It is also admitted that at necropsy the lesions described by Banti are found.

On the other hand, the literature teems with varia-ns from this general type. These will be discussed iatim.

1. As to the etiology of Banti's disease, a large number of clinically typical cases have been reported due to syphilis (Marchand,[4] Chiari,[5] Schmidt[6] and Krull[7]). In Schmidt's case, in fact, the disease was cured by salvarsan.

Kartulis[8] reports ten cases of clinically typical Banti's disease, in which plasmodia were found in the spleen. Skubetsky[9] reports a typical Banti's disease (splenomegaly, anemia, ascites and leukopenia) due to tuberculosis of various serous cavities.

Furthermore, there is a host of accurately described and clinically typical cases of Banti's disease in which the symptoms and findings simulated those of a Laennec cirrhosis so closely that the authors believe these two diseases to be identical. I shall discuss this part of the subject more extensively farther on.

Neuberg[10] summarizes his own views by saying that there are many case reports of clinical Banti's disease without known etiology, but with other pathologic findings than those described by Banti; while on the other hand there is an equally large number of case reports in which the characteristic lesions are described, but which have a definitely determined etiology.

2. Is the blood picture characteristic of Banti's disease? I have found the characteristic blood picture in various conditions in which the diagnosis of Banti's disease did not enter. The blood picture appears to be nothing more than the changes associated with any secondary anemia. Hedenius[11] concurs in this view. Banti in his most recent publication admits that the blood picture "is not pathognomonic but only helpful to the diagnosis."

3. Are the stages of the disease described by Banti invariable and is the cirrhosis always secondary to the splenomegaly? In other words, is a cirrhosis of the liver always absent in the first stage of Banti's disease and is it always present in the last stage? If, then, a patient dies with all the symptoms of Banti's disease and at necropsy no cirrhosis is found, must we diagnose Banti's disease in the first stage, or is the case not Banti's disease at all? And if the case is not Banti's disease, in what category may it be placed? The formulation of Banti's disease as occurring in stages has probably caused more of the hopeless confusion in regard to the interpretation of the disease than any other factor.

Numerous cases of clinically typical Banti's disease have been described in which at necropsy no cirrhosis was found. My two reports are cases in point. On the other hand, there is a host of reported cases with the characteristic pathologic changes, but with symptoms so typical of those which Banti described that they were regarded by their observers as cases of true cirrhosis of the liver.

Banti himself is not clear on this point. He admits that patients with clinical Banti's disease may show at necropsy no cirrhosis of the liver. In attempting to place these cases in their proper sphere he suggests a number of possibilities: (*a*) that they represent first stages of Banti's disease, and that in these cases the splenotoxin expended itself in merely creating a fatal anemia and not a cirrhosis of the liver; (*b*) that the lesion may be due to another toxic agent; (*c*) that after all there may be two nosologic entities: a splenomegaly with cirrhosis and a splenomegaly with anemia. Finally, he adds to the confusion by describing the pathologic findings in the first stage of what he himself regarded as genuine cases of Banti's disease. In such cases, he finds no cirrhosis. But the question arises, in view of the foregoing dicta set forth by Banti, How does he know that these cases were in the first stage? For, as I understand him, the diagnosis of Banti's disease is not justified unless cirrhosis is found postmorten.

We thus see from these three points of view, the most important among the clinical phases, that Banti's disease has most indeterminate outlines.

Let me now offer a critique from the pathologic-anatomic aspect.

4. What evidence is there for Banti's contention that a splenotoxin is a secondary cirrhosis of the liver? These are purely hypothetic assumptions, and are based on the fact that clinically the splenomegaly seemed to antedate the onset of the hepatic cirrhosis. The only scientific evidence that such a toxin is developed by the spleen in Banti's disease is the report of Umber,[12] who found in metabolism studies in one case that there was a protein destruction which disappeared after splenectomy. This observation has never been confirmed. Furthermore, the only experiment showing that a splenotoxin may cause changes in the liver is that of Mallory,[13] who, after causing extensive trauma to the spleen, found focal necrosis in the liver. This observation has been cited by various observers as upholding Banti's contention; but, according to my view, the arguments are only too specious. In the first place, dead tissue is not a toxin;

and secondly, focal necrosis in the liver is not, nor does it ever bring about a cirrhosis.

Even from the hypothetic standpoint, the pathogenesis as described by Banti is difficult to conceive of. We must remember that Banti wishes us to believe that an extensive fibrosis of the spleen is the result of an unknown toxin, and that, furthermore, this fibrous spleen elaborates another toxin which acts directly on the liver. In the first place, the transference of a sclerosing toxin from one organ to another, has, as far as I can determine, no analogue in pathologic anatomy. If a sclerosing toxin is elaborated within the human body, it affects two or more organs simultaneously. Moreover, it is difficult to comprehend how an organ so extensively fibrous as a spleen in Banti's disease can elaborate a toxin that will in turn have sclerosing properties.

5. Are the histologic characters of the spleen described by Banti pathognomonic? Even Banti admits that these lesions are not pathognomonic of Banti's disease. Fibrosis of the spleen is, of course, found in a host of other conditions; in cirrhosis of the liver, for instance. Even what Banti regards as the most characteristic histologic detail, the eccentric fibrosis of the malpighian follicles, is not pathognomonic of his disease. My cases reveal this lesion, although in the strictest interpretation they are not cases of Banti's disease. The same holds true for the other associated lesions described by Banti.

All in all, it is well agreed by everybody, even by Banti himself, that a pathologic diagnosis of Banti's disease is impossible on the basis of the pathologic findings alone (Simmonds,[14] Neuberg, Marchand, Wentworth,[15] Kaufmann,[16] Hedenius, Borissowa,[17] Schewandin[18] and Naunyn[19]).

6. What evidence is there that the fibrosis of the spleen is a primary sclerosis and is not of inflammatory origin? Banti maintains that the process is a primary sclerosis because he does not see fibroblasts in the spleens of Banti's disease. This argument, to my mind, is weak. In the first place, cells resembling fibroblasts are seen in such spleens. Chiari, indeed, who in some particulars leans to Banti's views, asserts without hesitation that the fibrosis in Banti's disease is identical with the splenic fibrosis of any other origin. In the second place, the distinction between a fibrosis that arises from a so-called "primary sclerosis" and one of "inflammatory origin" is entirely an academic one, and is not countenanced by authorities in pathologic anatomy.

7. What is the evidence in favor of splenectomy as a cure for Banti's disease? In all his publications Banti has been advancing the beneficial results of splenectomy as one of the prime arguments in favor of the primary splenic origin of his disease. This statement, like many others that Banti has made, is much quoted in the literature of this subject.

I feel, however, after analysis of the reported cures, that this statement cannot be accepted without much hesitancy. A study of the reported cases shows either that (1) no proof is offered that the disease described conformed to Banti's specifications, or (2) the "cures" are reported altogether too soon after the operation.

1. Harris and Herzog,[20] who summarized all the reported cures up to 1901, describe unquestionable cases of Gaucher's disease in the number. Wentworth, who also is skeptical of reported cures of Banti's disease by splenectomy, reports a so-called "cure" that proved to be a syphilis of the liver. Marchand reports a similar instance. Naegeli-Nef[21] and Hedenius also believe that many of these reported cures are of maladies other than Banti's disease.

2. The second consideration that arouses scepticism is the fact that the cures are reported too soon after the operation. This is the criticism applicable to the majority of reported "cures." When we consider that even in the third stage a patient may live as long as five years, a cure reported within this time is not of profound significance. In one of the cases that I report, the patient lived for twelve years after the onset of the symptoms.

The most recent summary of splenectomies for Banti's disease that I have been able to find is that of Armstrong,[22] published in 1906. Of the thirty-two reports, only four were made five years after operation. In Banti's latest paper, he collects thirty-six instances with twenty recoveries. He says that two patients operated on in the "first stage" in 1895 and 1904, respectively, and two patients operated on during the "second stage" in 1896 and 1903, respectively, are well. He also makes the cryptic statement that patients operated on in the third stage afford good results. These few cases are all that I can find that in any way sustain splenectomy as a therapeutic measure for Banti's disease. The whole question of splenectomy as a cure for Banti's disease is paralleled, I believe, by our experience with splenectomy as a cure for pernicious anemia. With the first reports, its value seemed to be established; but as soon as sufficient time had elapsed to permit the observation of end-results, it was found that these patients with pernicious anemia succumbed despite the splenectomy, and that the splenectomy produced only a temporary improvement.

RELATION OF BANTI'S DISEASE TO ALLIED MORBID STATES

1. *Cirrhosis of the Liver.*—Banti's disease very closely resembles cirrhosis of the liver, both clinically and pathologically. Indeed, the view that the two conditions are identical is held by many, perhaps even by the majority of Banti's critics (Simmonds, Albu,[23] Gilbert and Lereboullet,[24] Krull, Naegeli-Nef, Naunyn and Wentworth).

Obviously the first argument that would occur to one in order to refute this identity is the different sequence of clinical events. In Banti's disease, a primary splenomegaly is followed by signs of cirrhosis, while in typical Laennec cirrhosis, the reverse is the rule. Nevertheless, I have seen cases of Laennec cirrhosis, and Krull, Naunyn, Wentworth and Marchand report similar experiences, in which splenomegaly is so profound as to mask the symptoms arising from the lesion within the liver.

Pathologically, also, the spleen of a Laennec cirrhosis and that of Banti's disease are in many respects alike. Both are distinguished by splenomegaly, fibrosis and atrophy of the malpighian follicles. In cirrhosis, it is true, the fibrosis is not so profound, and there is greater evidence of *Stauung* and hyperplasia of the pulp.

In view, therefore, of the criteria which Banti adduced, a differentiation between Banti's disease and cirrhosis of the liver appears easy. However, when we consider the indefinite outlines, both clinical and pathologic, of Banti's disease, and on the other hand, the very close clinical and pathologic similarity of cirrhosis of the liver and Banti's disease, we can readily understand why so many authors regard the two maladies as identical. A precise differentiation will always be difficult when we must deal, as regards one factor at least, with a purely clinical entity.

2. *Relation of Banti's Disease to Splenic Anemia.*—This relation is a question that has puzzled nearly every one interested in this subject. Nor is it hard to understand the reason, when we consider that the term "splenic anemia" was ascribed by Griessinger to a purely clinical condition. It is thus a term of wide connotation and can be safely applied to any condition in which a splenomegaly of unusual size is associated with an anemia of whatever grade or type.

Since Griessinger's original communication, a number of fairly distinct forms of splenomegaly associated with anemia have been split from this broad group; for instance, the splenomegalies of the Gaucher type, which has a sharply defined pathologic and histologic picture; also the peculiar anemia occurring in children, known as von Jaksch anemia,[25] which has a sharply defined blood picture of its own. And now comes Banti, who also parcels off a portion of this "medical Poland" as his own. And what have we left? According to Banti, only such cases as are fatal and at necropsy show no cirrhosis. Even these cases Banti does not permit to slip out of his hand so easily, because he still feels that they may be cases of Banti's disease in the first stage. If this is admitted, then splenic anemia as an entity disappears completely. On the other hand, Naunyn is willing to call only such cases Banti's disease as are distinguished by splenomegaly without cirrhosis; that is, cases that were formerly termed "splenic anemia"; and Senator[26] says that a Banti disease is only a second stage of a splenic anemia; that is, a combination of splenic anemia and cirrhosis of the liver. The pronouncements of Senator and especially Naunyn are unfair, because Banti should be left to define his disease as he thinks best. If all of Banti's claims are then recognized, we shall arrive at what I regard as the most significant conclusion arising from this study, namely, that Banti's disease and splenic anemia are one and the same thing.

3. *Relation of Banti's Disease to Pseudoleukemia.*—At one time, according to Wentworth, Banti believed that the disease called by his name was the splenic form of pseudoleukemia. But in his most recent paper (1910) Banti does not even mention this name in connection with his disease. This is justified in view of the entirely different histologic characters of the spleen in pseudoleukemia and in Banti's disease.

TO THE PATHOLOGY OF BANTI'S DISEASE

Banti describes a pronounced endophlebitis and often calcification of the portal vein and its tributaries. He believed that this lesion was the result of the action of the splenotoxin on the intima. This lesion has been described many times in connection with this malady, notably by Dock and Warthin,[27] Levastini and Bloch[28] and Bonné.[29] My two cases present this lesion in a profound degree. Furthermore, other observers, Cauchois,[30] Edens,[31] Nonne, MacCallum,[32] Devé,[33] and Oettinger and Fiessinger,[34] report extensive thrombosis in the splenic and portal veins, arising either from an endophlebitis or without known cause, and associated with splenomegaly. The question arises whether Banti is right in his interpretation, or whether the splenic disease may occur as a consequence of the lesion in the vein. Warthin[35] raised this question and instituted experiments consisting in ligation of the splenic veins in dogs. He found that this operation resulted in no increase in the size of the spleen, but rather in an atrophy. Others believe that the splenomegaly is the result of the thrombosis. Cauchois, especially, devotes a lengthy thesis to prove the latter hypothesis, and attempts to make a separate group of cases presenting the Banti syndrome associated with pylothrombosis. His arguments are by no means convincing. This question can therefore safely be left open. The difficulty arises from the fact that sufficient data are not yet available to show whether an endophlebitis with or without calcification occurs unassociated with splenomegaly. In other words, this vein lesion may eventually prove to be entirely an incidental one, and not either a cause or an effect.

On the other hand, it is easily conceivable, indeed, very probable, that the endophlebitis of the splenic vein may cause an ascites in cases that present no cirrhosis of the liver. This may account for the many cases of clinical Banti's disease in which no cirrhosis is found post mortem. This is what probably occurred in my two cases.

SIMULATION OF BANTI'S DISEASE BY PERSISTENCE OF THE UMBILICAL VEIN

These cases are to my mind of much significance as pointing to a possible clue to the origin of many forms of splenomegaly, inclusive of that associated with the name of Banti. Four such cases have been described in comparatively recent times by Cruveilhier,[36] Baumgarten,[37] Masura[38] and Benque.[39] The clinical picture in all was that of Banti's disease. In addition there was hypoplasia of the liver, which these observers agreed was probably a result of the persistence of the umbilical vein. At necropsy, this vein was found enormously dilated, and communicated in some cases with the deep hypogastric or the deep epigastric vein. The excessive amount of blood which this vein carried into the portal sinus overtaxed its capacity and caused a stasis in the splenic vein. In this manner, the authors accounted for the enormous splenomegaly.

These cases seem to me to indicate the possibility that the splenomegaly of some cases of Banti's disease may be of primary vascular origin after all.

---

[25] Some question has recently been raised as to the validity of this form of anemia as a distinct type. Some observers hold that it is only a form of secondary anemia with a profound blood reaction, owing to the heightened susceptibility of the bone marrow in children.

THE AUTHOR'S CONCEPTION OF BANTI'S DISEASE

I would deem this communication futile were its theme one of destructive criticism only. My critique, thus far, transports one, as far as the subject of primary splenomegaly with anemia is concerned, practically to the period antedating Banti's publications; not entirely, however. We give credit to Banti for stimulating investigation of an obscure malady, for elucidating much of the pathology of the condition, and for elaborating the clinical phenomena. What substitute, then, can be offered for Banti's conception, and where can the disease that he describes be correctly placed in nosology?

My study and reflection lead me to the following views:

1. All the evidence thus far submitted gives us no right to believe that splenic anemia and Banti's disease are not identical.

2. There is no reason for differentiating Banti's disease from other splenomegalies associated with anemia on the ground that in Banti's disease no etiology can be determined. A nosologic distinction based on whether a disease has a known or unknown etiology has no *raison d'être* in clinical medicine. Rather, I believe, we should regard Banti's disease as merely a nosologic and clinical entity which may be due to both known and unknown causes. The known causes are syphilis, alcohol, malaria, trypanosomiasis, persistence of umbilical vein, etc. In all these maladies, a splenomegaly, an indurative splenitis, with eventual atrophy of the malpighian follicles, and an anemia are the predominant features.

It may be argued that in the splenomegalies associated with alcohol, malaria, syphilis, etc., the causes of the disease and some of the clinical phenomena differ from those which Banti described. In reply, I answer: 1. Banti's disease has no typical course and diagnostic symptoms; indeed, if the specifications which Banti predicated are strictly adhered to as criteria for making a diagnosis, we would find that Banti's disease is extraordinarily rare. 2. A clinical diagnosis of Banti's disease has been made by most able clinicians in cases that eventually prove to be cirrhosis of the liver, malaria, syphilitic splenomegaly, etc. I have cited such instances in this communication. Again, it may be argued that the pathology of Banti's disease is quite different from that of the splenomegalies of known origin. But, as I have already pointed out, the pathology of Banti's disease is by no means a specific one. The fact that many observers hold that Banti's disease and cirrhosis of the liver are identical shows that this contention is not unjustified. 3. I believe that Banti's explanation of the cirrhosis of the liver as secondary to the splenotoxin is wrong. The reasons for this belief I have already discussed. Furthermore, I do not believe that patients who show at necropsy no cirrhosis of the liver should, as some hold, be regarded as affected with a different malady, or that such cases should be regarded, as does Banti, as instances of Banti's disease in the first stage.

I believe it is more logical and would simplify matters considerably to regard these variations as phenomena of one and the same disease; that a fibrogenetic toxin, probably of intestinal origin, attacks the organs draining the portal area, causing primarily a fibrosis of the spleen; and, if the toxin is sufficiently intense or the patient lives a sufficiently long time, causing a cirrhosis of the liver as well. I believe that the common association of sclerotic vascular changes in the mesenteric vessels in Banti's disease are most readily explainable on the same grounds.

Finally, in view of the fact that Banti has failed to make out a case for the disease called by his name and has not shown it to be a distinct entity, the term "Banti complex" should be substituted for the term "Banti's disease" in clinical medicine.

41 West Eighty-Third Street.

THE FRAMINGHAM HEALTH AND TUBERCULOSIS DEMONSTRATION *

D. B. ARMSTRONG, M.D., M.A., M.S.

Assistant Secretary, National Association for the Study and Prevention of Tuberculosis; Executive Officer, Framingham Community Health and Tuberculosis Demonstration

FRAMINGHAM, MASS.

As announced in the papers and elsewhere, the Framingham Community Health and Tuberculosis Demonstration is being conducted under the supervision of a committee organized by the National Association for the Study and Prevention of Tuberculosis. On this committee[1] are represented the National Tuberculosis Association, the Massachusetts State Department of Health, the United States Public Health Service, private antituberculosis organizations in Massachusetts, Connecticut, New York and Pennsylvania, and the Metropolitan Life Insurance Company, the donors of the $100,000 to be devoted to the work.

The selection of Framingham was made after several months' study of numerous communities of similar size in various parts of the United States, but particularly in Massachusetts and New York State. Framingham recommended itself to the committee because it possessed certain average qualities, being an industrial community, with mixed industries, varied racial groups, a good local health organization, backed up by an excellent state department of health, a normal amount of disease, particularly tuberculosis, well trained physicians and good hospitals, and sufficient promise of cooperation from medical, industrial, commercial and social organizations to give reasonable assurances of success.

Is it possible to discover and to place under adequate medical, nursing and relief supervision all of the cases of tuberculosis, incipient and advanced, in a normal industrial community?

Is it possible to ascertain, with some degree of definiteness, the responsible social and economic factors in disease causation, including all types of morbidity, not only tuberculosis?

What is the most efficient utilization of the existing means available for the discovery and treatment of disease? What percentage of theoretically preventable disease is practically preventable with the use of known but unused, or at least uncoordinated, instruments? What is the best possible adjustment of social forces, existing or to be created, with the objects of the prevention of unnecessary disease and death?

---

* Read before the Section on Preventive Medicine and Public Health at the Sixty-Eighth Annual Session of the American Medical Association, New York, June, 1917.

[1] The committee in charge of the work is as follows: Dr. Edward R. Baldwin, chairman; Dr. Charles J. Hatfield, secretary, and Dr. Lee K. Frankel, Mr. Homer Folks, Dr. Arthur K. Stone, Dr. Eugene R. Kelley, Dr. Steven J. Maher, Dr. William Charles White, Mr. Henry S. Dennison, Dr. Victor Safford, Dr. F. C. Smith, and Dr. Charles L. Minor.

Such, in brief, are the fairly ambitious questions which Framingham is attempting to solve. If the community is the logical social unit for disease prevention and control, and if the time is right for the application of a complete program for disease prevention and health creation, there is every reason to hope that, in some degree at least, answers to the foregoing questions may be demonstrated. Obviously, the roblem is not only one of tuberculosis and not only ealth problem. Fundamentally it is a problem of ial and economic organization.

As indicated above, the objects of the investigation are to demonstrate what may be possible with united community action in the problem of prevention and ontrol of tuberculosis. Inevitably, the experiment, if t goes forward as planned, will broaden out into a general health demonstration concerning itself with the various disease-prevention problems, as they affect the several age groups, and utilizing in its effort at control all potential agencies — social, industrial, educational, medical, etc.

Briefly stated, the essentials of the demonstration, as viewed by the committee, are as follows:

1. The sympathetic cooperation of all individuals and organizations, public and private, in Framingham.

2. The execution of the program on an educational, persuasive and democratic basis, social machinery being devised to carry the various elements in the community organization along with the work as it progresses.

3. The utilization of expert advisory service whenever feasible. This principle applies, of course, to general sanitary, medical, nursing, educational, school or industrial problems.

In order to present before this audience the important phases of the program within the time allowed for this discussion, special attention must be paid to the medical and health aspects of the plan, and consequently only the briefest mention can be made of other significant steps.

It will be realized by any one who has given thought to the problems of preventive medicine that the phase of a complete community program present certain theoretically clear and distinct aspects. There is, in the first place, the preparation of the community for active participation in and full understanding of the work as it is carried out. Along with this go certain activities that may be considered diagnostic in character; that is to say, there must be first a carefully designed effort to make a diagnosis of the community's vital health needs.

These diagnostic activities are further subdivided, and fall under two heads: (1) those which are concerned with the physical conditions under which the people work and live, namely, the environment; and (2) those which apply particularly to the individuals themselves.

The final step is that of community treatment, involving the application of the diagnostic findings and the following out of the therapeutic indications on a community scale. For the sake of clarity as well as brevity, I will take up in a somewhat artificial chronological order the phases of the Framingham program as they have been developed or are foreshadowed in the health demonstration.

Time will allow for little more than an itemization of these steps. Their presentation in this order is, as stated above, entirely artificial, in view of the fact that numerous activities in all phases of the work have to be initiated and urged forward simultaneously.

A. PREPARATORY STEPS

As stated previously, it is felt by the committee in charge of this work that the whole project, if it is to be of permanent value, must be carried out on a democratic educational basis. For that reason, a great deal of attention has been given to certain fundamental preliminary measures, such as the following:

1. The acquainting of the people of Framingham with the motives, methods and practical objects of the demonstration. Special literature has been distributed, almost daily articles have been supplied to the press, and numerous meetings have been addressed on all sorts of occasions, etc.

2. An intimate and elastic local committee organization. This has involved the selection of a local executive committee (of thirteen members), a local advisory council, with numerous subcommittees, a committee on infant welfare, a committee on industry, etc. In addition, and most important, plans are being made for the early organization of small informal neighborhood committees, selected on a block basis, representative of the leading personalities in the community, to serve as a direct channel of interchange between the health demonstration office and the homes of the people.

3. The encouragement of the town to meet its own obligations, and to place the nonexperimental phases of the work on a basis of permanence. This work has already resulted in the handing over to the Community Health Station of two old school buildings for possible use in the treatment of tuberculous patients, or the so-called pretuberculous children, the laying of definite plans on the part of the local hospital to meet the outpatient clinical needs of the community, the establishment of permanent, full-time medical and nursing service for the schoolchildren, the establishment of supervising nursing service by the board of health, the establishment of full-time medical and nursing service for at least half of the industrial population, provision of a full-time secretary with plans for nursing and relief service under the auspices of a local civic league, etc.

4. The organization of a local medical club. The importance of this organization cannot be overestimated, serving as it does as a channel for reaching collectively the medical men in the community. It is an instrument by which their understanding of the program may be facilitated, and the universal adoption of certain diagnostic and treatment standards encouraged.

5. The determination of tuberculosis standards. This preliminary work has been carried out by a committee of specialists from Boston and elsewhere. There have been worked out, for presentation to and use by the local medical men in Framingham, standards for the diagnosis of incipient tuberculous disease, for the diagnosis of tuberculosis among children, for the classification of recognized tuberculosis, for treatment of tuberculosis in its several stages, etc.

B. COMMUNITY DIAGNOSTIC STEPS

As stated previously, the measures aimed at the evaluation of the community's needs fall under two groups.

The first concerns *the environment.* A study of the community's disease hazards has now been completed in Framingham. This study has touched in the main the following realms of human contact:

1. An analysis of the community's statistical background. This has involved a study of death, birth and sickness statistics for the past ten years, a careful determination for different geographic and racial sections in the community of infant mortality rates, a check-up on birth registration; an effort to correct the tuberculosis death rate during the past year, etc.

2. A study of rural sanitation. One of the reasons Framingham was selected was that it presented in part of the community a distinct rural problem. The rural study covered, therefore, the hazards of rural life, involving an analysis of stable, privy, food, drinking water, housing, and other factors.

3. A study of milk production and handling, a study of food sanitation in all kinds of food shops, etc.

4. A study of general sanitary conditions in the community at large, including a privy and well census, a survey of fly and mosquito breeding conditions, and other allied problems.

5. A very careful survey of hygienic conditions in the schools, including the problems of general sanitation, cleanliness facilities, illumination, ventilation, heating, seating, etc.

6. A thorough analysis of hazards in industry, including ventilation, illumination, dust, fumes, machine guarding and facilities for cleanliness.

All of these sanitary studies have been carried out under the direction of Mr. Franz Schneider, Jr., the sanitarian for the Russell Sage Foundation, and in this work he has had the cooperation and assistance of many agencies, including the Massachusetts State Department of Health, the Massachusetts State Board of Labor and Industries, the Museum of Safety, the New York State Commission on Ventilation, and the United States Public Health Service, all of which agencies have assigned men and instruments from time to time to assist in the completion of the survey program.

The second great division of the community diagnostic problem concerns *the people* themselves. Mention has been made previously of the measures taken to ascertain the hazards of life and work in Framingham. This work has been supplemented by several distinct efforts to ascertain what actual conditions prevail among the people of Framingham, including not only factors of medical and hygienic importance, but certain indirect, yet fundamental factors, social and economic in character. A brief mention of the chief measures follows:

1. A study of infant and child life in Framingham, including particularly the preschool group. In this work we have had the cooperation of the *Delineator* magazine in its infant welfare campaign. This has made possible the visiting of every home in Framingham in which a birth was recorded during the last year, with the enumeration of certain essential prenatal, obstetric and postnatal facts. This work, coupled with an aggressive baby week campaign, has resulted in the establishment of infant clinics, on a permanent basis, involving the cooperation of the local physicians, assisted by expert consultants in difficult cases of infant morbidity.

2. A tuberculin survey of children from 1 to 7 years of age.

3. A study of physical conditions among the schoolchildren, as a part of the community's plan for full-time medical and nursing supervision of the school population.

4. A survey of social and economic conditions in Framingham, bringing out facts regarding home hygiene, income and rent, etc. This work was done in cooperation with the Massachusetts Committee on Safety, and was in reality a part of a patriotic census of resources, taken by 200 volunteer enumerators. For the most part, these enumerators were selected from their own districts, and form the nucleus for future community social organization, making possible a perpetual check on changing economic and social conditions.

5. A health or sickness canvass of rural as well as urban parts of Framingham. This work was done by nurses secured from the local hospital, as well as from cooperating Boston organizations, such as the Boston District Nursing Association. In part, also, several large insurance companies represented in Framingham, such as the Metropolitan, the John Hancock and the Prudential, aided materially in the collection of data regarding recognized and admitted illness.

Fortunately, this sickness census included those families which were later given thorough medical examinations, thereby making possible for the first time a direct comparison between sickness census findings and genuine medical examination results. In this sickness census work about 2,000 families, representing all types and conditions of people in Framingham, were covered.

6. A medical examination campaign. In this work, the most important and radical step taken thus far, about 1,000 families were first visited by nurses and insurance agents, in order to take a sickness census, and to make arrangements for medical examinations. Histories were then taken of those individuals willing to be examined, subsequent to which the people themselves, men, women and children, were given a thorough medical examination in the homes. This work involved the employment of seventy-two physicians from out of town, specially trained in tuberculosis work. It also took the full time of twenty-five nurses and eighteen laboratory workers to cover the field in one week's time.

In all, 2,400 histories were taken, 2,000 people examined, and 1,400 urinalyses made. The people examined were reasonably well distributed as to age, sex, nationality, economic condition and geographic distribution, the results being therefore representative not only of Framingham as a whole, but of any other typical American industrial community.

The final analysis of the results of this medical work is still under way, and for that reason it would be impossible, even if time permitted, to discuss the results more fully at this time. It is believed, however, that an unexpectedly large amount of suspicious and positive tuberculosis has been discovered, involving a follow-up nursing and medical program of major importance.

The committee is convinced also that the results of the work, on the general medical as well as on the tuberculosis side, will serve as a very effective instrument for the promotion of routine thorough medical examinations of supposedly healthy people.

Fortunately, the medical examinations have now become more or less endemic in Framingham, and are being carried out not only by community health station representatives, but also by local physicians. The local men are calling in expert consultants when needed, are using standard history and examination record forms, and are charging a standard price for health examinations on an individual or, preferably, on a family basis.

C. COMMUNITY TREATMENT

The foregoing measures indicate for the most part the progress to date of the Framingham Community Health and Tuberculosis Demonstration. It remains now briefly to point out what seem to the committee to be the follow-up steps, the community treatment measures, as indicated by the preliminary findings.

Obviously, there is still much to be done on the diagnostic side. A careful analysis of results thus far will indicate further measures of significance, if we are to derive from this demonstration an exact knowledge of the factors that are of importance in the production and perpetuation of tuberculosis in a normal American community.

Medical findings must be correlated with social and economic conditions. Light must be thrown, if possible, on the relative importance of infection on the one hand, and hereditary resistance on the other. Only an intensive scrutiny of the progress of the work as carried out along accepted, routine lines will indicate probable loopholes in the community's defense against disease, and probable additional measures for filling the gaps hitherto undemonstrated.

The major treatment activities immediately contemplated are as follows:

1. The correction of environmental conditions. The Community Health Station feels assured of the cooperation of local official and private agencies in the application of the findings of the sanitary study, in schools, factories, etc., or in the community at large.

2. Education and publicity. The Community Health Station will make every effort to popularize those findings which require public support for their effective application. A program of education is under construction which will reach all interests in the community, which will use not only special occasions, but also routine educational channels, such as the schools, the churches, the clubs and the factories. This work ought to lay the basis for future hygienic practices in the homes, schools, factories and workshops. It ought also to result in bringing under continuous and competent medical supervision the major part of the entire population as a result of the popularization of the medical examination finding, etc.

3. The continued encouragement of the community to meet its own obligations. This applies not only to the public requirements, such as school medical inspection, public health nursing, etc., as mentioned in an earlier part of the paper, but also such measures as medical factory inspection, improvement in dairy conditions, etc.

4. The use of the local medical organization to bring about a higher degree of efficiency and standardization in local medical diagnosis and therapeutics. An expert consultation system is being worked out. With the cooperation of the public health service, the physicians are being asked to report all types of morbidity. Standard methods for diagnosis and treatment for tuberculous cases are being advocated. Lectures and clinics bearing particularly on the detection of incipient disease are being planned under the auspices of the local medical club and the Extension Department of the Harvard Medical School, etc.

5. The coordination of nursing activities. The nursing agencies in the community, including the District Nursing Association, the local hospital training school nurses, the Civic League relief and infant welfare nurse, the school nurse, the factory nurses, and the board of health, public health and tuberculosis nurse, are also being coordinated into a nursing unit, with adequate expert supervision, emphasizing the principle of generalized rather than specialized nursing. In this work, the board of health nurse will act as the central agent, supervising the work of the other agencies on a basis of mutual understanding and cooperation.

6. Provision for outpatient medical service. The local hospital has plans for setting aside a part of its equipment sufficient to provide outpatient medical, minor surgical, infant welfare, nose and throat, eye refraction, and dental services. This work will be developed in cooperation with the local medical club, assisted by expert consultation service when necessary, and will be placed so far as possible on a self-supporting, pay, medical compensation basis. It will provide medical and health center facilities, not only for the community at large, but also for the diagnostic end of the medical services in schools and factories in the community.

7. The careful follow-up of the results of the medical examination and infant consultation campaigns, arranging for treatment by the local physicians. This follow-up work will involve certain problems not directly related to the special tuberculosis interests of the community. The groups of citizens' reports as a result of the medical examination work will be as follows:

(*a*) Normal individuals.

(*b*) Individuals with slight affections, to be referred by correspondence to their physicians for treatment.

(*c*) Individuals with nontuberculous, serious affections, to be referred by correspondence and by visiting nurses to their physicians for treatment.

(*d*) Venereal cases to be handled confidentially with the local physicians.

(*e*) Glandular cases in children, possibly tuberculous, to be reached by special nursing and educational follow up.

(*f*) Tuberculosis cases, positive or suspicious, on which the follow-up energies of the Community Health Station will be specially concentrated. This will involve nursing visits, subsequent reexaminations, treatment by local physicians, or through other channels on an expert consultation basis, final classification as to diagnosis, and continuous follow-up educational activity.

8. The use of all available treatment facilities for tuberculosis cases. This in brief involves the utilization of at least the following channels:

(*a*) Home treatment, with the aid of the local physicians, in the great majority of cases. In Framingham it will probably be possible to find the diseased individuals in the early stages of the infection, when moderate modifications in diet, personal hygiene, work, etc., will constitute adequate measures against the development of the disease. In these cases, of course, special educational and perhaps medical measures will have to be taken to prevent the spread of infection, particularly to infants and children.

(*b*) The establishment of summer camps or perhaps a preventorium for delicate children, with or without suspicious glandular development, previously known to have been exposed to the disease. For this purpose it may be possible to utilize one of the old school buildings in Framingham, held over by the town administration for this use.

(*c*) The establishment of at least a temporary and possibly a permanent local institution or clearing house for advanced cases among males and females, adults and children. This will be useful for patients on state institution waiting lists, for patients who do not desire to leave the community, or for patients whose presence at home will involve the hazardous exposure of other members of the family. Such an institution can be organized in Framingham as a distant ward of the local hospital, thereby saving considerable overhead expense in nursing and other charges.

(*d*) The local hospital has placed at the disposal of the Community Health Station a sun room for the treatment of surgical cases of the disease.

(*e*) Wherever possible, established treatment facilities for advanced cases, or for incipient cases likely to be improved by out of town treatment, will be used. This includes the four Massachusetts state institutions, several neighboring private hospitals, a large county hospital now under construction, etc.

9. Continued hygienic education. This, of course, is an ever present need in any community, and will be carried out continuously through all regular and special channels, reaching school, factory and other groups. This public health educational work will for the most part be under the permanent supervision of an established local organization, namely, the Civic League. An effort will be made to bring under this organization all private agencies interested in health or preventive medical work, thereby coordinating and centralizing efforts along these lines.

10. The coordination and permanence of local health and relief activities. As stated in the beginning, one of the essentials of the program is to have perpetuated on a permanent basis those activities which are demonstrated to be of continuous value to the community.

There exist in Framingham two agencies for this work: (1) the board of health, which, with the assistance of the other official branches of the town government, is being encouraged to meet the normal community needs along public lines, and (2) the local Civic League, which organization is equipping itself to carry on health educational work, to promote domestic science and home economic education in cooperation with the local public and normal schools, to coordinate and carry out on a satisfactory basis whatever relief work is necessary in the community, and in general to systematize and place on a permanent basis of efficiency those health, educational and charitable activities not recognized by the town itself as official obligations. This coordination of public and private agencies will make a permanent social organization that ought to continue to meet the community's needs along all these lines, subsequent to the experimental stages of the health demonstration. The Civic League will also give attention to recreation facilities.

SUMMARY

The methods and objects of the Framingham Community Health and Tuberculosis Demonstration are so directed as to discover disease, especially tuberculosis, in its incipiency, with the help of the local physicians, through the special examinations that have been and that are being carried on, and through the special work among infants, in schools, in factories, and elsewhere.

Adequate treatment facilities, especially for tuberculosis, will be provided as outlined above, whenever possible, on a basis of permanence, and in such a way as to require the local community to meet its own logical and natural obligations.

Finally, it is hoped that general sanitation, health education, and continuous medical supervision will act as effective instruments in the prevention of unnecessary disease and defect.

Thus far the health demonstration has demonstrated that with sympathetic cooperation from local and outside agencies, the basis for community social control over disease-producing factors can be laid. It is the hope of the committee that further developments of the work will demonstrate that on a community basis disease may be prevented and health created, thereby laying a permanent physical foundation for future social, economic and spiritual evolution.

ABSTRACT OF DISCUSSION

Dr. S. Adolphus Knopf, New York: When one desires to improve the health, vigor and morale of the community, with a view particularly to preventing the development and spread of tuberculosis, one should begin at the beginning; that is to say, with prenatal as well as postnatal care of the infant. Thus, if the mother is a working woman, she should not be allowed to work until the day before her confinement, but should be given prepuerperal care of at least two to three weeks, with instruction how to care for herself and child after birth. Breast feeding should be insisted on whenever possible. Military statistics in foreign countries prove that the breast fed candidates make better recruits than the ones who were artificially fed when babies. Unfortunately, poor working mothers are often deprived of the privilege of nursing their little ones as they should be nursed, because the few moments which can be utilized when the baby is brought to the factory do not suffice to give the child the necessary quantity of food. By and by the baby is fed artificially at home.

It seems to me in a community experiment this underfeeding of infants, particularly among the working classes, should be prevented. This neglect is, of course, equally sinful, if not more so, in the well-to-do classes who find it more convenient to have their children artificially fed. In our kindergartens the little ones often catch colds which ultimately develop into tuberculosis. In the report submitted to us by Dr. Armstrong I did not see any mention made of school luncheons. The underfed schoolchild cannot do as good work as the well fed child.

I am sorry to say that I did not see anything mentioned in the report as to the efforts made to keep the atmosphere as clear as possible. Can the doctor tell me whether they use hard coal or soft coal in Framingham.

Dr. D. B. Armstrong, Framingham, Mass.: They probably use some of both.

Dr. Maurice Fishberg, New York: It is interesting to see that at last, on a small scale, an experiment is being made to determine the real value of the methods we have been applying for twenty or thirty years and how far they have been effective in eradicating tuberculosis. Although we are now spending over $20,000,000 annually on the prophylaxis of tuberculosis, we have no exact data on which to base any method which will surely be effective. One physician tells us that everything seems all right excepting that in the inquiry the number of infants that are artificially fed should be ascertained. There is no doubt that breast feeding prevents many diseases of infancy; but 99 per cent. of my hospital patients have been breast fed, yet now they are tuberculous. We are also told that no success can be expected at Framingham unless the use of soft coal is prohibited. To be sure, smoke is a nuisance, but it does not cause tuberculosis. In Pittsburgh the tuberculosis mortality is very low and coal miners are almost immune to this disease. The work at Framingham will therefore have to be along different lines.

Too much cannot be expected in an experiment of three to five years. Tuberculous disease is not synchronous with infection, excepting during infancy. Infants, when exposed, are infected, become sick and die within a comparatively short time. But adults become sick with tuberculosis as a result of infection dating back to childhood. The adult population of Framingham has undoubtedly been infected with the tubercle bacillus long ago, and whether they will become sick with the disease depends no more on infection, but on other factors. As to what reactivates the dormant processes in the lungs remains to be determined, and the committee at Framingham has an opportunity to give us the information we are now lacking. But prophylaxis of infection should only be attempted in the case of infants.

The question of diagnosis in New York has not yet been solved. The municipal sanatorium is said to have 40 to 60 per cent. of sputum-negative cases. Now, wherever careful investigations have been made it was found that hardly over 10 per cent. of sputum-negative cases, presenting suspicious symptoms and signs of tuberculosis, are really suffering from this disease and in need of prolonged treatment. Over 10 per cent. of patients in hospitals for advanced consumptives have been found nontuberculous at necropsies. I hope that the work at Framingham will be done more by clinicians than by social workers, so that the number of nontuberculous persons treated as sick with tuberculosis will be reduced to a minimum.

I should like to warn you against judging the value of the experiment on the data supplied by the mortality rates. The tuberculosis mortality rates have been declining for over fifty years in all civilized countries; in New York, Philadelphia and Boston, for over one hundred years; while our prophylactic measures have been applied only since the last fifteen or twenty years. To be significant, the drop in the mortality rates will have to be more pronounced, the curve will have to be more steep, than it has been during the past twenty years.

Dr. Haven Emerson, New York: I have not the figures at hand as to the percentage of patients sent to the municipal sanatorium at Otisville who are positive sputum cases. The patients are mostly positive bacillus carriers, removed from homes where there are children in the household; and the others are patients who are sick enough to need sanatorium care on their own account, and are really acutely sick patients, whom any physician would wish to have put under bed care: so much so is this the case that we have found it necessary to insist on having an infirmary in which these patients can be cared for, as if in an acute hospital. What Dr. Fishberg says may have been true of the way in which the sanatorium was operated at first, when the conception of it was as a hospital for the treatment of incipient tuberculosis. The sanatorium now is operated with the idea of its being primarily to play a part in the sanitary control of the disease.

Dr. Fishberg's figures may have been based on the previous operation of the sanatorium, but I think that does not give a true impression of the character of the patients we are now admitting

---

Improvement in Retarded Children.—It is a well known fact that children who are retarded and far below the average intelligence at an early period may as they grow older catch up a year or two in mental growth. The fact that a child grades below the average by formal tests is not an infallible sign that he will never develop beyond the mental attainments of a child. An analogy is found in the retarded physical development of certain children.—Treadway, *Public Health Report,* Nov. 24, 1916.

CEREBRAL SPASTIC PARALYSIS DUE TO HEMORRHAGE

A FURTHER REPORT OF THE FIRST SIXTY-FIVE CASES OF CRANIAL DECOMPRESSION FOR SELECTED CASES *

WILLIAM SHARPE, M.D.
AND
BENJAMIN P. FARRELL, M.D.
NEW YORK

The patients were carefully selected, and only those with signs of persistent intracranial pressure were chosen, this constituting less than 25 per cent. of those examined. Ophthalmoscopic examination revealed dilated retinal veins and blurring of the optic disks; in the later cases, these findings of increased pressure have been confirmed by the measurement of the cerebrospinal fluid at lumbar puncture by the use of the spinal mercurial manometer. In all of the cases there was a history of prolonged and difficult labor, most of them being instrumental deliveries. A negative Wassermann test of both blood and spinal fluid was obtained in every case except one. No selection was made as to age, spasticity or mental deficiency. Microcephalic children, cases of agenesia (so-called Little's disease), and those due to meningo-encephalitis were naturally excluded as nonoperable, there being no increased intracranial pressure.

The pathologic condition, as found at operation and and post mortem, was noted, a written permission for necropsy having been obtained in each case. A definite fibrous cystic formation was invariably present. This lesion was supracortical in all but four cases, the others being subcortical or cortical. The cysts were punctured and their outer walls removed; fibrous formation was removed except in cases in which its removal would have caused damage to the underlying tissue; in these cases it was left alone.

After-treatment consisted in the correction of deformities by tendon lengthenings, stretching of muscles, tendon transplants, etc., massage, and careful muscle education with special attention toward establishing an improved coordination.

Of the sixty-five patients, nine died after operation, and eight have died in the past two years, making a total of seventeen deaths. We have been unable to obtain any record of four; nineteen show practically no change; twenty-five show improvement more or less marked; the youngest patient was 2½ years of age, and the oldest 17 years.

When epilepsy is a complicating factor, the prognosis is invariably bad; the immediate results were gratifying in that the convulsive seizures were less frequent, but this improvement lasted only for a few months. The younger the child, generally speaking, the more marked has been the improvement. The older the child, the less marked the improvement. In the adult cases there has been practically no improvement. Supracortical lesions are the only favorable cases; in this type damage to the nerve cells is due to pressure alone from the overlying lesion. In the cortical or subcortical lesions, there is, naturally, a definite destruction of brain tissue, and only in those cells along the edges of the cyst that are suffering from pressure can any improvement be expected.

---

* The preliminary report of this work appeared in The Journal, Feb. 6, 1915, p. 482.

* Read before the Section on Orthopedic Surgery at the Sixty-Eighth Annual Session of the American Medical Association, New York, June, 1917.

CONCLUSION

We want to make an appeal for better preventive means in avoiding this most distressing affliction. First of all, we need more care on the part of the obstetrician: careful pelvic measurements should be made as early as possible; prolonged labor should be avoided whenever possible; practitioners should realize that cesarean section is less dangerous to mother and child than is the use of the high forceps; every child should be as carefully inspected during the first few weeks of life for symptoms and signs of intracranial hemorrhage as for deformities. When these symptoms and signs are present, a cranial decompression operation should be performed as early as possible in those selected cases in which the fluid or clotted blood can be removed before any (or but little) permanent damage to the brain tissue has taken place. In this manner we believe that children suffering from this form of spastic paralysis can be reduced in number, and that the most severe cases can be avoided or improved. The essential points to be emphasized are the early diagnosis and early treatment of these selected cases.

ABSTRACT OF DISCUSSION

Dr. Fred J. Fassett, Seattle: We have, in previous times, seen promises given for the relief of such deplorable conditions, and have had good reports from the treatment up to a certain point, and there the matter has apparently dropped. I think that when it has been shown that a remedy that seemed promising at first has later become less promising, there is a tendency to drop the subject on the part of those who have introduced it, thus leaving the rest of us in the air, so to speak, as to the ultimate results. We are asked often what the final outcome was in such cases, and are compelled to answer that we do not know. We in the West have sometimes seen patients who have traveled thousands of miles to be treated in some new way, only to find out that had the later results been published, the trip would have been unnecessary. I wish, therefore, to commend the frankness with which these gentlemen have reported to us this definite conclusion of their work.

Dr. William Sharpe, New York: Dr. Farrell and I have endeavored in this report to be as conservative and as critical in regard to the results in these first sixty-five cases as one could possibly be. The point we wish to emphasize is that most of these patients over 3 years of age are derelicts, and no marked improvement can be expected in many of them. These extreme cases can be somewhat improved, but the improvement, as you see, in many of them is slight. Indeed, in only twenty-five out of our first sixty-five cases, which were of the most extreme type of the condition, can we say that the operation was justified by the results obtained.

We wish also to emphasize the fact that the cases should be diagnosed early—as soon as possible after birth—by means of careful ophthalmoscopic examinations, a measurement of the pressure of the cerebrospinal fluid at lumbar puncture by means of the spinal mercurial manometer, blood and spinal fluid Wassermann tests, etc. By selecting these patients carefully and operating only on the ones with increased intracranial pressure can we expect to obtain definite results. I have now operated on nine of these infants on the day after birth, with excellent results. Only about one out of every five patients examined has shown signs of increased intracranial pressure, and naturally only these selected patients were operated on.

I wish also to emphasize the importance of getting permission for necropsy in this work. Of the 282 children I have now operated on out of almost 1,400 children examined, we have had permission for necropsy in every case before the operation, and of the twenty-eight children who died we found the intracranial hemorrhage in all but one of them. In the early cases we can get excellent results; but in the wrecks or derelicts of several years' duration, very little can be expected in the way of a marked improvement.

THE IMPORTANCE OF THE LIGAMENTS OF THE ANKLE IN CORRECTION OF CONGENITAL CLUBFOOT *

ISADORE ZADEK, M.D.
AND
E. L. BARNETT, M.D.
NEW YORK

It is generally conceded that the best time to begin treatment in cases of congenital clubfoot is within a few weeks after birth.

The usual procedure is to correct the varus by means of manual force, gradually overcoming the deformity and maintaining by means of plaster of Paris the correction obtained each time. When the varus has been overcome completely, and the foot is overcorrected and in eversion, the equinus is attacked. A similar method is followed here, using plaster of Paris, braces, or adhesive tape, to maintain the amount of correction obtained. This suffices in a large percentage of cases to effect an anatomic restoration of the affected structures of the foot. However, this leaves a large percentage still uncorrected.

Fig. 1.—After achillotomy; patient aged 5½ years; foot pushed up as far as possible; no change.

It is with the element of equinus that we have been chiefly concerned. Observation of a considerable number of so-called cured congenital clubfeet treated by manipulation shows the varus practically overcome, while the child stands and walks without being able to put his heel squarely on the ground.

A properly cured case of congenital clubfoot treated by one of the usual methods in vogue, employing only manual force, shows at the end of treatment a considerable degree of dorsal flexion of the foot. When the foot goes into dorsal flexion it goes as a whole, so that the plantar surface is in one plane.

---

* From the clinic of the Hospital for the Ruptured and Crippled.

* Read before the Orthopedic Section of the New York Academy of Medicine, May 18, 1917.

In many cases results are not so fortunate. In these unsucessful cases the foot can be pushed up almost to a right angle with the sole in one plane, but when further correction is attempted we get a sole with a generally rounded contour. This means that the malposition of the os calcis and astragalus has not been rectified. In these cases we have made our correction in the front half of the foot at the mediotarsal and subastragaloid joints, and we have broken up the normal relations of the bones of the foot, producing an parently overcorrected-noncorrected equinus." The vitable result is that this overcorrected part of the foot later drops to a position relatively normal as regards the posterior half of the foot. We then have a so-called "relapsed clubfoot," which term is a misnomer.

At this stage, one finds dorsal flexion of the foot *restricted, and the resistant structures show no elasticity* and hence no give under steady pressure of extreme force. The obstacle shows so little tendency to yield that one might readily conclude that it was bony.

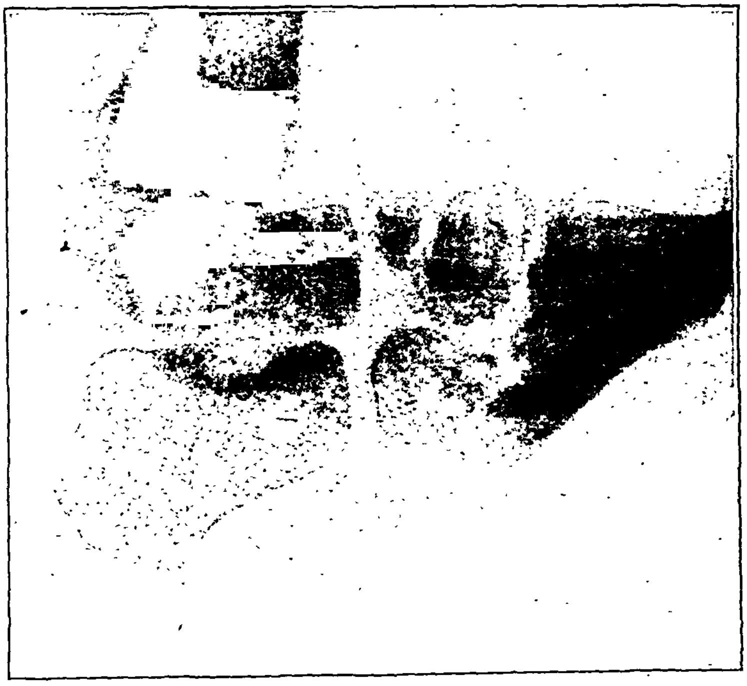

Fig. 2.—Following achillotomy; same patient; posterior ligaments of ankle were cut subcutaneously; now foot can be pushed into dorsal flexion, and os calcis tilts up to normal degree.

Health Report,

We have followed by means of the Roentgen ray the relative effect of section of the Achilles tendon and the posterior ligaments of the ankle joint, as regards the freedom of dorsal flexion of the foot immediately afterward and the positions assumed by the os calcis (Figs. 1 and 2).

We were unaware of the ease with which the posterior ligaments of the ankle can be cut subcutaneously, and our first case was done under the fluoroscope.

The technic which we have employed has been to use a tenotomy knife with a long shank and small blade with a cutting edge only on one side. The knife is inserted on the inner side of the ankle just at the inner edge of the Achilles tendon, and on a level with the tip of the internal malleolus. The back of the blade is turned inward. After penetrating from a quarter to half an inch, depending on the age of the patient, the blade is turned so as to lift the vessels, nerves, and other structures up on its back, and the blade is pushed deeper. Maintaining this position, the blade is swept outward from the internal malleolus while pushing up on the foot. There is an audible and palpable grating while the sawing motion is in progress. After all the resistant structures have been cut, the tenotome is withdrawn and the foot is pushed up. There is a give and sometimes an audible cracking. Now one finds the os calcis tilted up. We have thus far treated in the manner described twelve clubfeet. We would caution against using this procedure soon after manual correction has been attempted, as the foot broken and weakened at the mediotarsal joint will give at this point, and thus will not allow sufficient leverage to obtain the desired dorsal flexion of the foot as a whole.

CONCLUSIONS

1. One of us, from observation of several hundred cases of congenital clubfoot treated by the usual methods, has noted that practically none of the severe cases shows dorsal flexion to a right angle without breaking the mediotarsal joint. In view of this observation of failure to procure sufficient dorsal flexion to insure stable locomotion, this operation has been devised.

2. From a study of these cases by the Roentgen-ray, we conclude that the only reliable test for the correction of the equinus if there is a rounded sole is a roentgenogram. Many cases which have shown apparent overcorrection, when studied by the Roentgen ray show a break at the mediotarsal joint, with the malposition of the os calcis not rectified. These are the cases which later, never having had the equinus overcorrected, gradually become worse and constitute the early "relapsed clubfeet."

The Fundamentals of Military Efficiency.—Military efficiency in an individual, then, rests upon certain considerations, chief among which are health, strength and activity. To secure and keep these qualities it is essential for every man to form such habits as experience has shown to be necessary. These habits are: personal cleanliness; regulation of diet; avoidance of excesses (particularly in eating, drinking, and sexual matters); wearing suitable clothing; keeping the bodily processes at work (kidneys, bowels, skin); taking sufficient exercise, preferably in the open air; devoting a proper part of each day to rest of body and mind, with recreation for the latter; maintaining the surroundings in which one lives, in a cleanly state.—Keefer, *Military Hygiene.*

A CASE OF EPIDERMOPHYTON INFECTION OF THE SCALP*

RICHARD S. WEISS, M.D.

ST. LOUIS

The recent work of Ormsby and Mitchell[1] has revived interest in the ringworm infections of the skin.

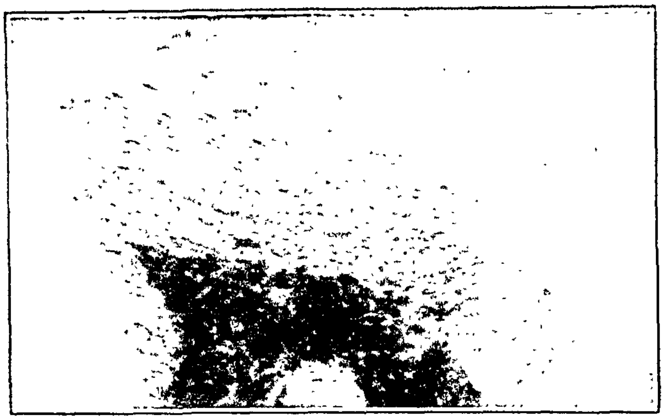

Fig. 1.—Pubic region, showing typical "eczema marginatum."

These observers call our attention to the fact that many cases of dermatitis are caused by these parasites and by one in particular, the *Epidermophyton inguinale* (Sabouraud).

A patient has recently come under observation who shows practically all distributions of epidermophyton infection, and in addition shows a new distribution, a large patch of the disease on the scalp. A careful survey of the literature which is available reveals no similar distribution, and I therefore put the case on record.

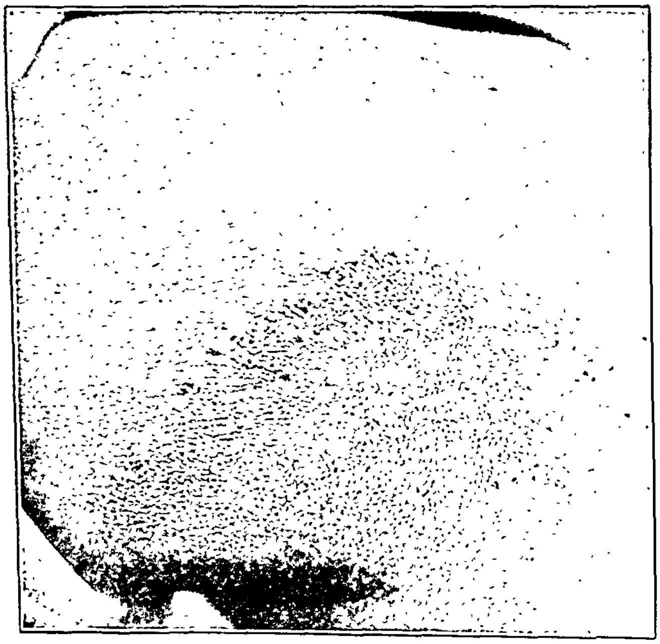

Fig. 2.—The lesion at the side of the left knee.

REPORT OF CASE

R. K., a man, aged 27, entered the Washington University Dispensary Skin Clinic, Feb. 23, 1917, complaining of "eczema." His family history and past history have no bearing on the case. He denied having had gonorrhea or syphilis. With the exception of a slight enlargement of the thyroid, the physical examination was negative.

The present illness began in November, 1915, as a few little blisters on the bottom of the right foot. It spread slowly upward between the toes and around the nails. Itching was rather severe, and there was weeping and crusting. About five months later, other patches appeared about the genitals and on the arms. These patches did not itch, but they spread rapidly. Recently patches have appeared around the left knee and on the legs. The eruption as a whole has been gradually spreading, and the itching has been getting worse. The hands were involved about a month after the disease began, blisters appearing between the fingers. These would break and a crust would form. These lesions healed spontaneously in about a month. A patch on the back of the scalp was first noticed in March, 1917.

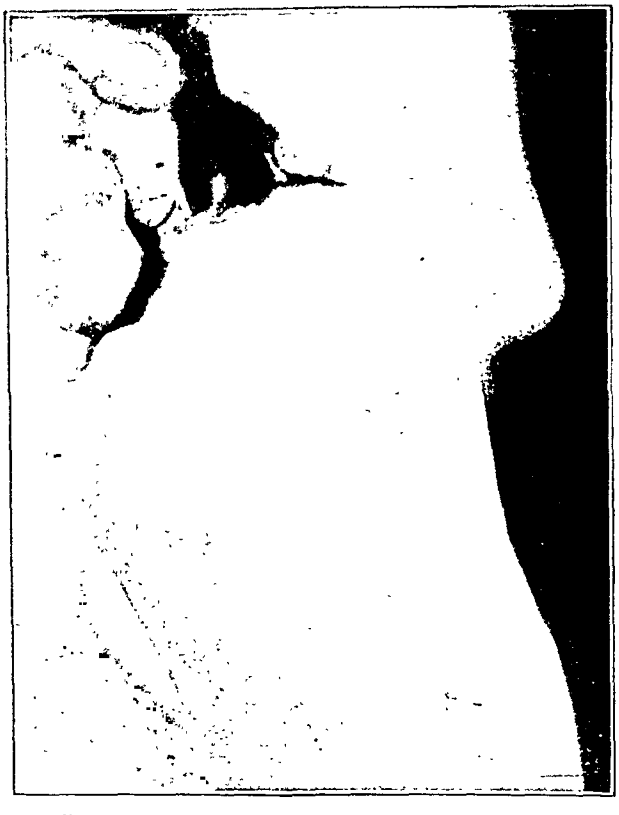

Fig. 3.—The maceration under and between the toes.

The Skin Lesions.—Distributed in various regions, the patient presents patches of characteristic dermatitis.

In the pubic, genitocrural, perineal and anal regions a typical "eczema marginatum" is found. It is of unusually extensive distribution (Fig. 1). The primary lesions are tiny vesicles and scaly papules in a typical ring arrangement, spreading at the border and clearing in the center.

On the middle third, posterior surface of the right arm, a similar patch presents itself. It has the same characteristics and is about 5 inches in diameter.

On the middle third, inner surface of the left thigh, is a similar patch about 4 inches in diameter.

Covering the internal and part of the posterior surface of the left knee another large patch is found. It is about 8 inches in its longest diameter (Fig. 2).

The right foot is also involved (Fig. 3). Beginning at the tarsometatarsal articulations and extending upward on the plantar and inner surfaces of the toes is a vesicular dermatitis with much scaling and maceration. The maceration is an especial feature between and behind the toes. Here the lesion presents undermined borders and deep maceration, and is typically characteristic of the disease in this location.

---

* From the Department of Dermatology, Washington University Medical School.

[1] Ormsby, O. S., and Mitchell, J. H.: Ringworm of Hands and Feet, The Journal A. M. A., Sept. 2, 1916, p. 711.

The back of the scalp is markedly involved (Fig. 4). The lesion takes the form of a segment of a circle, and is about 6 inches long. The advancing border consists of a ridge of scaly papules. There are no vesicles to be seen. The color is dull red somewhat masked by the hair. There is no alopecia.

The Organism.—Scrapings were made from the edge of most of the lesions, including the scalp, and fungi corresponding in type to the *Epidermophyton inguinale* were demonstrated in potassium hydroxid preparations.

Cultures were made from the edge of the scalp lesion on Sabouraud's medium and on glucose agar. Only *Staphylococcus aureus* grew in the Sabouraud tubes. On the glucose ar, *Staphylococcus aureus* appeared in a few days. About en days later, small yellowish colonies of fungi made their appearance and slowly grew until in about three weeks they were about one-half inch in diameter (Figs. 5 and 6). The color was a dirty white with a slight tinge of yellow. A week or so later the colonies were covered with fluffy, white tufts. Subcultures were made on glucose agar. The organism reproduced true to type, but the cultures were also contaminated with staphylococcus.

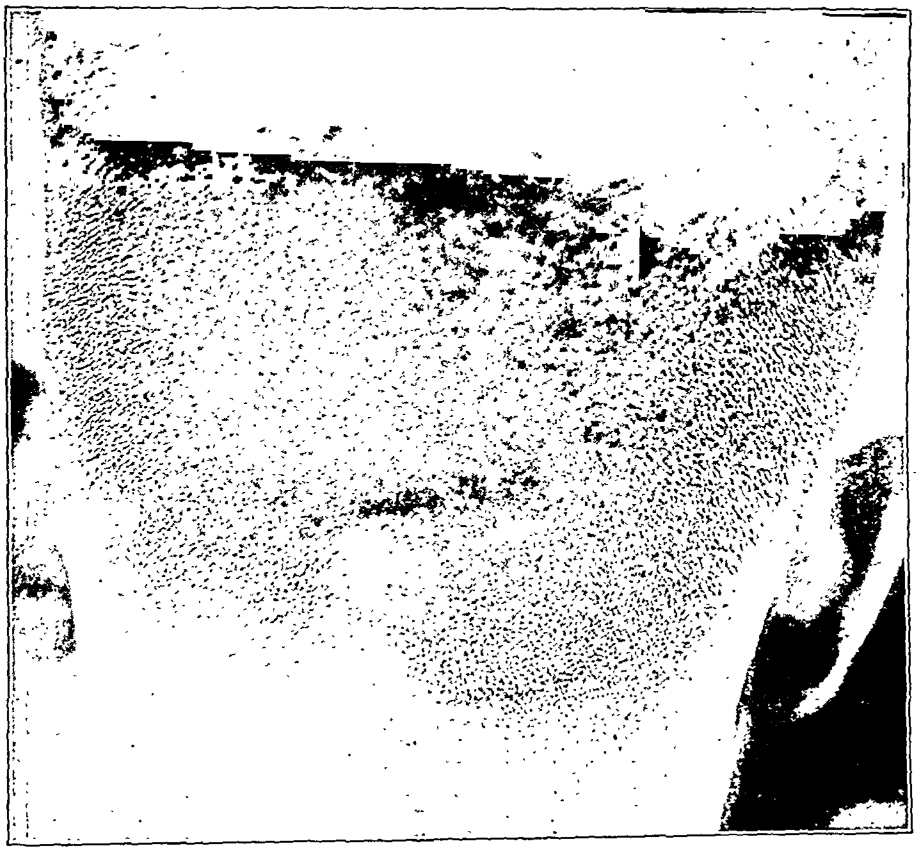

Fig. 4.—The lesion on the scalp.

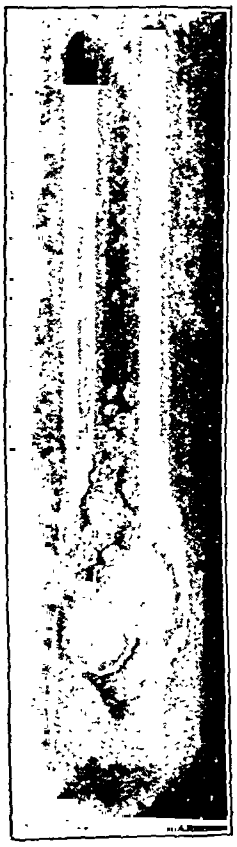

Fig. 5.—Culture of *Epidermophyton inguinale* from the scalp.

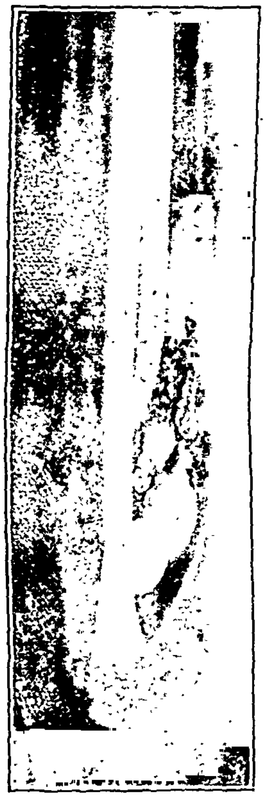

Fig. 6.—Culture of *Epidermiphyton inguinale* from the scalp.

Smears made from the cultures at about the third week showed the same organism observed in the scales from the lesions.

Hairs from the scalp lesion were examined in potassium hydroxid, but no organisms could be found.

Treatment.—The lesions were at first treated with Whitfield's ointment[2] with but little improvement. The patient was then given 3 per cent. pyrogallic acid for the scalp, pubic, crural, perineal and anal regions, and 3 per cent. chrysarobin for the remaining lesions. By May 22, 1917, the lesions had all disappeared.

COMMENT

Sabouraud[3] states that "it [the *Epidermophyton inguinale*] does not attack the hair; it requires the bottom of a flexure for its inoculation." The case described shows a lesion on the back of the scalp apparently autoinoculted from the extensive lesions elsewhere on the body. This location is not a flexure (except perhaps in very stout persons, and this patient is slender), so that it is apparent that at times inoculation may occur in places where there is no excess of heat and moisture.

TREATED AND UNTREATED OSTEOCHONDRITIS JUVENILIS OF THE HIP*

WALLACE BLANCHARD, M.D.

Fellow of the American College of Surgeons

CHICAGO

Perthes' disease, or osteochondritis juvenilis of the hip, results in far more extensive bone atrophy than has been supposed. The bone atrophy and rarefication are so extensive that they have changed our previous conception of the pathology of the disease.

Up to the present time, the only joint and bone changes recognized in Perthes' disease have been a partial or total destruction of the head of the femur with a stumping of the neck, together with a thinning of the femoral shaft. Most authors have agreed with the unsustained suggestion, made by Freiberg[1] at the last session of this Association, that the disease is caused by tonsillitis or some other local infection. Experiments have been made on animals by Allison[2] to determine what influence a slight injury or displacement to the epiphysis might have on the hip, and his results were negative.

---

* Read before the Section on Orthopedic Surgery at the Sixty-Eighth Annual Session of the American Medical Association, New York, June, 1917.

[1] Freiberg, A. H.: The Evolution of Osteochondritis Deformans Coxae Juvenilis, The Journal A. M. A., Aug. 26, 1916, p. 658.

[2] Allison, Nathaniel: Am. Jour. Orthop. Surg., October, 1915.

Since I desired to make a comparative study of diseased and normal hips, I had roentgenograms taken of cases of Perthes' disease, to include all of the pelvis as well as both the femoral shafts on single large plates. In these comprehensive pictures, I soon discovered decreased bone density and some atrophy of the pelvis on the diseased side in the acute cases.

The bone atrophy and lessened density are of about the same degree in the ilium, ischium and pubic bone as in the shaft of the femur. The atrophy of the ischium and pubic bone usually reduces the obturator foramen to one-half the size of the opposite foramen, as is well shown in Figure 4. On examining roentgenograms of both legs in one picture, it soon became apparent that all the bones of the leg suffered moderate atrophic changes. Decreased density is also seen in all the surrounding muscles and other soft parts.

The shrinking of the head of the femur leaves a vacant space in the acetabulum which shows principally adaptive changes.

Atrophy of bones and muscles is one of the first symptoms, and is as equally constant in the functionally used diseased leg as in the unused diseased leg. The atrophy becomes less as the distance increases from the hip.

Early and continued mechanical treatment that protects the head of the femur from weight-bearing, jar and concussion will usually preserve the head in its rounded shape; but observation of a number of treated and untreated cases shows that the best available mechanical treatment has little or no effect in either preventing or causing atrophy of the bones and muscles of the leg of the diseased side.

I have not been able to locate a tonsillar or other source of infection in a single case.

The moderate but extensive atrophy and decreased density of bone and adjacent tissues precludes the possibility of the disease being due to a circumscribed joint infection or an epiphyseal injury. The disease is undoubtedly trophic in character and is probably caused by an extensively disturbed blood circulation that impairs nutrition from a median pelvic line to the foot.

It is unfortunate that this rather recently discovered disease of the hip joint has been differentiated from tuberculous hip disease, with which it has been so long confused, if the treatment is to be neglected because it runs a milder course and with much less resulting deformity.

Patients who have had Perthes' disease which has been diagnosed as tuberculous hip disease, and who have promptly received the best mechanical and general treatment usually accorded to tuberculous hips, have invariably made the best possible recoveries.

The neglected and untreated cases of Perthes' disease after one or two years show the heads of the femurs to be nearly destroyed, with the necks stunted, and in coxa vara or coxa valga positions. Abduction is partly lost, and movements of the hips in other directions are slightly limited. The legs are from 1 to 3 cm. short, and the patients walk with a limp.

The friction and concussion of weight-bearing on softened bone cause the erosion of the head and the stunting of the neck of the femur. The disease is self-limited. The extensive bone atrophy, together with the obliteration of the head of the femur, runs its course in about one year, and this is followed by a longer period of bone hardening and rebuilding. One proof of this limited course is that if the head of the femur is protected from the outset of the disease by adequate mechanical treatment so that it retains its rounded shape for two years, it again becomes hard, firm and self-protecting.

Roentgenograms show a decreased density of bone in the first year of the disease, and during the second and third years the deepened shadows indicate that the diseased bones have become harder and more dense than normal bones. This hardening resembles the eburnation of soft bones after rickets, in which they frequently become as hard and firm in a child of 5 years as in a man of 25.

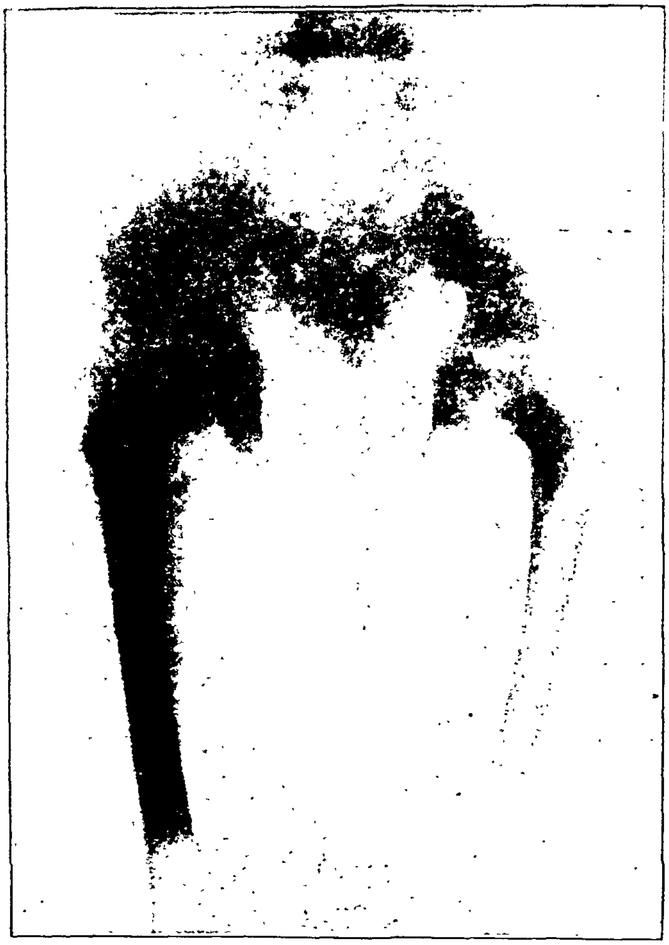

Fig. 1 (Case 1).—Atrophy and greatly reduced density of the pelvic bones, femur and muscles of the diseased side in acute Perthes' disease in a boy, aged 5 years.

There is perhaps no destructive joint lesion that is quite as amenable to treatment as Perthes' disease. The promptness with which the head of the femur rebuilds under mechanical protection is quite surprising.

If an adequate protective mechanical treatment is commenced even late in the course of the disease, when the head of the femur has been destroyed, and the treatment is then continued for a year or two, the head of the femur will regenerate to nearly its full rounded shape, in the same manner that the head of the femur rebuilds for several years after the reduction of a congenital hip dislocation, with the result that the ultimate shortening will be lessened fully a half. The limp is relieved in proportion to the regeneration of the head of the femur.

This rebuilding is a further proof that Perthes' disease is not an infective epiphysitis, since after the head of the femur has been destroyed by an epiphysitis, it does not regenerate.

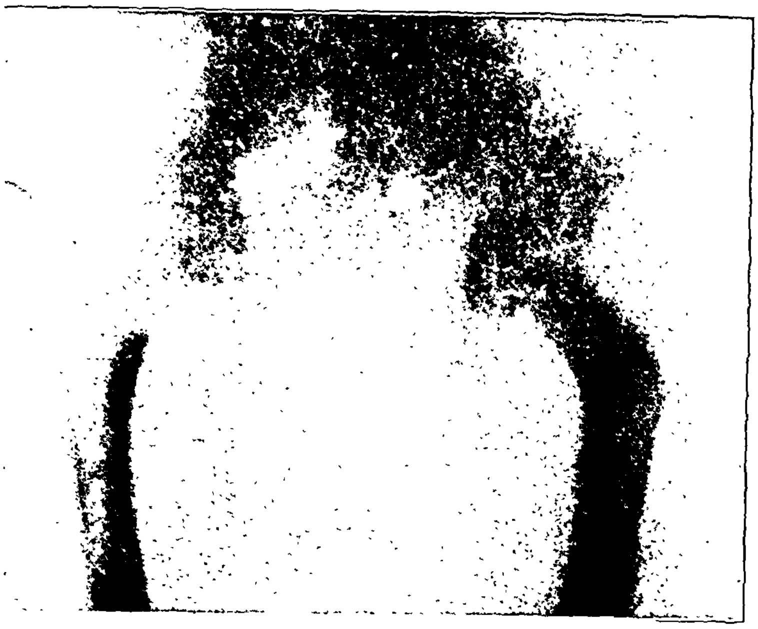

Fig. 2 (Case 2).—Reduction of the head of the femur to a small pyramid of bone in E. M., a girl, aged 8, who had had Perthes' disease for one year; the leg is 2 cm. short; the patient walks with a limp.

Roentgenograms of untreated cases of Perthes' disease, taken from seven to eight years after the disease has run its course leaving only remnants of a head or a stunted neck, show that unaided Nature has been partly successful in rebuilding the head to its normal shape.

In Perthes' disease, lengthening of the leg rarely happens, but I have one case to report.

A. H., a boy, aged 6 years, has had pain in his hip, and walked for one year with the left leg abducted. The roentgenogram (Fig. 5) shows the usual atrophic changes. The abduction leverage on the softened neck and shaft of the femur during the one year of acute disease has straightened the normal outcurve of the shaft and elevated the neck about 35 degrees, causing a 4 cm. lengthening of the left leg. The abduction protected the head of the femur, which shows only atrophic changes. The hardening stage is somewhat advanced, and nothing but an osteotomy at the neck can restore the normal relations. The boy walks with a limp to the right.

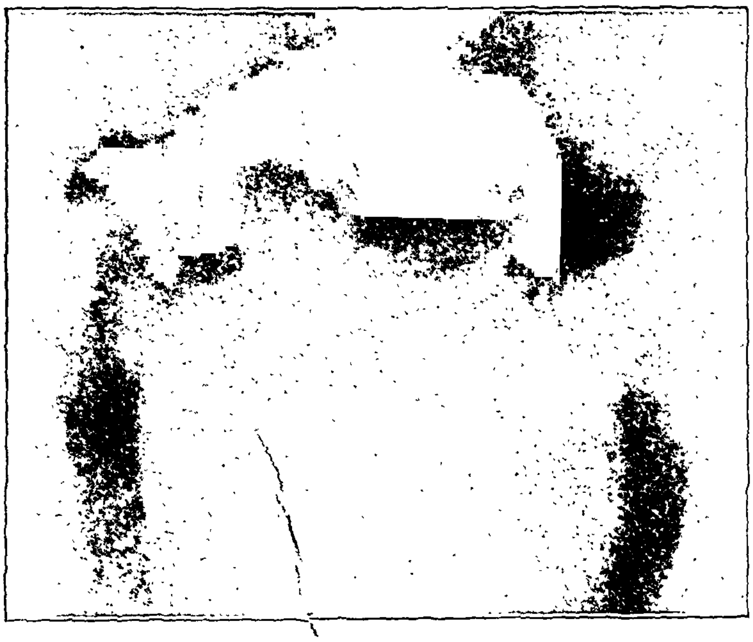

Fig. 3 (Case 2).—Regenerated head of the femur in E. M. at the age of 15 years; the patient had mechanical treatment during the second year of the disease, and walks without a limp.

In marked contrast to the depression seen in tuberculous hip disease, patients with Perthes' disease usually retain the irrepressible spirits of healthy childhood.

In going over thirty years of hospital and private histories of tuberculous hip disease, I have been able to cull out over forty cases of undoubted Perthes' disease in which the patients were treated as having tuberculous hips and discharged cured with results too suspiciously good to have been obtained in tuberculous cases. In a number of these cases, the roentgenograms confirm the late diagnosis of Perthes' disease. It is a consolation to know that even if the diagnosis was incorrect the patient received the best possible treatment.

The condition is not likely to be confused with any other than tuberculous hip disease. The patient is usually from 4 to 10 years of age, walks with a slight limp, and complains of occasional pain. There is always some atrophy of the thigh and less of the leg. Abduction is limited, but movements in all other directions are free. These symptoms closely resemble the symptoms of an insidiously advancing tuberculosis of the hip joint, but the roentgenogram will usually decide. If it is too early for pathologic conditions to show decisively in the roentgenogram, one should be taken a month or several months later, but the mechanical treatment should be begun immediately, since in either condition the treatment will be the same, and the treatment cannot be commenced too early. With the hip joint well protected, constant exercise in the open air and a liberal raw food diet seem to be of greatest service in the treatment of Perthes' disease.

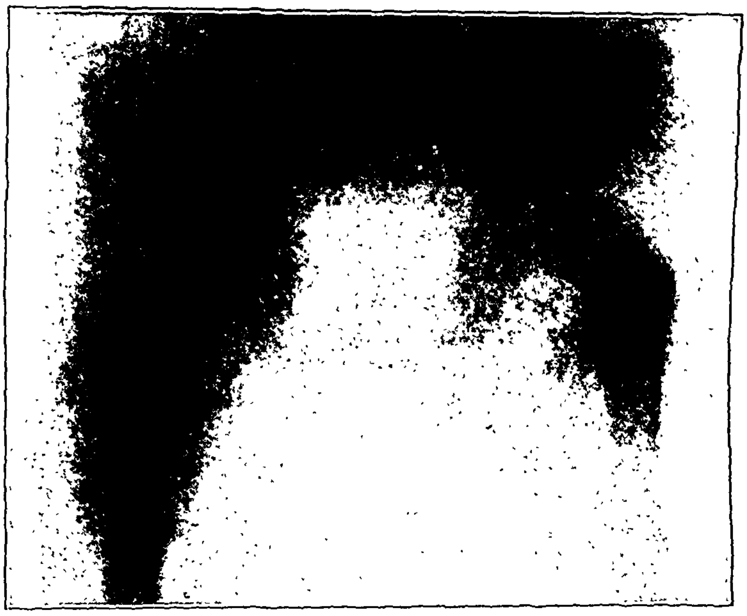

Fig. 4 (Case 3).—Head of the femur, in which only two small buttons are left, in an untreated case of Perthes' disease in a girl, aged 8 years; the leg is 2.5 cm. short, and the patient walks with a limp.

Every orthopedic surgeon is familiar with the plaster-of-Paris spica and with a variety of hip splints that afford good protection to the head of the femur, and I present the accompanying pictures of patients with Perthes' disease, the one in a plaster-of-Paris spica and the other in my strap iron hip splint with high shoe and crutches, only to emphasize the necessity of very complete protection to the hip joint in order to get the best possible ultimate results.

CONCLUSIONS

1. Osteochondritis deformans juvenilis seems to be a nutritional disease of the bones and muscles of the hip and leg.

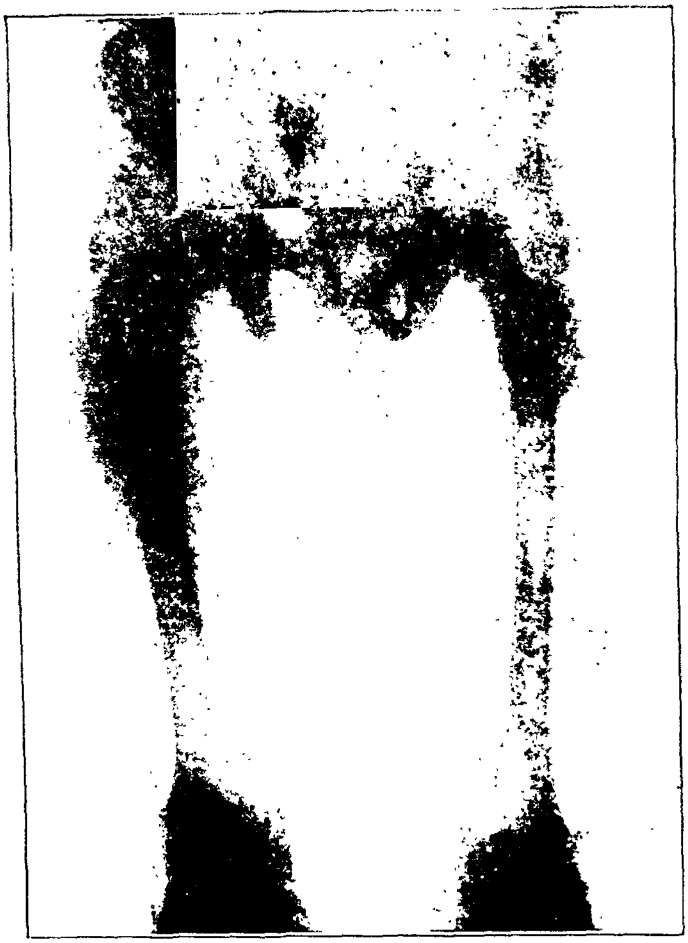

Fig. 5 (Case 4).—Lengthening of the leg in Perthes' disease, a rare resulting deformity, in a boy, aged 6.

2. The femoral head that continues in functional use during the acute stage of the disease becomes obliterated wholly or in part by the attrition of weight-bearing on softened bone.

3. The head of the femur that is mechanically protected throughout the acute stage of the disease suffers only the same atrophic changes as the adjacent bones.

4. In convalescence, the destroyed head redevelops rapidly under mechanical protection, and redevelops more slowly and less perfectly without protection.

5. The disease progresses with one year of bone and muscle atrophy and lessened density followed by several years of increasing density and redevelopment.

6. The bone hardening resembles the eburnation after rickets.

7. From the foregoing facts it may be inferred that this disease of growing bone is nutritional character, and is due to a blood circulation that is disturbed from a median pelvic line to the foot, and that the head and neck of the femur are only incidentally affected.

8. The question of etiology remains of chief interest.

15 East Washington Street.

ABSTRACT OF DISCUSSION

Dr. John Joseph Nutt, New York: Although the author of the paper said that the etiologic factors are of the most interest, it seems to me that it is of more practical interest to decide on the best method of treatment. A great many advocate treating these patients not at all; some advocate treating them slightly; and some advocate treating them much more thoroughly. If we treat them too slightly and neglect them, I think we will have worse results than by making mistakes in diagnosis and treating them as tuberculous hips.

One point that I have never thought of before is that as the head becomes flattened and lessened, the line formed by the lower edge of the shadow of the neck does not quite fall in line with the line showing the upper border of the obturator foramen.

Dr. Percy W. Roberts, New York: I merely wish to ask Dr. Blanchard what, in his experience, have been the acute symptoms; or, perhaps, to put it differently, in what proportion of cases has he seen such symptoms as pain and spasm?

Dr. Frederick J. Gaenslen, Milwaukee, Wis.: I want to emphasize what I consider a very important point made by Dr. Blanchard. The tendency has been to let these patients go on about as they pleased, feeling that ultimate recovery, with but slight deformity, would result. I think he has sounded an important note of warning in advising against this, and I endorse his recommendation of judicious supportive treatment.

I wonder whether Dr. Blanchard did not make a mistake in referring to Dr. Freiberg as having written a paper on the infectious origin of osteochondritis. I think it was Dr. Kidner.

I became much interested in this condition when Calvé, in 1912, at Berc-sur-mer, showed me some cases of what we now know as Perthes' disease, which he described as pseudocoxalgia. When I visited Perthes at Tübingen in the same summer he showed me examples of the same group of cases. I told him at that time that it corresponded exactly to the type of cases that Calvé had shown me. He was much interested, and I let him have the reprint that Calvé had given me. At first he thought the cases were not the same; but later changed his opinion, and regarded them as identical. If we want to add another name to the already hyphenated appellation of the disease, I think the name of Calvé should find a place in it.

Dr. Samuel C. Baldwin, Salt Lake City: I did not hear Dr. Blanchard say anything about the symptoms, or whether in his cases he found much pain. Last year, at the clinical meeting of the American Orthopedic Association at Philadelphia, Dr. James K. Young showed roentgenograms of several cases in which there had been a great deal of destruction of the bone. I have had one very interesting case recently, which illustrated what Dr. Blanchard has said about these cases having been treated for tuberculous hip disease, years back, when they were real cases of Perthes' disease.

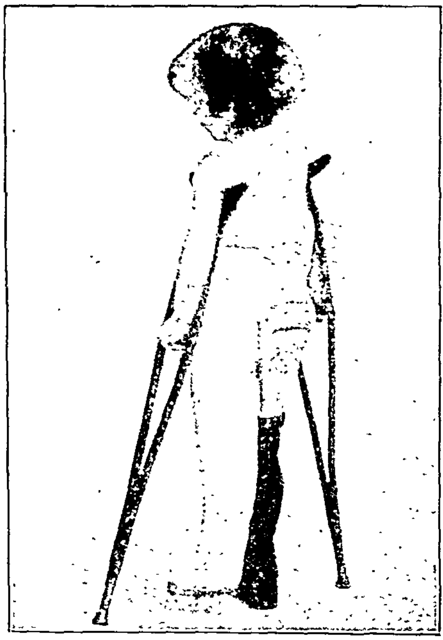

Fig. 6 (Case 5).—A girl, aged 5 years, with Perthes' disease, in a plaster-of-Paris spica with high shoe and crutches.

About fifteen years ago, I had a boy whom I treated for hip disease. Last summer his sister was brought to me with a condition that looked exactly like Perthes' disease of the

This rebuilding is a further proof that Perthes' disease is not an infective epiphysitis, since after the head of the femur has been destroyed by an epiphysitis, it does not regenerate.

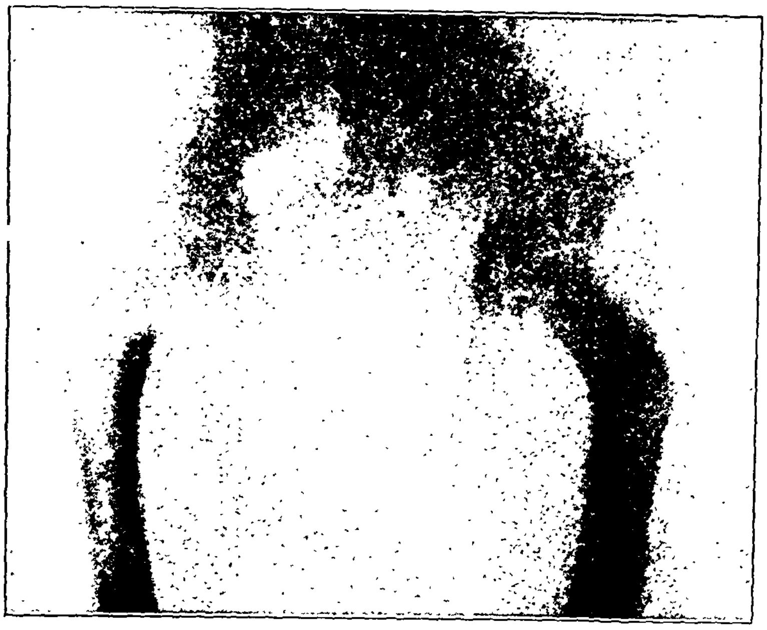

Fig. 2 (Case 2).—Reduction of the head of the femur to a small pyramid of bone in E. M., a girl, aged 8, who had had Perthes' disease for one year; the leg is 2 cm. short; the patient walks with a limp.

With the hip joint well protected, constant exercise in the open air and a liberal raw food diet seem to be of greatest service in the treatment of Perthes' disease.

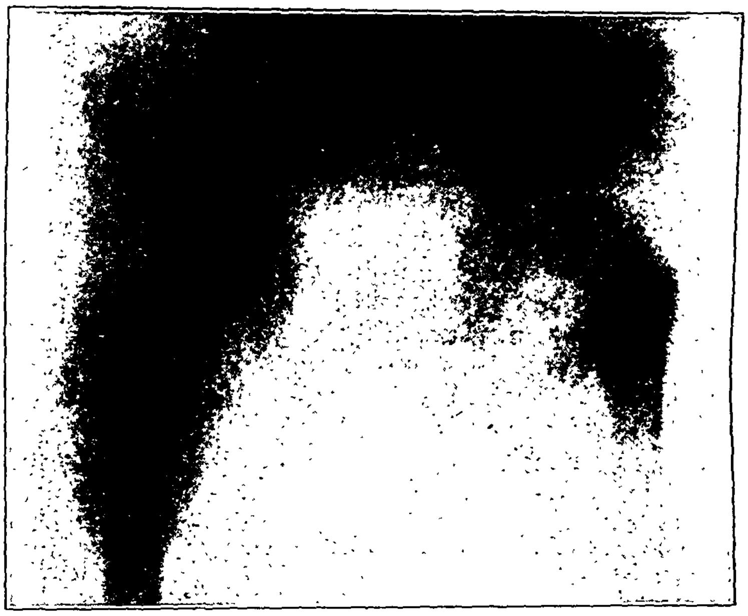

Fig. 4 (Case 3).—Head of the femur, in which only two small buttons are left, in an untreated case of Perthes' disease in a girl, aged 8 years; the leg is 2.5 cm. short, and the patient walks with a limp.

Every orthopedic surgeon is familiar with the plaster-of-Paris spica and with a variety of hip splints that afford good protection to the head of the femur, and I present the accompanying pictures of patients with Perthes' disease, the one in a plaster-of-Paris spica and the other in my strap iron hip splint with high shoe and crutches, only to emphasize the necessity of very complete protection to the hip joint in order to get the best possible ultimate results.

Magendie,[2] Luschka,[3] Falkenheim and Naunyn,[4] Sicard,[5] Meek,[6] Mestrezat,[7] Cathelin[8] and others ought, however, to leave no doubt on the question. Cushing[9] accepts as true that the choroid plexus is the chief source of supply, but states that "this has not been conclusively proved." The ependyma cells probably add a small quantity of liquid.

How and where does this secretion leave the subarachnoid space? The responses to this question are less satisfactory than are those respecting its formation. The once much discussed pacchionian theory is not tenable. It has been held that the fluid escapes along the cranial and spinal nerve roots and blood vessels, all of which have projections from the leptomeninges. Weed[10] states that fluid escapes by way of the villi in the subarachnoid space and thence into the lymph and venous channels.

The cerebrospinal fluid differs from all other human secretions. It is conclusively not a transudate. It is not lymph. The secretion resembles rather closely the fluids found within the eyeball and the internal auditory organs.

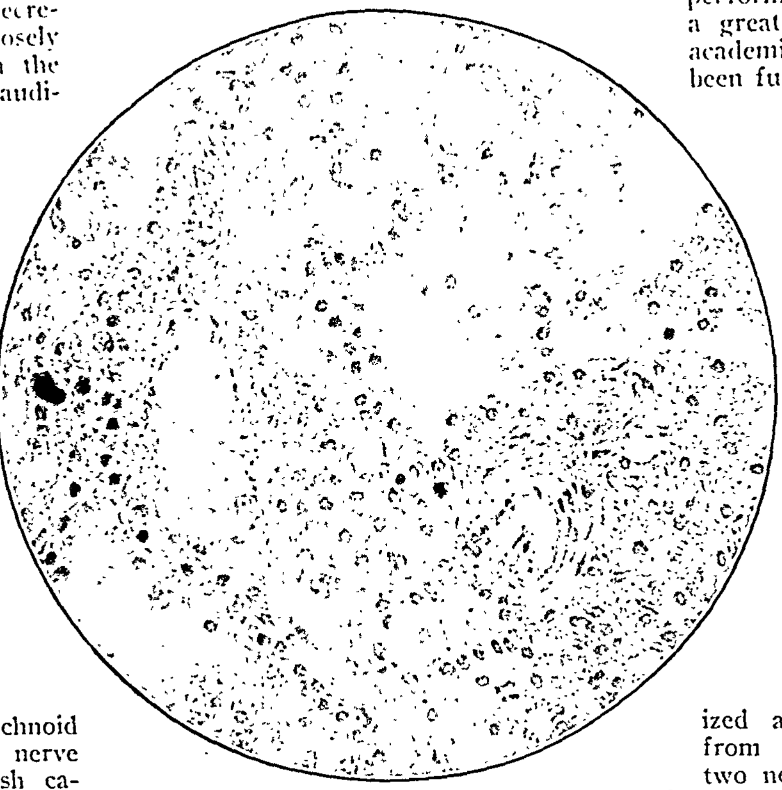

Fig. 2.—High power magnification of an area of choroid plexus gland in case reported, showing normal and pathologic choroid cells.

Is there a circulation? There does not seem to be any clearly systematic and continuous flow of the spinal fluid from one area of the ventricle or subarachnoid space to another. However, ample proof is at hand to show that there are movements. Sicard and Cestan[11] injected India ink into the subarachnoid space in the atlanto-occipital region, and found a rather rapid distribution of the carbon particles in the culdesacs, the subarachnoid areas and around the nerve roots. Dogs and fresh cadavers were used for these experiments. Later others have demonstrated a circulation of the fluid with movements directed caudad and cephalad. I am inclined to look on these movements, which constitute the circulation, as coming from transmitted energy having its source in the cardiac and respiratory acts. Oscillations from both can be seen at every normal spinal puncture. Luschka demonstrated a lining of cilia on the projecting surface of the ependyma cells. Others have described a similar structure. These cilia may be a factor in the circulation.

Quincke,[12] in 1872, while working in a physiologic laboratory, reported some experimental cerebrospinal fluid work on animals with reference to pressure. Nineteen years later Quincke[13] published reports on the first lumbar punctures performed in pathologic human cases, which included thirty adults and twelve children. A description of his manometer appears. This consists of a needle with its mandarin, rubber connector, a glass tube and a measuring stick with millimeter graduations. For some years following Quincke's reports there was a slow addition to our experimental knowledge and a comparatively small number of lumbar punctures performed for diagnostic and therapeutic purposes. During the past ten years, a rapid increment in the number of lumbar punctures performed has been noted, and a greatly increased fund of academic and clinical data has been furnished us along physical, chemical and biologic lines.

A number of manometers have been presented to the profession, mostly for water readings. The few mercury apparatus are not as practical. The water readings may be converted into mercury by dividing with 13.6. The two-way and three-way needles are convenient, but they rust and early give trouble.

I use an apparatus[14] of my own design (Fig. 1). It is simple, easily sterilized and readily kept free from rust. It consists of two needles of different size and strength, a short rubber connector and glass manometer tubes. The stylet should be withdrawn from the needle before puncturing. First one connects the first glass manometer tube into the connector (*c* and *d*). Then, the flow being established, the connector is immediately applied (*c* into *b*). If the pressure is abnormally high, the other glass tubes which have ground ends may be used to make a longer vertical column. They have millimeter graduations. The outer end of the needle (*b*) is ground so that a syringe of Lüer type can be adapted. The rapidity of flow can be controlled by the stylet. When the flow comes from the needle in a stream or dropping rapidly, it should be checked partially with the stylet. When fluid is drained off too rapidily, there is more danger of postoperative headaches or disagreeable head symptoms, which often continue for some days. In intracranial lesions with greatly increased pressures, especially tumors located in the posterior fossa, too sudden withdrawal of the spinal fluid might produce alarming symptoms. The literature contains reports of a few deaths resulting from lumbar punctures performed on patients having a tumor in the posterior cranial fossa.

[14] Obtained from the Physicians' Supply Co., Kansas City, Mo.

It might be contended that a manometer for accurately measuring the spinal fluid pressure is not necessary for practical purposes. I cannot agree to such a contention if careful spinal fluid work is to be considered. Recorded figures for pressure have much diagnostic value for a number of organic diseases within the cranial and spinal cavities. The number of drops per minute, or stream volume, can furnish only a very crude estimate of the pressure. Often, too, such a method leads to gross error. A cauda equina root in the lumbosacral cistern, or arachnoid tissue, might almost stop the flow; but if a manometer be applied, a pressure of several hundred millimeters will be found. The medulla may be pressed down into the foramen magnum, allowing only a small number of drops per minute, while if the manometer is used a high pressure reading might be obtained. When the spinal fluid is removed simply for therapeutic reasons, it is important to take a reading from time to time during the puncture.

The normal spinal fluid pressure as measured by a manometer at the lumbar region is subject to variations. The reason for some of these variations has not been explained satisfactorily.

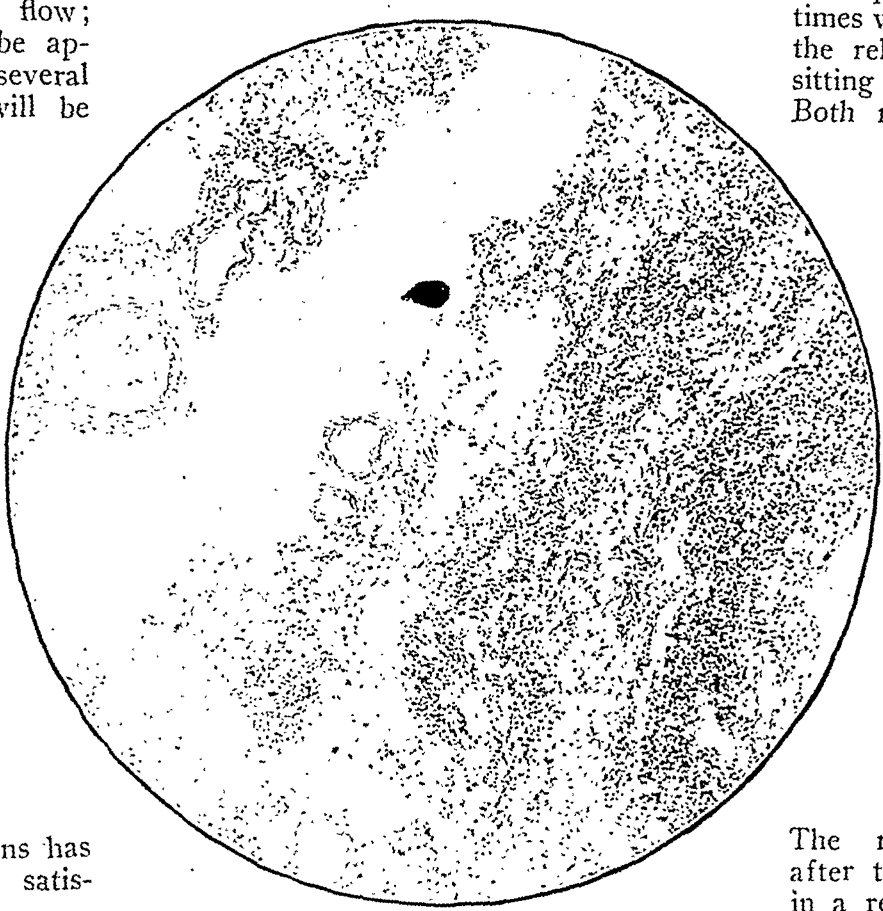

Fig. 3.—Low power magnification of an area of choroid plexus gland in case reported. The villi and choroid cells have been destroyed completely. Some vascular infiltration is seen. Massive round cell infiltrations are much in evidence.

I find that the normal pressure in the normal person taken in the sitting posture with head bent forward ranges from 90 to 150 mm. of water. In searching the literature we find a wide range of differences for the normal pressure. There is evidence in some reports that pathologic cases were used to find so-called normal pressures. As far as possible, especially if one is not doing frequent lumbar punctures, the patient should be placed always in about the same posture.

Whether the head is bent forward or held erect occasionally influences the reading a few millimeters. Cardiac and respiratory oscillations are always observed, the latter being greater than the first and ranging from 10 to 20 mm. Coughing and physical strains may produce a sharp increase in the pressure.

Why do we have this subarachnoid pressure, and whence is the energy derived? Hydrostatic pressure accounts for possibly a small portion. The blood vessels and transmitted heart muscle energy cannot account directly for it; at least only slightly. High blood pressure does not cause an increased cerebrospinal fluid pressure. The elasticity of the leptomeningeal tissues seems to account for a portion. Closely associated with this is capillarity. The choroid plexus gland, or its secretion, is responsible for the largest percentage of the pressure. In most of the places the subarachnoid cavity has walls comparatively closely coapted. Pfaundler[15] names the following four component factors in normal cerebrospinal pressure: (1) *compression pressure, contained within the fluid itself*; (2) hydrostatic pressure; (3) pressure transmitted from the blood, and (4) *elastic pressure, deriving its energy from the elastic subarachnoid walls.* The last seems to be the most important. The portion described by Pfaundler as compression pressure should not be considered separately. It is a result of the other three.

I have performed lumbar punctures a number of times with a view to obtaining the relative pressures in the sitting and reclining postures. Both normal and pathologic material has been used. After the pressure has been read in the sitting posture, the patient is placed in a reclining position, leaving the head on a level with the point of entrance of the needle, which has remained in the canal during the change of posture. In the majority of cases the pressure remained about the same both for the normal and pathologic cases. In one case of chronic serous meningitis, the pressure at the start was 270 mm. of water in a sitting posture. The registration was 190 after the patient was placed in a reclining position. The pressure returned promptly to 270 when the patient was restored to the initial sitting posture.

A great number of pathologic states involving the brain, spinal cord, and their membranes will produce alterations of tension of the subarachnoid fluid. States with increased pressure exceed tremendously those with decreased pressure.

In my experience, brain tumor cases have furnished the highest pressures, often registering from 620 to 700 mm. and more. There have been reported pressures reaching 1,000 mm., but these are rarely encountered. Much caution should be exercised in lowering the pressure when high figures are registered.

Tuberculous meningitis gives an exceptionally high pressure, but does not reach that of the tumors. All forms of syphilis of the central nervous system, including tabes and general paresis, furnish high pressures ranging from 250 to 400 mm. Paresis and secondary or tertiary meningitis supply the higher figures.

---

[15] Pflaundler: Ueber Lumbalpunktionen an Kindern, Jahrb. f. Kinderh., 1899, 49, 264.

Hydrocephalus, if the intracranial pressure has not prevented an outflow, causes a greatly increased spinal fluid tension. In a number of the chronic degenerative neural diseases there are moderately increased pressures.

All the acute meningitis cases will show a sharp rise in the spinal fluid pressure. Acute poliomyelitis, rabies, tetanus, several intoxications and alcoholic delirium furnish somewhat increased pressures, usually about 200 to 300 mm.

Head traumas and particularly brain hemorrhages will provoke a considerable increase in the spinal pressure.

The most frequent causes for real, pathologically low pressures are inflammations of the spinal cord preventing patency of the subarachnoid space and the flow of fluid to the lumbosacral cistern. A spinal cord neoplasm or cyst may cause a similar condition. When a tumor of sufficient size is pressing on the cord, the manometer may show only a few millimeters' pressure (about 20 to 40 mm.). After the removal of from 1 to 5 c.c. of the spinal fluid by lumbar puncture, this low pressure promptly drops to nil.

The following is an abstract of a case report with low pressure:

> A man, aged 57, concerning whose family and personal history no data were obtainable, but who was admittedly an alcoholic, complained of weakness, headache and a general decline. There was much mental torpor. The pupils were sluggish to light and irregular. All deep reflexes were mildly increased.
>
> A necropsy held twelve hours after death revealed changes of a specific nature throughout the cardiovascular system. The dura was much adherent to the leptomeninges. The pia-arachnoid was denser than normal and had numerous whitish plaques scattered about.
>
> The brain was rather wet. The choroid plexus could be traced through all the ventricles, but everywhere was more or less excessively adherent. The villi could not be separated, as can be done in the normal brain. The choroid cells were, to a great extent, completely destroyed. In some large areas not a single cell was visible. Among the villi best preserved there could always be found some cells degenerated, or even destroyed. In case all the cells had been destroyed, there remained stubs of villi, and more or less agglutinated masses. These masses contained dense connective or cicatricial tissue.
>
> Specific infiltrations with large masses of round cells were nicely illustrated. These gummatous masses were irregularly distributed, but were most numerous and largest in the areas in which the destructive process was more complete.
>
> The arteries, especially the smaller arterioles, frequently had thickened walls. Often the walls were considerably thicker in one area of the vessel than in another.

Rachiocentesis is customarily performed at the third or fourth lumbar spaces, hence the term "lumbar puncture." However, there are a few instances in which it can be performed to greater advantage in one of the dorsal or cervical spaces. As an illustration, in a case of tetanus I have successfully injected antitoxin into the subarachnoid space between the upper dorsal vertebrae. The lumbar region was so arched and rigid that no needle could enter its spaces. Also when a transverse cord lesion exists I have employed dorsal and cervical punctures in order to demonstrate the difference in pressure in the lumbar region and in the region above, which contained a tumor, cyst or other possible compressing material. The fluid collected from above and below certain lesions has often physical and chemical differences of much diagnostic significance.

SUMMARY

The abstracted case report contained herewith demonstrates that impaired function or destruction of the choroid plexus gives a diminished quantity of cerebrospinal fluid and a lowered pressure, as shown by rachiocentesis. This supports the contention that at least the bulk of the cerebrospinal fluid is secreted by the choroid plexus cells.

There exists a definite spinal fluid pressure which has certain variations according to various observations. A minimum figure can be placed at 90 and a maximum at 150 mm. (water manometer). When pathologic states exist, high pressures greatly preponderate. It is more difficult to be assured of the reality of a low pressure, but its presence has much diagnostic weight.

Accurate registration of the subarachnoid fluid tension within the entire craniospinal cavity should be more generally recorded, for comparative pressures have a great deal of diagnostic value in many neurologic diseases.

ABSTRACT OF DISCUSSION

Dr. William M. Leszynsky, New York: I should like to introduce a word of caution in regard to the possible breaking of the needle in lumbar puncture, which has occurred in many instances. The ordinary steel needle should not be used. Lately a needle has been made according to my suggestion, called a nickeloid needle, which is noncorrosive and can be bent at a right angle, so that under ordinary usage breakage is practically impossible.

Dr. A. L. Skoog, Kansas City, Mo.: I broke one needle in puncturing the skin. When I started doing lumbar punctures I experimented on cadavers. I broke one needle on the cadaver. It was an iridium-platinum needle, and I have never used one since. All the needles which I use are tested at intervals. It is wise to be careful with the needles. It is important to know the pressure of the cerebrospinal fluid, and one cannot always tell this by the rapidity of the dropping. If there is a greatly increased pressure patients are more likely to have severe headaches. I would give a word of warning about suddenly reducing a very high pressure of the cerebrospinal fluid to normal; for instance, in the case of tumor in the posterior fossa. One must be very careful. A number of deaths have resulted from sudden reduction of tension in tumors of the cerebellum and that region.

Common Colds.—The phrase "common colds," like "charity," covers a multitude of sanitary sins, and curiously enough the name has been applied to a group of affections which, far from depending absolutely on cold, are frequently the direct result of living in close, overheated surroundings having a lower relative humidity than the driest desert known to man. The word "colds" means an acute infection of the lining membranes of the nose, tonsils, throat, and larger bronchial tubes. The process may be even more extensive and amount to a general infection of the entire body. All of the breathing apparatus, excepting the smaller terminal portions in the lungs, may be involved, and as a matter of fact the disease may, and often does, spread to these, thus producing pneumonia. In this connection it may be pointed out that pneumonia kills more people in the United States than any other disease excepting tuberculosis and heart disease. Many pneumonias begin as a common cold. Colds do not produce tuberculosis, yet unfortunately what is considered as a cold may be in reality the first symptoms of the white plague. In every case, however, colds are dependent on the growth and activity of living germs which are received from other persons.—Rucker, *Pub. Health Rep.*

tissue containing occasional nests of tumor cells. The peritoneal nodules were composed of dense connective tissue, with occasional minute groups of tumor cells. The amount of connective tissue in these peritoneal nodules of carcinoma was entirely out of proportion to the number of carcinoma cells present. On the other hand, the peritoneal endothelium of the sections of the wall of the small intestine adjacent to the plaques was normal and showed no connective tissue formation.

The source of the new connective tissue formed under the influence of the radium and Roentgen rays must be looked for either in the stroma of the tumor or in the round cell infiltration that closely follows the destruction of the tumor cells by the radiations. It may be stated then that while the destruction of the tumor cells is the primary phase and the formation of new sclerotic connective tissue a secondary, it is at least as important a phase in the morphologic changes which take place in malignant tumors under the influence of radium and Roentgen rays. Furthermore, the microscopic study of this case of carcinoma of the sigmoid indicates the possibility that the proliferating capacity and the consequent clinical malignancy of a tumor may be inhibited under the influence of the radiations without the presence of any apparent morphologic changes in the tumor tissue. The deeper portions of the sigmoid tumor, as well as a certain number of the peritoneal plaques, showed morphologically unchanged carcinoma cells. Nevertheless, in over six months not a single one of the minute nodules found at the operation developed into a discrete secondary tumor, and the primary sigmoid tumor did not increase in size during the time.

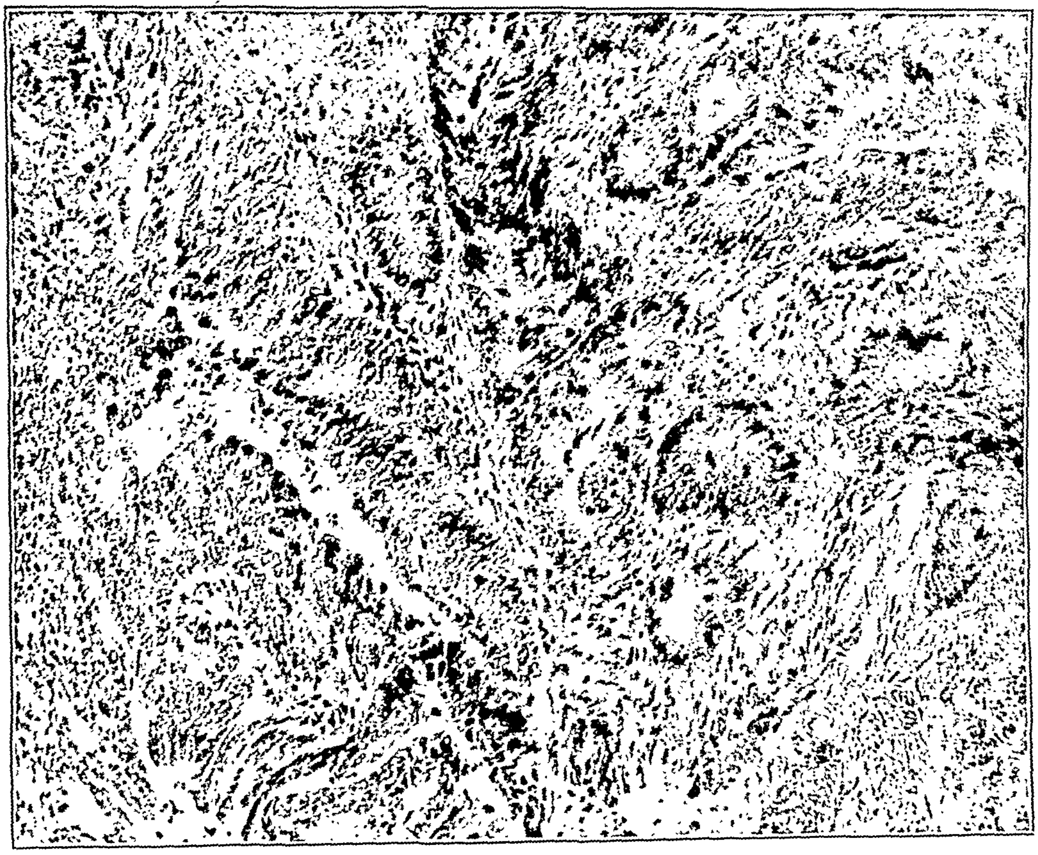

Fig. 5 (Case 3).—*Adenocarcinoma of the colon, recurrent, before treatment.*

The following series of cases, observed recently by us, present a similar condition of clinical cure without any apparent morphologic changes in the tumor tissue:

Case 1.—Mrs. W. Y., aged 40, was admitted to the Montefiore Hospital in 1906 suffering from bronchial asthma and emphysema. In August, 1915, a hard mass the size of a hen's egg was discovered in the outer margin of the right breast. The skin was adherent to the tumor, and there were enlarged glands in the right axilla. A clinical diagnosis was made of carcinoma of the breast with the involvement of the axillary glands. The general condition of the patient precluded any operative interference, and she was treated by local application of radium to the breast and axillary glands and Roentgen-rays through the chest wall. The breast tumor and the gland at first diminished somewhat in size and then remained stationary. Seventeen months later the patient died from her pulmonary condition. A complete necropsy was performed by Dr. B. S. Kline. A minute search was made for possible metastases, but none were found anywhere in the organism. The microscopic examination of the tumor of the breast showed a scirrhus carcinoma, and the lymphatic glands of the axilla were filled with solid carcinoma. Figures 1 and 2 show that morphologically both the primary tumor and the metastases in the lymph glands appeared quite malignant and did not show any changes characteristic of radiotherapy. Nevertheless, nearly a year and a half after the condition was discovered, no dissemination or distant metastases were found anywhere in the organism.

As a rule, a patient with carcinoma of the breast with the involvement of the axillary glands, if left untreated, dies in less than a year and a half from a general dissemination of the carcinoma. It is thus quite evident that in the case reported here radium and Roentgen-ray therapy inhibited the further growth and dissemination of the carcinoma tissue and transformed it, as it were, into a biologically and clinically benign type of a tumor, though it did not change its morphologic appearance.

Case 2.—Mrs. B. K., aged 40, developed a pedunculated tumor the size of a small orange on the skin of the right supraclavicular region. The tumor was removed in March, 1915, with the pedicle. There was left after the operation an ulcerated area 1 cm. in diameter that did not heal. The microscopic examination (Fig. 3) of the tumor showed it to be a melanotic cancer. The case was then referred to one of us for radium and Roentgen-ray treatment. On examination there was observed the ulceration described above and an enlarged supraclavicular lymph gland about three-fourths inch long. Under the influence of the ray therapy, the ulcer healed and the gland at first diminished somewhat in size and then remained stationary. At present, two and one-half years after the beginning of the treatment, the patient is clinically perfectly well, and no metastatic tumors have developed anywhere. Melanotic cancer is an exceedingly malignant condition, and the average life of the patient is not more than two years. Coley and Hoguet,[2] who made an exhaustive study on the subject, state that the melanotic cancer in the cervical glands is especially malignant, causing death in a short time. In October, 1916, twenty months after the beginning of the treatment, the supraclavicular gland was excised for diagnostic purposes. The microscopic examination (Fig. 4) of the gland showed a morphologic picture identical with the one found in the primary tumor before the initiation of the treatment. Nevertheless, as stated above, at present, eight months after the second operation and two years and three months after the first, the patient is perfectly well and did not develop any secondary tumors anywhere. Here again the radiotherapy inhibited the proliferating power of the cancer cells and arrested the growth of the tumor without having produced any apparent morphologic change.

---

[2] Coley, W. B., and Hoguet, J. P.: Ann. Surg., 1916, 64, 206.

Case 3.—Mr. B. G., aged 51, was operated on in December, 1915, for adenocarcinoma of the ascending colon. The tumor was radically removed and a right colostomy performed. In February, 1916, the patient was admitted to Montefiore Hospital. On admission, no recurrence of the carcinoma was found anywhere. In July, 1916, an attempt was made to close the colostomy wound by the aid of clamps, but the operation was discontinued since a recurrence was discovered at the intestinal bridge of the colostomy opening. There was felt a hard tumor mass about a cubic inch in size. The outer surface of the tumor consisted of an ulcerated area about three-fourths inch in diameter. A small piece was excised for examination, and showed microscopically an adenocarcinoma (Fig. 5). For the last ten months the patient has been undergoing Roentgen-ray treatment. He is clinically well, the tumor did not increase in size, the ulceration appears to be partly healed, and no secondary tumors or metastases developed anywhere. Recurrences in intestinal carcinoma are generally malignant, and disseminate all over the peritoneum and kill the patient very rapidly. Recently another piece was excised for examination, and the result of the microscopic study of this later specimen (Fig. 6) is very instructive. There is no direct evidence of any extensive degeneration of the cancer cells or excessive formation of new sclerotic connective tissue characteristic of radiated malignant tumors. But, unlike Cases 1 and 2, the two specimens of this case removed before and after treatment do show a certain morphologic difference. While the specimen taken before treatment shows a perfectly characteristic picture of adenocarcinoma in every field, the specimen obtained after treatment is not so characteristic, and a great many of the tubules resemble more a benign adenoma than an adenocarcinoma. These findings are somewhat difficult to explain. It is possible that the superficial, more malignant part of the tumor was destroyed under the influence of the rays. The partial healing of the ulcerated surface coincides with this assumption. The deeper portions were then inhibited by the Roentgen ray in their further malignant transformation. In any event, a clinical inhibition is quite evident in this case as well.

We have been unable to find in the literature any description of similar cases in which a clinical arrest of disease was accompanied by a complete absence of morphologic changes. Morson,[3] in his description of the various changes which occur in malignant tumors on exposure to the gamma rays of radium, states that there may take place a loss of the reproductive function of the cancer cell, but he does not illustrate this condition in any of his cases. On the other hand, there is a good deal of experimental evidence that elucidates the clinical and morphologic phenomena described in this presentation. Von Wassermann[4] reported in 1914 the results of his experiments on the action of radium on small pieces of mouse carcinoma in vitro. He has shown that the cells remain alive, but the pieces do not grow when they are subsequently inoculated in a healthy mouse. He concludes that the rays act directly on the cancer cells. However, they do not kill the cells, but impair the genuceptors or the proliferating apparatus, and as a result inhibit the formation of new cells. The actual death of the cancer cell and disappearance of the tumor is produced either through the aging of the remaining cells or through the cytolytic powers of the organism. Therefore, the rays act selectively on tissues, the cells of which are rich in genuceptors and proliferate rapidly. This hypothesis of von Wassermann fits in very well also with the frequently observed clinical fact that a malignant tumor may continue to diminish in size weeks after the ray treatment was discontinued. In a recent publication on the effects of radium on tissue growth in vitro, Prime[5] reports very similar results. He observed that radium injures the nucleus of the cells growing in animal plasma, so that it prevents further formation of mitosis. On the other hand, it does not injure the life and functions of the cell. For instance, the outwandering of the cells from the main mass of the tumor in the culture due to ameboid motion continues with the same rapidity as in the nonradiated control cultures. The beating of a piece of a heart muscle placed in the plasma culture continues for the same length of time in the radiated as in control cultures. Identical results were obtained by Halberstädter,[6] who studied the action of the radium rays on trypanosomes in vitro. The effect of the rays consisted in the inhibition of the infectivity of the parasites; that is, they lost their power to proliferate when introduced into a new host after having been radiated in vitro. On the other hand, the motility of the trypanosomes is not impaired by the action of the radium.

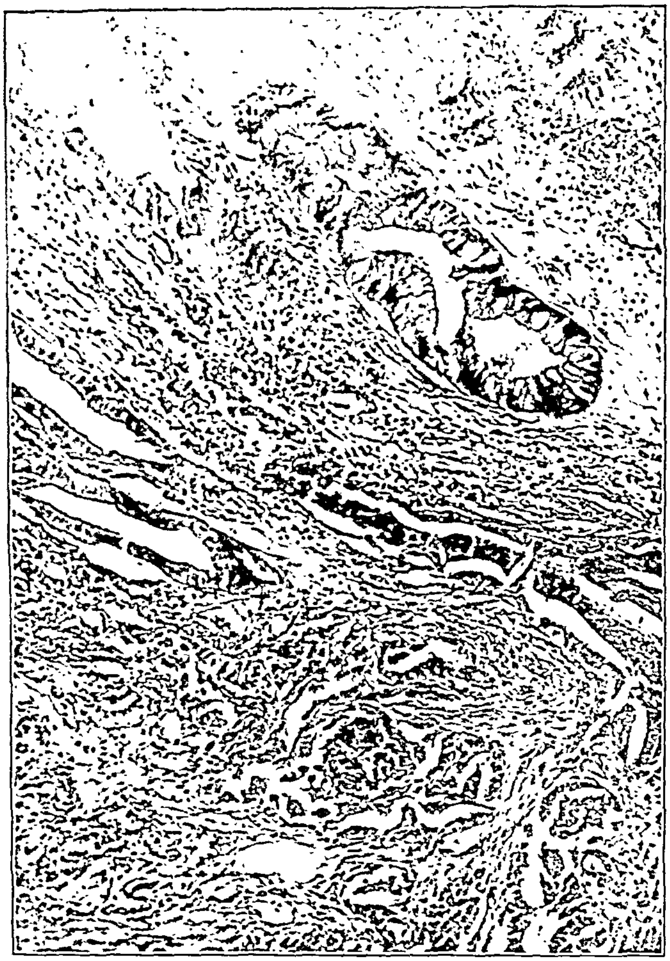

Fig. 6 (Case 3).—Adenocarcinoma of the colon after treatment.

Thus the clinical investigations reported in this presentation as well as experimental studies show that the radium and Roentgen rays may impair deeply the proliferating power and consequently the clinical malignancy of cancer cells without producing any change in the morphologic appearance of the tumor. Indeed, it is quite probable that the first effect of the rays on every malignant tumor consists in the inhibition of the proliferating power, in the *sterilization,* as it were, of the cancer cells. The degeneration and destruction of the cancer cells and the formation of the sclerotic connective tissue takes place subsequently, under the influence of the rays. Moreover, this cell degeneration and cell death may not be due directly to the action of the rays, but takes place in the natural course of the life cycle of the cancer cell. This cycle consists of youth, or period of development; maturity, or period of function; and the senility, or period of degeneration, which gradually leads to death. In parenchymatous organs, like the liver and the kidney, the first period is usually completed during embryonic life or at very early age. The second period continues through the whole life of the organism, and the third period is attained at the old age of the organism or near its death. The life of an individual cancer cell, on the other hand, is very short. It changes rapidly from an embryonic into an adult and then immediately into an aged, degenerated cell, and this process takes place continually irrespective of any extrinsic aid. But in a malignant tumor the majority of the cancer cells are quickly rejuvenated before they reach senility through the fact that each cancer cell changes into two young daughter cells. When the rays arrest this proliferation, then the cancer cells without any further outside aid mature and degenerate. It is interesting to note in this connection that the life of the epithelium of the skin or testicle is nearly as short as the one of the malignant tumors, and the rays act on these organs as specifically as they do on malignant tumors.

[6] Halberstädter, L.: Berl. klin. Wchnschr., 1914, **51**, 252.

The importance of this observation is twofold. In the first place, the morphologic appearance of radiated tumor tissue is not an absolute criterion of the therapeutic effect produced by the action of the rays on the tumor. Positive finding of the changes described above as characteristic of the action of the rays is an indication of a therapeutic result. Negative findings, on the other hand, do not preclude the possibility that the tumor was influenced by the rays. Radiated and nonradiated carcinoma tissues may have the same microscopic appearance, and still the former tissue is sterilized and may have lost to a great extent its power of proliferation and consequently its clinical malignancy. In fact, the same holds true for various malignant tumors without any relationship to radiotherapy. An epithelioma may present the same microscopic picture whether it belongs to a comparatively benign, slowly growing ulcus rodens of the face or to a highly malignant epithelioma of the lip. The second point of great practical importance to be derived from this investigation is that the radium and Roentgen rays are capable in a certain number of cases of sterilizing or inhibiting the malignancy of a tumor without destroying it. It is imperative, therefore, to subject every malignant tumor to treatment by the rays, before the performance of the radical or partial operation. The same holds true of postoperative treatment. The rays may sterilize and inhibit the proliferation of the remaining cancer cells, even if they do not destroy them outright.

ABSTRACT OF DISCUSSION

Dr. Henry Schmitz, Chicago: We must accept the dictum that the radiosensibility of cells depends on various factors. The action of radium is direct and indirect. The direct action causes degeneration of the cells whereby mitosis ceases. The indirect action is a systemic one which, as yet, we cannot explain.

Tumors arise not by the avidity of the tumor cells, but by a decrease of the avidity of the normal body cells. If the resistance of the host declines until it reaches a point where the carcinoma cells overpower the normal cells, then growth of the tumor follows. The question is whether it is not the systemic influence of the rays, that is, the indirect action, which brings about the cessation of growth of the tumors. The direct action of the rays on the carcinoma cells varies and depends on various factors—in the first place, on the specific character of the cells—the less differentiated the cell is the more radiosensitive will it be. It also depends on the age of the bearer of the cells. We know that the rays act very much more readily and intensely in the young than on adults. Cancers also are more malignant at this period. This behavior results from the fact that the cells of the young are more profusely nucleated; the blood supply is more abundant. In the aged, however, the nuclei become fewer and the blood vessels contract by a process of arteriosclerosis, as occurs during senility or decline of life. The carcinoma cannot grow as rapidly. The tumor also will react less powerfully to the rays. The radiosensitiveness of cancer also depends on the structure of the growth. A carcinoma which is very rich in connective tissue is less easily influenced by the rays than one which consists principally of cells.

The indirect or systemic action of the radium rays may result from the splitting up of the cancer cells whereby a cell protein is liberated. This in turn is followed by a leukopenia. In patients in whom we observe a favorable reaction, this negative phase is followed by a leukocytosis and lymphocytosis. Could this fact not be construed as representing an increase in the protective powers of the host and thus explain the observation of Dr. Levin that a cessation of the growth of the tumor occurred, though apparently typical carcinoma cells were found in subsequent examinations?

Dr. Alfred Woelfel, Chicago: In another section, in which a paper on the effect of radium was discussed, the statement was made that the effect on the pathogenesis depended on the malignancy being in a state of active mitosis, as I understood it; that no effect was to be expected from radium rays unless the cells were in a state of active mitosis or unless use was made of the caustic rays. Dr. Levin, however, explains the irradiation effect as consisting of an interruption of the proliferating power of the cells. I would like Dr. Levin to explain that a little more fully. I gather from his paper that he means that the action of the rays on the pathogenesis is not limited to the time in which the cells are in an actual state of mitosis.

Dr. James Ewing, New York: I have often observed the condition which Dr. Levin presented and which others also have observed. I do not think, however, that any of us have wanted to commit ourselves to the view that the physical treatment of cancer can rest with the production of this state of suspended animation in cancer tissue. In practically all Roentgen-ray and radium clinics there are patients who are doing fairly well, but who still have obvious signs of the disease and whose tissue shows that the tumor cells are still in an excellent state of nutrition, and sometimes with a mitotic process going on. The disease is still there but the patient is doing very well. Yet their condition is very unsatisfactory, both to the surgeon and to the Roentgen-ray therapeutist.

The tendency is to do something more for these people and to attempt to destroy these cells, and the result in most instances is unfortunate. I am inclined to think that in the treatment of inoperable cases of advanced carcinoma by physical agents we shall have to come to the conclusion that all that can be expected is to bring the tumor to the state of suspended activity described by Dr. Levin; and if we can add to the duration of life by 10 per cent. of the present expectation, we shall have accomplished a great deal. It may be that physical therapy will have to leave to other methods the final solution of this problem.

As for the direct and indirect effects of physical agents, that is a matter in which there is a difference of opinion. Until we know a good deal more about the indirect effect of the rays, we had better trust to the direct effects.

Dr. Isaac Levin, New York: I need not reply to Dr. Schmitz's question, since Dr. Ewing has answered it. There is no direct proof of the existence of a secondary immunizing effect of the rays on the organism, and for the present we must accept only the direct action of the rays on the malignant tumor. The pathologic and clinical evidences of malignancy do not always coincide. A pathologist cannot decide from the microscopic appearance whether the specimen is derived from an ulcus rodens or an epithelioma of the lip. Clinically, on the other hand, the former is a comparatively benign condition, while epithelioma of the lip belongs to the most malignant types of cancer. The same is true of the case of melanotic cancer described in the paper; the condition surely lost its clinical malignancy since the treatment was initiated. Still the two specimens taken before and after treatment show an identical microscopic picture.

The comparative number of mitotic figures found in a microscopic specimen is also no direct indication of clinical malignancy. There are round cell sarcomas which show under the microscope a great many mitotic figures but which are clinically comparatively benign.

The first action of the rays on the cancer cells consists most probably in the inhibition of their proliferating power without any degeneration and actual destruction of the cell. The latter follows subsequently. It is true at the same time that when this stunning, as it were, of the cancer cell is not followed by its destruction, then it may ultimately recover, and a recurrence of the tumor will take place. The same process probably takes place when the tumor recurs twenty years after a radical operation.

OILED GAUZE AND THE ABSORBING POWER OF COTTON SPONGES*

TORALD SOLLMANN, M.D.
CLEVELAND

"Nonadhering surgical gauze" was introduced by H. E. Fisher.[1] It was prepared by saturating the gauze with a soft paraffin mixture made by the addition of petrolatum, lanolin or stearic acid to paraffin. Fisher asserts especially that the blocking of the fibers prevents matting with secretions and débris; that it prevents adherence of the gauze, and that the granulations of tissue repair are not injured when the dressing is removed.

While working on paraffin bandages, I became interested in the permeability of such bandages as influenced by various waxes and oily preparations. A series of gauzes of loose and close mesh were prepared by impregnating them with paraffins of different hardness, ranging from hard paraffin to liquid petrolatum.

As the result of experiments I find that "oiled gauze," that is, gauze that is impregnated with liquid petrolatum, holds out considerable promise of usefulness. Cotton sponges wrapped in this oiled gauze absorb viscid fluids very much better than when wrapped in plain gauze; the gauze is soft and pliable; it is easily prepared, and it can be sterilized by heat after impregnation.

In the course of the investigation a loose mesh cheesecloth and a close mesh muslin were compared; it was found that the former permits much better absorption. I also used a series of mixtures of paraffins[2] for impregnating the gauzes, but found that liquid petrolatum alone is superior. This oiled gauze is prepared by dipping the cloth into the liquid petrolatum and expressing out the excess.

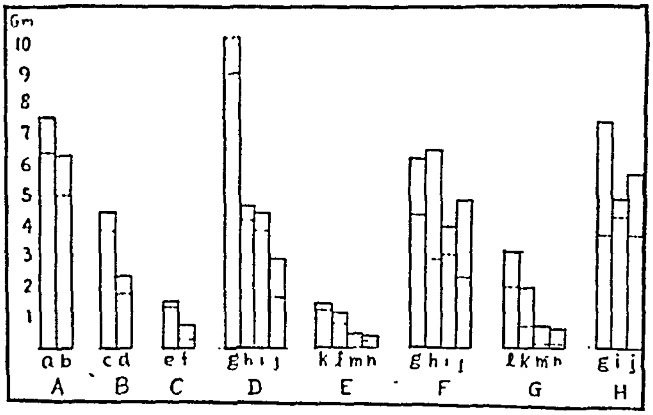
The technic of making the absorption tests was as follows:

Sponges were prepared by wrapping 1 gm. of absorbent cotton in a piece of the gauze, 12 cm. square. Egg white and egg yolk were used to simulate wound discharges. The egg white or egg yolk was placed in a flat bottom pan, in a layer perhaps 2 to 3 mm. thick; and in this were placed the sponges, which had previously been weighed. The sponges were reweighed at intervals. The results are shown in detail in the chart.

The results of the experiments may be thus summarized:

1. Sponges made of compressed cotton[3] absorb better than those made of loose cotton.

2. Sponges made with the cotton layers parallel to the surface absorb much better than those made with the layers vertical to the surface.



Absorption of fluid by sponges: The dotted line shows the grams of fluid absorbed in one hour, and the solid line that absorbed in twenty-four hours. *A* to *E* represent the absorption of undiluted egg white; *F* and *G* that of undiluted egg yolk, and *H* that of beaten egg. *A*, comparison of (*a*) compressed and (*c*) plain cotton, wrapped in cheesecloth; *B*, comparison of cotton applied (*c*) horizontally and (*d*) vertically; *C*, comparison of (*e*) cotton in muslin and (*f*) charcoal in muslin; the cotton, as in all these experiments, weighed 1 gm.; the charcoal pad contained 4 gm. of granular charcoal; *D* to *H*, comparison of treated and untreated gauze; (*g*) Stanolind cheesecloth; (*h*) 50 per cent. Stanolind cheesecloth; (*i*) plain cheesecloth; (*j*) Fisher cheesecloth; (*k*) plain muslin; (*l*) Stanolind muslin; (*m*) 50 per cent. Stanolind muslin; (*n*) Fisher muslin.

3. The sponges wrapped in loose mesh fabric absorb somewhat better than those wrapped in close mesh fabric.

4. Sponges filled with cotton absorb much better than those filled with powdered charcoal.

5. Sponges covered with gauze impregnated with liquid petrolatum absorb very much better than sponges covered with plain gauze.

6. Sponges covered with gauze impregnated with 50 per cent. liquid petrolatum are intermediate.

7. Sponges covered with gauze impregnated with Fisher's mixture do not absorb as well even as those covered with plain gauze.

8. The influence of oils, etc., on absorption is practically the same for loose mesh as close mesh gauze; and for egg albumin and egg yolk.

---

[1] Fisher, H. E.: Nonadhering Surgical Gauze, The Journal A. M. A., March 25, 1916, p. 939.

[2] The following paraffins and oils were employed: hard paraffin (Parowax brand); 20 per cent. white petrolatum: paraffin (Parowax), 80 parts, white petrolatum, 20 parts (Fisher's formula); 1 per cent. naval pitch: preceding mixture with 1 per cent. naval pitch added; 50 per cent. liquid petrolatum: equal parts of paraffin (Parowax) and liquid petrolatum; liquid petrolatum (Stanolind liquid paraffin).

[3] The finished sponge was compressed in an old style letter press.

The favorable influence of the oiled gauze is explained by the protection that the oil furnishes against swelling of the thread and obstruction of the mesh.

I have not yet had the opportunity of investigating whether it is as little adhesive as the Fisher preparations; but it is certainly more favorable to absorption, and I would therefore suggest its use for dressing moist wounds.

ECLAMPSIA AND LUMBAR PUNCTURE

J. W. SNYDER, M.D.
MICHIGAN CITY, IND.

At 1 a. m., April 23, 1917, I was called seven miles from town to see Mrs. W., aged 25, with her first child. Pains had begun at 4 p. m. the preceding afternoon, and at 11:30 she had a convulsion. By the time I reached her she had had four convulsions, and a fifth quickly followed. In the intervals she was delirious, tossing about the bed. Restraint was necessary to keep her on the bed at all. On hasty examination I found the cervix dilated and the head in left occipito-anterior presentation on the perineum; but the patient seemed to be unable to deliver the child, mainly because she made no intelligent effort to aid the labor pains. Being alone, except for the assistance of an excited husband and a grandmother who could not speak English, I gave the patient ether and made a forceps delivery. When the patient recovered I gave her ½ grain of morphin, and as the convulsions were returning I ordered her removal to the city hospital, to which she was admitted at 4:30 a. m. On catheterization, 4 ounces of urine were obtained which tested over one-half albumin by volume, and also gave a decided reaction for diacetic acid. One thousand c.c. of physiologic odium chlorid solution were given under the breast, followed two hours by 1,000 c.c. of sterile water. Sodium bicarbo-e and glucose solution were given by bowel. One-fourth ain of morphin and 1/200 grain of scopolamin were administered by hypodermic injection and repeated in two hours. Two minims of croton oil were given on the tongue.

Four hours after admission, the temperature was 102, the pulse 108 and the respirations 34. Six convulsions had occurred in the four hours' time. In the next two hours there were four convulsions more severe than those that had occurred before. The temperature went up to 105.2 by axilla, the pulse was 130, and the respirations were 36. One three-hundredth grain of scopolamin and 1/6 grain of morphin were given, and in the next hour three more convulsions occurred. At 11 o'clock the temperature was 106 by axilla, the respirations 34 and the pulse 140, very weak and irregular. The breathing was shallow and irregular, with considerable edema at the base of the lungs. The face was congested and cyanotic. As a last resort I did a spinal tap, not expecting any good, as I thought the patient would be dead inside of an hour. The spinal fluid did not seem to be under much increase of pressure, flowing slowly in drops and being perfectly clear. About 2 drams were removed and no more because I could see no reason to expect benefit from it. Before I left the room the appearance of the patient had changed. The face began to lose much of the congested appearance, and the respirations became more regular and deeper. Within one hour the temperature had fallen to 105, the respirations were 34, and the pulse was 112. No more convulsions occurred. At 2 p. m. the temperature was 103, the pulse 108, and the respirations 30, and 26 ounces of urine were removed by catheter.

From that time on the patient made a steady recovery. The temperature reached normal on the third day, and the patient recovered consciousness on the evening of that day. She had no recollection of labor or anything following. Sodium bicarbonate and glucose solution was continued by bowel for several days, and the bowels were thoroughly evacuated. The patient left the hospital, May 5, in good condition except for some necrosis at the point of giving hypodermoclysis.

This case may be only an accident, but I believe that in similar cases the procedure merits repetition. It is, of course, not a measure to remedy the toxemia, but only a means to control the convulsions. I have found a report by W. T. Wilson[1] regarding this procedure in two cases of eclampsia with beneficial results. Recently Musser and Hufford[2] reported a series in which lumbar puncture controlled the delirium of pneumonia. I believe the procedure is used also with advantage in the delirium of alcoholism and to control convulsions in meningitis.

THE TREATMENT OF EPIDEMIC POLIOMYELITIS WITH IMMUNE HORSE SERUM*

PRELIMINARY REPORT

E. C. ROSENOW, M.D.
ROCHESTER, MINN.

In a previous report,[1] it has been shown that the serum of a horse, which had been immunized with streptococci isolated from the central nervous system of monkeys paralyzed with virus, had the power to neutralize virus in vitro, and to prevent poliomyelitis in monkeys following intracerebral inoculation of active virus. Moreover, this serum appeared to have a curative effect in the experimental disease in monkeys after the symptoms had begun.

Opportunity to test the effect of this serum in patients presented itself during the present epidemic of anterior poliomyelitis at Davenport, Iowa, and surrounding community. The routine procedure consists of making a spinal puncture for diagnostic tests and for relief of abnormal intraspinal pressure, and of injecting the serum. From 5 to 30 c.c. of spinal fluid are allowed to escape, depending on the age of the patient and the amount of pressure. The fluid is made to flow slowly because it is believed that rapid withdrawal might be harmful. The cell count and Noguchi's globulin test are made at the bedside, and if positive, the injection of serum is given at once. The serum is activated with complement by adding one part of fresh guinea-pig serum to nine parts of the immune serum and incubating at 37 degrees for one hour. It is then diluted with equal parts of 0.85 per cent. salt solution. The diluted serum is injected slowly into a suitable superficial vein not later than thirty-six hours after activation. Approximately 2 c.c. of the mixture are injected per minute of time. The dose is varied according to the age of the patient and severity of the symptoms. Babies from about 1 to 2 years of age are given from 3 to 7 c.c. of serum at each injection, that is, 6 to 14 c.c. of the mixture; children from 2 to 5 years of age from 7 to 10 c.c., and older individuals from 10 to 20 c.c. The injections are repeated in from eight to twenty-four hours if necessary.

Every patient in whom the diagnosis is definite, and the disease still active, is given injections of serum irrespective of the severity of symptoms. Altogether forty-four patients have been treated. Of these nine died, a mortality of 20 per cent. Of the nine fatal cases, six were moribund, or in a dying condition from respiratory failure at the time the serum was given, and hence should not be included as treated cases. Of the thirty-eight patients in whom there was sufficient time for the serum to act, three died, a mortality of 8 per cent. One of these was a baby 11 months old, semicomatose with spasms eight days after onset of the illness when the serum was first given. One, a boy 2 years old with cyanosis, marked tremors, high fever, severe gastro-enteritis and beginning respiratory paralysis on the second day at the time of the first injection; and one, a girl 11 years old, with high fever and paralysis of the face on the third day when the first dose of serum was given. Of these thirty-eight treated cases, twenty-two showed definite paralysis when the treatment was begun, and sixteen were in the preparalytic stage. Excepting the three fatal cases in the former group, paralysis appeared to be arrested in all but one, a boy 5 years of age, in whom a moderate paralysis developed in the left leg, the first injection of serum being given on the second day of the disease. All of the sixteen cases treated before paralysis had begun recovered without paralysis.

* From the Mayo Foundation.

[1] Rosenow, E. C.: The Production of an Antipoliomyelitis Serum in Horses, The Journal A. M. A., July 28, 1917, p. 261.

These results are in sharp contrast to the twenty-three untreated cases which occurred during this epidemic of which nine patients died, a mortality of 35 per cent.

The apparent good effects from the injection of serum are often striking. The headache, nervousness, restlessness and tremor often disappear promptly. The temperature and pulse rate are lowered. A beginning paralysis often disappears in an astonishingly short time. A rapidly progressing paralysis is often arrested and improvement is unusually rapid. The postparalytic pains do not appear or are comparatively mild. It is believed that the unactivated serum would do good, and that intraspinal injections might be given with benefit, but since the activated serum and intravenous injections have given the best results in monkeys, and are yielding such splendid results in patients, I have not felt justified in changing the method. Intravenous injections in this epidemic appear especially desirable because the gastro-intestinal symptoms are so pronounced.

It is, of course, realized that many more patients must be treated before conclusions can be drawn as to the exact value of this treatment. Of its harmlessness and apparent good effects, there can scarcely be any question. There is on hand enough serum to treat approximately 800 patients. Suitable quantities will be sent gratis on request to physicians or laboratories for reports of cases in localities where poliomyelitis now exists in epidemic form.

I wish here to express my very great appreciation for the courtesies extended me in the use of the Pathological Laboratory at Mercy Hospital, and of the splendid cooperation of the physicians making it possible to treat the disease in the early stages.

The Panama Canal in Switzerland.—At the meeting of the Zurich Medical Society, March 10, a lantern slide lecture on the Panama Canal was delivered by Lieutenant Lutz, who described the conquest of yellow fever and malaria, and the practical results at Panama. It is mentioned merely as an example of the internationalism of science, enthusiastic credit being paid to the Americans and to Finlay of Cuba, with comment on the inevitable failure of the French, at that stage of science, the Swiss audience, and the speaker an interned German officer.

SIMPLIFIED METHOD FOR THE PREPARATION OF CARREL-DAKIN SOLUTION

FREDERIC ROSENGARTEN
PHILADELPHIA

The preparation of neutral solution of chlorinated soda by the process described by Carrel and Dakin requires more or less chemical skill and equipment. With the proposed process nearly any one can prepare the solution without the use of chemical apparatus and within ten or fifteen minutes.

The materials and process for preparing the solution are:

1. Chlorinated soda solution, which should contain from 2.8 to 2.9 per cent. of available chlorin.
2. An approximately 5 per cent. aqueous solution of sodium bicarbonate.
3. Phenolphthalein powder.

Dilute 1 volume of the chlorinated soda solution with 5 volumes of water, add 25 c.c. of the sodium bicarbonate solution for every liter of chlorinated soda, and mix well. Now remove about 20 c.c. of the solution, add to it a small pinch of phenolphthalein, and shake gently for two minutes. If no red color appears, the solution is ready for use. Should a red color develop, add from 10 to 20 c.c. more of sodium bicarbonate to the solution, mix well, and test for free alkali with phenolphthalein as described above. Repeat the addition of sodium bicarbonate if necessary, until 20 c.c. of the solution show no red color when tested with phenolphthalein in the manner described above. A slight excess of sodium bicarbonate will probably not affect the quality of the solution.

The objection to the use of ordinary chlorinated soda solution for the treatment of wounds is that the solution almost invariably contains caustic alkali, which causes an irritation of the tissues. To overcome this, Carrel and Dakin use also sodium bicarbonate in the preparation of their solution, the sodium bicarbonate serving to neutralize any hydroxid present in the chlorinated lime. The same principle is applied in the proposed process, the only difference being that the sodium bicarbonate is added to the already prepared chlorinated soda solution. It is, however, this very difference that makes the preparation of the solution very easy because chlorinated soda solution of from 2.8 to 2.9 per cent. available chlorin is readily obtainable and keeps well when properly preserved; all that is necessary is to dilute the solution and neutralize it with sodium bicarbonate.

Since the solution prepared by the proposed process is *free of caustic alkali* and contains the same amount of available chlorin as that prepared by the Carrel-Dakin process, it is reasonable to expect that it will have the same therapeutic value.

Neither of the solutions will keep for a long time, but if we can judge from one comparative experiment carried out with each solution, the one prepared by the proposed process retains its value for a longer time than the solution prepared by the Dakin process. Thus while the latter solution containing, when prepared, 0.47 per cent. of available chlorin, showed only 0.41 per cent. at the expiration of two weeks, a solution prepared by the proposed process and also originally containing 0.47 per cent. of available chlorin still tested 0.44 per cent. after three weeks.

Military Medicine and Surgery

DICHLORAMIN-T IN THE TREATMENT OF THE WOUNDS OF WAR

JOSHUA E. SWEET, A.M., M.D.
Captain, Medical Reserve Corps, United States Army;
Surgeon, Base Hospital No. 10
FRANCE

It seems to be agreed that the chlorin compounds which have been derived from the old Labarraque's solution have given, in general, the best results in the treatment of the wounds of the present war.[1] I do not mean that equally good results have not been obtained by certain workers with hypertonic salt solution, or that equally good results have not been obtained by the proper utilization of the fundamental surgical principle of drainage, without the use of any antiseptic or lymphagogue whatever.

These chlorin-containing solutions, variously known as eusol,[2] Dakin's solution and Daufresne's solution, have suffered from two serious faults. They are not particularly stable, and must be prepared with care. Further, these solutions contain so little antiseptic value that they must be frequently renewed in the wound.

The latter fault has been overcome by the methods which have been devised for frequent renewal of the antiseptic solution, as often as may be necessary, without disturbing the entire wound dressing. The best known of these methods is the Carrel tube. It should be emphasized that the Carrel tube is not a surgical method in itself; it is not the essence of wound treatment; a few Carrel tubes placed in a wound will not heal the wound; the tubes must be used to convey the antiseptic frequently to the recesses of the wound. I mention this because it has seemed as though some surgeon had not quite grasped the point.

It is further quite certain that the use of the Carrel tube has led many surgeons far away from the surgical principle of free, dependent drainage, a principle established by centuries of surgical experience. Therefore we constantly find wounds constructed by the surgeon in direct opposition to the laws of gravity and surgery, wounds which do not heal kindly even when "puddled," but which would have healed of themselves if they had been given wide dependent drainage.

These facts were perfectly clear to Dakin's mind and led him to seek for a more effective chlorin compound, a compound which should contain enough available chlorin to suffice for a period of at least twenty-four hours, and which should be nontoxic and nonirritating. The first result of this study was chlormin-T (toluene-para-sulphon-sodium-chloramin) and later dichloramin-T (toluene-para-sulphon-dichloramin).[3]

Dr. Dakin asked Dr. Walter E. Lee, of the Pennsylvania Hospital of Philadelphia, and me to test the surgical value of the new preparation. Our solutions were first prepared by Dr. Byron M. Hendrix of the Department of Physiological Chemistry of the University of Pennsylvania, following Dr. Dakin's instructions, and later, by the Henry Phipps Institute of Philadelphia, through the courtesy of Dr. Paul A. Lewis of the institute. Our preliminary results have been reported,[4] but it has been my good fortune, with the United States Army Base Hospital No. 10, to test the effect of the new preparation on war wounds in a British general hospital in France. Our results with these wounds bear out our first report in every particular and further emphasize certain features of the method.

There are more things to be considered in the treatment of war wounds than the direct effect of the treatment on the wounds themselves, that is, if two methods give equally good results in wound healing, but the one methods is less painful, and effects a marked saving of time, labor and material, then the second method far surpasses the first.

It seems almost useless to me to discuss at any great length the results in regard to the wounds themselves, because probably equally good results can be obtained by the proper use of any method, so far as final wound healing is concerned; and further, surgeons are so constituted that they do not believe any other surgeon's results, anyway, until they have tested his methods for themselves — doubtless a most praiseworthy attitude of mind in a profession in which new suggestions for old and tried methods are rather numerous.

We have treated some eighty patients with Dakin's dichloramin-T; some have been old cases with foreign bodies lying in the bone, and suppuration did not stop until the foreign body was removed. Fresh cases in which the casualty clearing station has left us enough integument to permit it have been treated with dichloramin once and immediately closed and have healed by secondary intention. Sixteen cases, old and fresh, were cultured after treatment with dichloramin-T for varying periods, of which eleven gave no growth whatever; of the five in which a growth appeared, four were old cases of deep bone involvement; the only growth was the *Staphylococcus aureus* in four cases and in one case the pyocyaneus.

The wounds fill rapidly with granulation tissue of healthy color which exhibits no tendency to exuberant growth and no tendency to become water soaked and indolent; the skin edges grow in very rapidly.

These results are no different from those which can be obtained by other methods, and no one would believe them if they were any better. Let me say, therefore, that the surgeons of the unit are agreed that the wounds treated by dichloramin-T are in every way as satisfactory as they have ever seen under any method; and two of our surgeons have had previous experience in France, while all are surgeons of long experience in civil practice.

---

[2] "Eusol" is a contraction of "Edinburgh University Solution." This is the acid hypochlorite solution advocated by Lorrain Smith. Quoting Useful Drugs, Edition 2, page 44: "The acid solution (Lorrain Smith's) may be prepared by shaking 12.5 gm. of chlorinated lime and 12.5 gm. powdered boric acid with 1 liter of water, allowing the mixture to stand for some hours, and filtering. The neutral solution (Carrel-Dakin's) is made by dissolving 14 gm. of anhydrous sodium carbonate in 1 liter of water, adding 20 gm. of chlorinated lime, shaking the mixture, after half an hour siphoning off the supernatant fluid from the precipitated calcium carbonate, filtering and neutralizing by adding boric acid (usually 2.5 to 4 gm.) until a drop of the solution does not redden a few drops of phenolphthalein solution. The alkaline preparation of *hypochlorites* is represented by the solution of chlorinated soda U. S. P. described below. Unless strongly alkaline, solutions of hypochlorites decompose rapidly."

[3] For a description of the method of preparation of the dichloramin-T and the chlorinated oils, see Dunham, E. K., and Dakin, H. D.: Brit. Med. Jour., 1917, **1**, 865. Dakin, H. D.; Lee, W. E.; Sweet, J. E.; Hendrix, B. M., and Le Conte, R. G.: A Report of the Use of Dichloramin-T (Toluene-Parasulphondichloramin) in the Treatment of Infected Wounds, The Journal A. M. A., July 7, 1917, p. 27.

[4] Dakin et al., *Footnote 3.*

The results along other lines are capable of more definite demonstration, and it is on these that I would lay the most emphasis.

This new dichloramin solution is made by dissolving the crystals of dichloramin-T in chlorinated eucalyptol and then diluting this solution by the addition of chlorinated paraffin oil. It is best applied by an oil spray, an ordinary hard rubber or all glass atomizer being the most practical method. Metal atomizers are not suitable, since the metal is attacked by the chlorin.

This oily solution presents the first great advantage — the dressings do not stick to the wound, and the entire act of dressing is relatively painless.

The gauze does not have to be separated from the granulations by soaking with some liquid or other. It is therefore not even necessary in the average wound to place a waterproof protective covering over the bed linen while dressing, and the necessity of moving the part or the patient is obviated. The old dressing is simply lifted off, and the wound sprayed; the force of the spray will dislodge sloughs, and the wound is covered with a fresh dressing.

It is perfectly evident that a very important saving of time results from this simplicity of dressing. One surgeon has repeatedly dressed thirty wounds in ninety minutes, an average of three minutes to each dressing. These figures and the figures to be given later refer to the acute wards, in which the patients are all bed patients.

The solution contains enough available antiseptic so that one dressing every twenty-four hours is ample for large, deep wounds, and one dressing every forty-eight or seventy-two hours is enough for the simple or more superficial wounds. Since the solution contains so much available chlorin and does not have to be renewed every few hours, the use of the Carrel tube is entirely done away with. The oily solution of dichloramin-T creeps into all the wound crevices and corners, and it can be readily introduced into sinuses by means of a cotton swab dipped into the solution.

TABLE 1.—COMPARATIVE USE OF MATERIAL, JULY 5, 1917

Wards	Gauze, 6-yd. Rolls	Cotton, 1-yd. Rolls	Treatment	No. of Patients
1	12	2.5	Eusol	23
2	10	4	Eusol	22
3	3.5	2.5	Dichloramin-T	23
4	6	2.5	Eusol	25

The amount of this new solution needed for wound dressing should be emphasized. At first thought it would seem that a solution containing oil of eucalyptus and liquid petrolatum would be far too expensive for general use in comparison with eusol. Forty-two wounds were dressed by one surgeon with 35 c.c.; another surgeon dressed 154 wounds with 115 c.c. These figures apply to the acute wards, and include many compound fractures and extensive buttock and thigh wounds. The fact that so little fluid has to be used and that therefore only the wound discharge has to be cared for results in a tremendous saving of gauze and cotton. In Table 1 are given the results of a comparison of the amounts of gauze and cotton used during different periods in the four acute surgical wards of the hospital. Each ward is in charge of surgeons of equal skill and all trained in the same hospital; the nurses are also all graduates of the same hospital training school; in other words, the comparison is not between workers trained in different schools of surgical technic.

Table 2 gives the amount of gauze and cotton used in seven days in three of the acute surgical wards. Ward 2 changed during this period from the use of eusol to the use of dichloramin-T; the figures from this ward are therefore not available. The number of patients was the same in the three wards and the proportion of relatively slight and extensive wounds in each ward was the same.

This saving of material is of importance in several ways. It effects not only a saving of labor from the cotton field to the hospital, a saving of transport, but also an important saving in the hospital itself; the time taken by the nurses in the preparation and sterilization of material can be utilized for the care of the patients, and to this can be added the saving in time, labor and material by doing away entirely with the need for the Carrel tubes.

TABLE 2.—COMPARATIVE USE OF MATERIALS, JULY 4, TO JULY 10, 1917, INCLUSIVE

Ward	Gauze, 6-yd. Rolls	Cotton, 1-yd. Rolls	Treatment
1	72	38.5	Eusol
3	33	7	Dichloramin-T
4	45	18	Eusol

The need for so little solution in wound dressing and the fact that the dressing need be sufficient only to care for the wound discharge means that the bed linen is not wet, with a consequent saving in the moving of the wounded and an increase in their comfort and well being.

The dichloramin-T solution, like all the other chlorin compounds, is a very active lymphagogue in fresh wounds, and the amount of wound excretion may be considerable. The lymphagogic effect may be directly watched in suitable wounds. As granulation tissue develops, the lymph discharge greatly decreases until the wound becomes comparatively dry. The dichloramin-T also possesses to a marked degree the characteristic power of the chlorin solutions in aiding the digestion and removal of necrotic, sloughing tissues. The new solution seems more effective in cleaning up sloughing tissue than the older chlorin compounds. While the majority of our cases come from the casualty clearing station in excellent, clean condition, a sufficient number have reached us with necrotic tissue in the wound amply to satisfy us of the rapidity with which the dead tissue is freed under the dichloramin-T. The tendency to secondary hemorrhage is certainly not increased. We have had but one secondary hemorrhage in the series, which includes a number of deep buttock wounds, and cases of exposed great arteries of the arm and leg.

The solution is not irritating to the skin or mucous membrane, except possibly in the rare individual who possesses an idiosyncrasy to the eucalyptus oil. Such individuals have been reported in dermatologic literature. Among the patients treated here we have encountered only one dermatitis; but since the dermatitis did not develop until after two weeks' use of the solution and was accompanied by high temperature, it is not clear whether it should be ascribed to the oil or to the well known action of wound excretion.

The constituents of the solution are stable, although the final combination is not indefinitely stable, nor can it be exposed to strong light. It is easily prepared from the constituents. The dichloramin-T which I have was put up in packages of 10 gm. each; the content of one package is dissolved in 75 c.c. of chlorinated eucalyptol and diluted with equal parts of chlorinated paraffin oil as needed, making, therefore, approximately a 6.5 per cent. solution of dichloramin-T.

The first application of the solution to a fresh wound produces a smarting or burning sensation, which passes away in a very few minutes; in some individuals this seems quite severe, but I have yet to see the patient who does not prefer this slight smarting to the real pain of removing a wet dressing which has dried around the edge of the wound. After the second or third application the smarting sensation on applying the solution seems to have disappeared.

Since the time to treat an infection is before the infection starts, it is hoped that the dichloramin-T solution can be given an early trial at the field ambulance and casualty clearing stations.

CONCLUSIONS

Dakin's dichloramin-T in solution in eucalyptol and paraffin oil is therefore of great advantage in wound treatment, even if the final results in wound healing were no better, because:

1. It saves the pain of wound dressing.
2. It effects an appreciable saving of dressing material.
3. The amount of solution is of small bulk.
4. The number of wounds which a surgeon can ss in a given time is far greater than by any other thod.
5. The elimination of the Carrel tube simplifies the dressing and the problem of transportation of the wounded.
6. The elimination of the Carrel tube saves the time taken by the nurse for the periodic flushing.

EQUILIBRIUM TESTS FOR AVIATION RECRUITS

CHARLES P. SMALL, M.D.

CHICAGO

Because of the unusual conditions confronted by the aviator, the physical examination of candidates for this branch of the government service is more rigid than for any other branch. Among the most important tests are those for determining the sense of equilibrium. The Bárány rotating chair, or the Jones modification of the chair is used (Fig. 1).

THE BÁRÁNY CHAIR

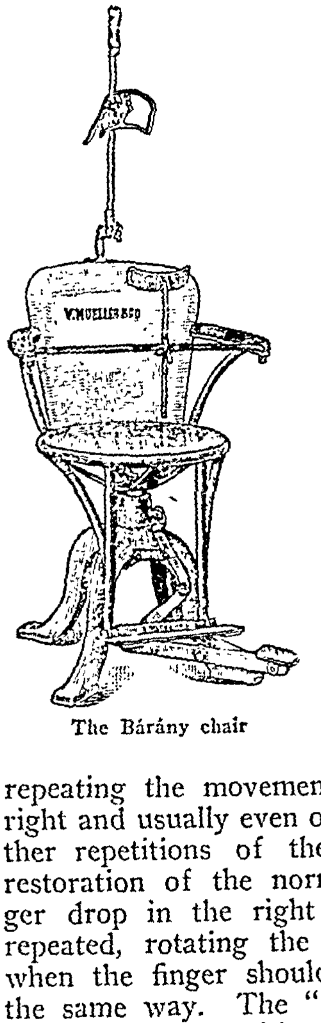
The essential factors in the construction of the chair are a foot-rest to allow the person examined to be revolved freely with his feet resting on the foot-rest, a few inches above the floor; a head-rest to hold the head firmly at the desired angle; a stop catch by which the examiner by pressing with his foot can instantly bring the rotating chair to a stop; and a long arm extending upward behind the chair at a slight angle, by means of which the examiner is able to rotate the chair easily. Before making the tests it is well to have the applicant's ears examined to see that there is no impacted wax in the external auditory canals, also to ascertain the condition of the eustachian tubes, that is, whether or not they are patulous. Applicants are advised to eat a very light luncheon before having this examination, as nausea and vomiting occasionally follow the test.

METHOD OF EXAMINATION

The examiner is provided with a stop-watch. The applicant sits with eyes closed and his feet on the foot-rest; his head is against the head-rest tilted at an angle of about 30 degrees. The chair is rotated ten complete revolutions toward the right in exactly 20 seconds. The chair is then brought to a sudden stop and the applicant is told to open his eyes and look straight in front of him at some distant object. If his horizontal canals are functioning normally, there will be a lateral nystagmus, to the left, continuing for about 25 seconds, although a variation of 10 seconds below or beyond this time is allowable. The process is then repeated, turning the chair this time to the left, which will produce a nystagmus to the right.

THE POINTING TEST

The "pointing test" is next made, as follows: The examiner stands directly in front of the chair, and the applicant sitting erect with his eyes blindfolded is told to extend his right arm directly in front of him and with his forefinger touching the finger of the examiner held at that point. The applicant is now told to raise his arm above his head and quickly bring it down again to exactly the same spot, that is, to touch the examiner's finger when he brings his arm down. He is then made to do the same thing with his left arm.



The Bárány chair

The applicant now assumes an easy position with his arms resting on the arms of the chair; the chair is rotated rapidly to the right, ten times in 10 seconds. The instant the chair is brought to a stop, the examiner again holds his finger in contact with the applicant's right forefinger directly in front of him, and the applicant is again told to raise his arm and quickly bring it down to touch the examiner's finger. In the normal condition the applicant will not touch the finger, but will "past point" several inches to the right of it. On repeating the movement he will again point to the right and usually even on the third attempt. Any further repetitions of the movement should show a restoration of the normal equilibrium, and the finger drop in the right direction. The test is then repeated, rotating the chair this time to the left, when the finger should "past point" to the left in the same way. The "falling test" is now made, to ascertain the condition of the vertical canals. The applicant bends his body forward at an angle of 90 degrees, his eyes still blindfolded, and his head resting on his fists held on his knees. The chair is rotated rapidly toward the right, ten times in 10 seconds. The instant it is brought to a stop the applicant is told to sit straight up. If normal he will fall toward the right side. Assuming the same bent position again, he is rotated toward the left in the same way, and on attempting to sit up straight, he will fall to the left side. The rotation method is now used exclusively in examining the sense of equilibrium, having superceded the caloric method as being more rapid, easier in application and more exact in determining the integrity of the entire vestibular function.

25 East Washington Street.

PROMPT REMOVAL OF FOREIGN BODIES IN GUNSHOT WOUNDS

ARGUMENTS IN FAVOR

KELLOGG SPEED, M.D.
Major, Medical Reserve Corps, United States Army
FRANCE

Coming back into the field of military surgery after an absence of several months, during which interval the lessons of experience have matured, I feel compelled to make an academic statement concerning early removal of foreign bodies in many gunshot wounds. In the service of the British expeditionary forces during 1916 I had the opportunity of caring for thousands of wounded men. This year, returning to the same field in the service of our own United States, and having earned the right, in part, to make general observations, the advantage of early foreign body removal strikes me most forcibly.

With the advancement of the stress of war, the increase of its countless thousands of wounded men and the refinement of efficiency and cruelty of gunfire, the services rendered by the medical corps have progressed favorably. By that I mean not so much the efficiency of individual medical officers, nor the far-seeing arrangements of general officers governing corps movements, as I do the application of simpler methods, the multiplication of excellently equipped casualty clearing stations near the line and the more active immediate treatment by qualified surgeons.

In the first eighteen months of the war, although stupendous efforts at organization of the various medical corps were put forth, and although the results were correspondingly satisfactory, the general outcome fell short of the idealism of surgical work. It was of necessity so. Medical men had to become accustomed to the work in hand, weigh it in the light of their previous experience, and observe results after many methods and months of waiting. That period passed with a lower mortality and a happier general result than any other great war has shown. New infections were encountered and studied, and their untoward results checked. Tetanus was quite firmly controlled in spite of its all-pervading possibilities in trench war.

If methods have improved, if such dreaded infections as gas gangrene are known, if tetanus can be controlled, may we not look to even better results by considering the larger problems of the medical service? Laying aside sanitation, sick men and medical disease, and dealing with wounded men and their recovery, what have we to consider? First, there is the method of gathering up the wounded, and their transportation to comfort and medical aid; secondly, the nearness of high surgical aid and its character, and lastly, the transportation to bases and home lands of the seriously wounded, and return to the firing line as soon as possible of the largest percentage of men for continued service.

When one comes to observe the expanded system of care, comfort and transportation of the wounded from the battlefield, one cannot fail to feel a deep and respectful admiration for its thoroughness. At present it is about the last word on the subject. The expansion of close lying casualty clearing stations, both in number and in capacity, with the personnel better qualified to perform rapid, clean, conservative war surgery, leads me to the points I wish to elaborate, under the second and last heading mentioned.

With the equipment now at hand, it seems best to remove nearly all foreign bodies remaining in the tissues after gunshot as soon as conservatively possible. No discussion is entered into here about subsequent treatment, methods of irrigation, drainage tubes, bismuth iodoform petrolatum paste,[1] or types of dressings. Why should this prompt method be advocated and what are its limits?

It is commonly known that some foreign bodies, especially small ones, will remain in well vascularized, tissues, become encapsulated and cause no harm. That is a fact. On the other hand, take a half million instances of gunshot wounds. Without being able to give any reliable statistics, one may believe that a large proportion of them go on to suppuration, to indications for removal of the foreign body for that reason alone, or for pain or functional interference.

Suppuration, drainage, convalescence, late secondary operations after return to service, with all the handling and expense incident thereto, are a drag on resources. Could not an appreciable portion of this outlay be curtailed by prompt removal of foreign bodies? Because wounded men are rapidly conveyed to casualty clearing stations, there foreign bodies should be removed — with restrictions — so that the wounded may then, within a few hours for the most part, be on the first step to recovery. If suppuration follows, its course is shorter — the foreign body is out. There is far less likelihood of serious gas or other infection. More lives are saved. Time, dressings, the number of the medical corps assistants, transportation expense and home hospitals are curtailed, and a larger proportion of wounded men can be retained near the active field forces and sent back without home travel. One need only enumerate various complications which might be partly obviated. Long draining, secondary sinuses from tissues — foreign bodies lying within — secondary hemorrhages, and finally the psychologic effect on men who carry in their bodies these retained pieces of metal are avoided.

Let me cite some of the incidents of a day's work:

The first man had been shot sixteen months before, a small piece of shell entering the anterior aspect of the thigh. The foreign body had been located by means of the Roentgen ray, and was known to be present; but because it lay deeply near the femur and was small, causing no suppuration, removal was never attempted. The patient had worried so much about this that he finally had to be sent down to the base, complaining of great pain in the foot and the leg. I removed the body, cleanly encapsulated just in front of the femur. Great satisfaction and relief of all symptoms followed.

A second man was shot through the deltoid region. He had no marked symptoms, no bone, blood vessel or nerve injury, and was immediately sent on to the base with a dressing. In twenty-four hours a gas infection developed, and in spite of amputation, death followed quickly. Possibly extraction and drainage at the time of reception in the casualty clearing station would have saved his life.

Another instance of gunshot penetration of the knee joint may be cited. It had a small wound of entrance. Exploration arthrotomy was performed as soon as the patient was received. The joint was found transversed, was washed out with saline solution, and after removal of the foreign body the synovial membrane was closed snugly. The external wound was trimmed and sutured, and a small drain inserted to the closed capsule. Splint and extension were applied. Recovery followed with a useful knee joint.

---

[1] This is a paste much in vogue at the present time for smearing into wounds, followed by tight closure. It is sometimes referred to in English literature as bismuth iodoform paraffin paste, or B. I. P. P. Hence "bipp" and the verb "bipped."

Why should not all gunshot wounds be thus treated? Some cannot be, of course. Loss of blood, shock, anatomic inaccessibility, and perhaps a rush of work forbid. The first three named reasons may be adequate — the last not.

In all instances of gunshot injury with retained sizable missiles except those to be classed with complications of loss of blood, shock (anesthetic contraindication) and anatomic inaccessibility, it is suggested, because of the reasons outlined, that prompt removal be adopted.

THE VENEREAL DISEASES

BALANITIS GANGRENOSA

EROSIVE OR GANGRENOUS BALANITIS

(Continued from page 1005)

OTE.—*This is the third of a series of four articles on the agement of venereal diseases with special reference to ary practice. The first article on "The Diagnosis and reatment of Syphilis" appeared September 15, p. 907. The second article on "Chancroid" appeared September 22, p. 1004. The articles have been prepared under the direction of the Surgeon-General by the Advisory Committee on Venereal Diseases, Dr. William Allen Pusey, Chicago, chairman; Dr. Francis R. Hagner, Washington, D. C.; Dr. Grover W. Wende, Buffalo, Dr. Sigmund Pollitzer, New York, and Dr. Henry H. Morton, Brooklyn, with Lieut.-Col. F. F. Russell in charge of Infectious Diseases. The series is published with the permission of the Surgeon-General, and will include the following: Treatment of Syphilis; Chancroid; Balanitis Gangrenosa; Acute and Chronic Gonorrhea, with its complications. The complete series will be issued in the form of a manual.*—Ed.

In connection with chancroid attention is called to this venereal infection, which while rare is important, because of its destructive course, if unrecognized and treated as chancroid.

Balanitis gangrenosa begins as small whitish patches of superficial ulceration which are situated either in the coronary sulcus or on adjacent parts of the glans or prepuce. These excoriations increase in size and produce superficial, small, round ulcers which from coalescence form larger circinate ulcers. These ulcers are covered by a closely adherent necrotic pellicle, and are surrounded by an inflammatory border. The base of the ulcer bleeds readily when the pellicle is detached. The disease invariably occurs under a long prepuce, and when the process becomes well established the prepuce becomes edematous and phimosis usually occurs. There is a free discharge of very offensive thin, yellowish or brownish pus. This superficial form of the disease may get well spontaneously or as the result of treatment, but it is likely to develop into the gangrenous form. An intense edema of the penis develops and a black slough forms in the affected area. If the ulcer is situated on the prepuce, the dark area becomes visible from without. The slough perforates the prepuce and the glans often projects through the opening thus made. If the ulcer is on the glans itself, rapid destruction of it takes place. The whole glans may be destroyed in a few days. Following this, the gangrene spreads to the shaft of the penis, and partial or complete amputation may result. With the gangrenous form the discharge is yellowish or brownish, and is more offensive than in the less severe affection.

In both the erosive and gangrenous forms there is lymphangitis and enlargement of the inguinal glands, but, unlike the course of chancroid, the glands do not suppurate. In both erosive and gangrenous balanitis the parts are extremely tender. Urination is not painful unless the phimosis is such that, in urinating, the urine is dammed back and distends the prepuce.

In erosive balanitis systemic symptoms are trivial or absent. In the gangrenous form there is some sepsis, but in view of the intensity of the infective process it is usually comparatively slight. The patients are indisposed and have slight fever. Occasionally the symptoms are acute, with the temperature reaching 103 or 104 degrees.

ETIOLOGY

The disease is an infection caused by a symbiosis of organisms identical with those found in Vincent's angina and noma. Matzenauer contends that the same infection also produces hospital gangrene. Tunnicliffe, from her studies of Vincent's angina, believes that the spirillum and the vibrio are different forms of the same organism, and that the infection is not a symbiosis, but is due to one organism which under different conditions shows different forms.

The vibriones occur as curved rods with pointed ends, and are about 2 microns long and 0.8 of a micron in diameter. They stain with most dyes and are gram-positive if declorization is carefully done with 70 per cent. alcohol. The spirilla have loose, wavy spirals, and are 6 to 30 microns long, and 0.2 of a micron broad. They travel rapidly by quick back and forward snake-like motions. They are gram-negative, stain with most dyes, but are best examined under the dark field illuminator. The vibriones may be cultivated on serum agar. They are anaerobic, and in the lesions occur abundantly in the deeper part of the necrotic tissue. The spirilla are less abundant and are found more superficially in the lesions. Both are demonstrable in the tissues of the lesion, in the neighboring affected glands, and in the blood vessels.

The organism in the spirillar form occurs as a saprophyte in the mouth. It is only pathogenic when vibriones are also present and under anaerobic conditions, or under conditions of greatly lowered resistance. On the penis it only causes infection when protected from the air by a long prepuce. The infection of the penis is believed to occur from saliva. The affection is a disease of the vagabond class, and it is not extremely rare in public venereal clinics.

DIAGNOSIS

The most characteristic features of the affections are: the presence at or near the corona of the erosive or gangrenous lesions; the peculiarly bad-smelling purulent discharge; the occurrence under a long foreskin; and the presence in the secretion of vibriones and spirilla. In the severe gangrenous cases the rapidly spreading gangrene is very characteristic. The lesions are usually mistaken for chancroids. In balanitis gangrenosa there is a more intense inflammatory reaction, more edema of the prepuce, and more marked phimosis than in chancroid. The indolent glands are enlarged, painless, and do not suppurate as they almost invariably do in chancroid under a long prepuce. In chancroid, vibriones and spirilla are absent.

The lesions do not resemble an uncontaminated chancre, but, as in chancroid, a mixed infection with syphilis may occur and be entirely masked. In the case of mixed infection, the *Spirochaeta pallida* can also be demonstrated in the secretion.

Early diagnosis is of great importance, for a delay in proper treatment for a few hours may mean extensive spread of gangrene.

TREATMENT

The essential fact in the treatment of the condition is to expose the lesions so that oxygen can reach them. Otherwise their spread cannot be controlled. The prepuce should be opened by a dorsal slit, so that the glans is completely uncovered. Then the parts should be kept clean by washing with dilute hydrogen peroxid solution. The best procedure is to keep the parts continually moist either with wet dressings or by continuous irrigation with dilute hydrogen peroxid solution. If this cannot be used, the parts should be frequently irrigated with a bland antiseptic solution and left exposed to the air without dressings. With the use of 2 per cent. hydrogen peroxid solution healing is rapid.

(To be continued)

New and Nonofficial Remedies

The following additional articles have been accepted as conforming to the rules of the Council on Pharmacy and Chemistry of the American Medical Association for admission to New and Nonofficial Remedies. A copy of the rules on which the Council bases its action will be sent on application. W. A. Puckner, Secretary.

DICHLORAMINE-T, ABBOTT.—Paratoluenesulphonedichloramide.—$CH_3.C_6H_4.SO_2NCl_2$.—The dichloramide of paratoluenesulphonic acid, $CH_3.C_6H_4.SO_2OH$.

Actions and Uses.—Dichloramine-T, Abbott is said to be a powerful germicide, acting much like the monochloramine chlorazene, but capable of being used in solution in eucalyptol and liquid petrolatum, thus insuring a gradual and sustained antiseptic action. As in the case of chlorazene, dichloramine-T, Abbott is said to act essentially like the hypochlorites, but to be less irritating to tissues. Dichloramine-T, Abbott should not be administered internally.

Dichloramine-T, Abbott is claimed to be useful in the prevention and treatment of diseases of the nose and throat; it has been used with success as an application to wounds.

Dosage.—Dichloramine-T, Abbott, dissolved in chlorinated eucalyptol-Dakin and chlorinated paraffin oil-Dakin (which see), is used in concentrations of 2 to 10 per cent. When used as a spray a 10 per cent. solution of dichloramine-T, Abbott, in chlorinated eucalyptol-Dakin, is mixed with four times its volume of chlorinated paraffin oil-Dakin. For application to infected wounds a 10 to 15 per cent. solution of dichloramine-T, Abbott, in chlorinated eucalyptol-Dakin, is mixed with one-half to twice its volume of chlorinated paraffin oil-Dakin. (The solution of dichloramine-T, Abbott in eucalyptol is fairly stable, but the dilutions of this with chlorinated paraffin oil-Dakin should be prepared freshly when wanted.)

Manufactured by the Abbott Laboratories, Chicago. No U. S. patent or trademark.

Paratoluenesulphonedichloramide was introduced into medicine by H. D. Dakin and co-workers under the name "Dichloramine-T." It is prepared by chlorinating paratoluenesulphoneamide with subsequent purification (Journal A. M. A., July 7, 1917, p. 27).

Dichloramine-T, Abbott is a pale yellowish crystalline powder, having a strong chlorous odor. It melts at 78 to 83 C. It is insoluble in water, soluble in chloroform and benzene, soluble with difficulty in petroleum ether, slightly soluble in liquid petrolatum and soluble in eucalyptol.

Strong mineral acids liberate chlorine from dichloramine-T, Abbott. It reacts with most substances, such as acids, alcohol, hydrogen peroxide, amines, certain metals, etc. It liberates bromine from bromides and iodine from iodides in neutral solutions.

If 15 Cc. of a saturated aqueous solution of anilin is treated with 0.05 Gm. of dichloramine-T., Abbott, the solution acquires a brownish-red color, which becomes deep blue upon supersaturation with ammonia water.

Two Gm. of dichloramine-T, Abbott are treated with 10 to 15 Cc. of concentrated hydrochloric acid and heated to dryness. The residue is dissolved in a mixture of 1 part alcohol to 1 part water, and an excess of sodium carbonate added. The alcohol is removed by evaporation, and the cooled solution (with considerable insoluble material) is placed in a separating funnel and shaken with chloroform. The chloroform is drawn off, evaporated, the residue dissolved in smallest amount of cold chloroform, and then treated with an excess of petroleum ether. A white precipitate is formed, which, after drying, melts at 134 to 136 C. (Pure paratoluenesulphoneamide melts at 137 C.)

If 0.1 Gm. of dichloramine-T, Abbott is treated with a few drops of sulphuric acid, chlorine is evolved but no blackening occurs (readily carbonizable matter).

One Gm. of potassium iodide is dissolved in about 20 Cc. of glacial acetic acid, and any iodine set free is reduced by the careful addition of sodium thiosulphate solution. About 0.1 Gm. of dichloramine-T, Abbott (accurately weighed) is then added and titrated with tenth-normal volumetric sodium thiosulphate solution. The available chlorine content should not be higher than 31 per cent. or lower than 28 per cent. Each Cc. of thiosulphate solution is equivalent to 0.0177 Gm. of chlorine.

CHLORINATED EUCALYPTOL-DAKIN.—Eucalyptol, chlorinated at ordinary (room) temperature.

Actions and Uses.—Chlorinated eucalyptol-Dakin is used as a solvent for dichloramine-T.

Dosage.—Solutions of dichloramine-T in chlorinated eucalyptol-Dakin should preferably be made as required and without the use of heat. If kept in the dark, stock solutions may be used for thirty days.

Prepared by the Abbott Laboratories, Chicago. No U. S. patent or trademark.

Eucalyptol is treated with potassium chlorate and strong hydrochloric acid. After standing twelve hours at room temperature, the eucalyptol is washed, first with water and then with sodium carbonate solution. Dry sodium carbonate is then added to the chlorinated eucalyptol and this allowed to stand for twenty-four hours. The chlorinated eucalyptol is filtered and dried by addition of calcium chloride (Jour. A. M. A., July 7, 1917).

Chlorinated eucalyptol has the color and odor of eucalyptol.

CHLORINATED PARAFFIN OIL-DAKIN.—Liquid petrolatum, chlorinated at ordinary (room) temperature.

Actions and Uses.—Chlorinated paraffin oil-Dakin is used as a diluent for solutions of dichloramine-T, in chlorinated eucalyptol-Dakin.

Dosage.—Solutions of dichloramine-T in chlorinated eucalyptol-Dakin and chlorinated paraffin oil-Dakin are unstable, and should not be over four days old. In any instance they should be discarded as soon as a distinct precipitate appears.

Prepared by the Abbott Laboratories, Chicago. No U. S. patent or trademark.

Liquid petrolatum is treated at room temperature with potassium chlorate and strong hydrochloric acid, exposed to bright day light and allowed to stand over night. The chlorinated product is then washed with water, sodium carbonate solution and the oil drawn off, shaken with calcium chloride and charcoal and filtered (Jour. A. M. A., July 7, 1917).

Chlorinated paraffin oil-Dakin has the general physical properties of liquid petrolatum.

HYCLORITE.—A solution of chlorinated soda, each 100 Gm. of which is stated to contain sodium hypochlorite 4.05 Gm., sodium chloride 3.20 Gm., calcium hydroxide 0.25 Gm., inert salts 0.92 Gm. It contains not less than 3.85 per cent. available chlorine.

Actions and Uses.—Hyclorite has the action and uses of solution of chlorinated soda, U. S. P., but its available chlorine content is greater. One volume of hyclorite diluted with 7 volumes of water has the same available chlorine content as neutral solution of chlorinated soda, and is isotonic.

Dosage.—Hyclorite is used full strength or diluted with 1 or 2 parts of water for direct application to mucous membrane, muscular tissue, bone infections, etc. For irrigation of wounds, throat and body cavities dilutions of 1:100 to 1:1,000 are used. For use in the irrigation method of treating infected wounds dilute 1 part of hyclorite with 7 parts of water.

The available chlorine content of hyclorite decreases at the rate of about 12 per cent. per year. In order that due allowance for this decrease may be made when diluting for use, each bottle of hyclorite bears the date of bottling.

Manufactured by the General Laboratories, Madison, Wis. No U. S. patent. U. S. trademark applied for.

Hyclorite is prepared by decomposing chlorinated lime suspended in water with sodium carbonate and adding to the solution obtained, a freshly prepared solution of electrolyzed sodium chloride.

Hyclorite has the properties of solution of chlorinated soda, U. S. P., but contains no carbonate. When exposed to air a pellicle forms on its surface due to the formation of calcium carbonate.

About 10 Gm. hyclorite are weighed and transferred to a dish with about 100 Cc. of water and an excess of pure ammonium hydroxide solution is added. After about one-half hour the solution is evaporated to complete dryness on a water bath. To the residue is added about 50 Cc. of water, 2 drops of methyl orange test solution and an excess (measured) of tenth-normal hydrochloric acid volumetric solution and then the residual acidity determined by titration with tenth-normal sodium hydroxide volumetric solution. The alkalinity found corresponds to not more than 0.25 Gm. calcium hydroxide per 100 Gm. of hyclorite. Each Cc. of tenth-normal hydrochloric acid volumetric solution consumed corresponds to 0.0037 Gm. $Ca(OH)_2$.

Mix in a flask about 5 Cc. of hyclorite, accurately weighed, with 50 Cc. of distilled water, add 1 Gm. of potassium iodide and 5 Cc. of acetic acid and titrate with tenth-normal sodium thiosulphate volumetric solution, starch test solution being used as indicator. It shows not less than 3.85 per cent. available chlorine.

Each Cc. of tenth-normal sodium thiosulphate volumetric solution used corresponds to 0.003546 Gm. of available chlorine. Due allowance should be made for the decrease in available chlorine content of about 12 per cent. per year, date of bottling being stamped on each bottle.

with this widely used insecticide.[1] In the case of apples, the report points out, the maximum amount of the poison that may be expected to occur on the fruit in the ordinary course of events would not exceed 0.5 mgm. per apple. However, as much as 5 mgm. has been found on the surface of an apple after direct spraying with the poison. It is pointed out that such fruit would surely attract attention and in picking and handling would lose a material part of this residue, even if no rains intervened. It is believed, therefore, that under ordinary conditions no apples will reach the consumer carrying such amounts of arsenate of lead per fruit that a healthy human adult can eat enough at one time to cause fatal poisoning. Nevertheless experiments by Carlson and Woelfel at the University of Chicago have shown that lead arsenate, used as an insecticide or spray on fruit trees, is sufficiently soluble in human gastric juice to cause lead and arsenic poisoning. Measures must, therefore, be taken to remove this spray from the fruit. As Carlson has written, from the standpoint of public health rather than of the toxicologist, the question is not how much of the poison may be ingested without producing acute or obvious chronic symptoms, but how completely man can be safeguarded against even traces of the poison. Even extremely small doses of protoplasmic poisons when repeated may gradually produce deterioration and disease.

In the case of small fruits, such as the berries, the possibility of danger is even greater. In the case of the strawberry, to cite an instance investigated in New Hampshire, the surface of the fruit is of such a nature that larger amounts of the poison may be retained and quite possibly may escape notice. These residues also would be less likely to be rubbed off in handling and probably would wash off less rapidly. One portion of strawberries, consisting of one-fourth quart of the berries, may carry as much as 8 mg. of oxid of arsenic. This would probably seldom or never constitute a dangerous dose for an adult person in good health, but it might for a child or for an adult in weakened condition. It seems imperative, therefore, that strawberries fully formed or nearly so should not be directly sprayed with arsenate of lead, unless they are to be thoroughly scrubbed before using. Similar conclusions apply to currants, blackberries and other "small fruits."

The green vegetables which often require treatment by spraying are likewise not exempt from some degree of menace. A whole head of cabbage and lettuce directly sprayed and used without removal of outer leaves, may carry a relatively large amount of the poison. We are told that arsenate of lead should be applied only lightly and sparingly to cabbage or to lettuce that is ready for market. If these vegetables are sprayed the outer leaves should be removed and the heads should then be washed. If this is done, it is believed that there is no danger that these vegetables will carry to the table an amount of arsenic involving a dangerous dose for a human being. The well known experiences of cumulative effects with metallic poisons of the type here discussed, make timely a word of caution in view of the growing necessity for spraying as a procedure in the conservation of many edible products.

LARREY, THE ORIGINATOR OF RAPID EVACUATION OF THE WOUNDED

When Napoleon wrote in his will: "I leave 100,000 francs to Larrey—the most virtuous man I have known," he meant not only probity and honor, but virtue in the Roman sense. Larrey, the soldier, was the dutiful, reliable, courageous man of Roman type; Larrey, the physician, was the big human personality of large benevolent impulses, the kind of medical officer who actually carried a wounded soldier on his back in emergency. He was the generous, warm-blooded meridional, who came up to Paris from the Pyrenees, the type of Frenchman depicted in the canvasses of Ingres and David d'Angers. No French army surgeon has been so well beloved by his comrades since Ambroise Paré. He was one of the brilliant group of military surgeons whom Napoleon knew so well how to gather around him—Larrey, Percy, Desgenettes, a memorable trio. Larrey's system of movable field hospitals or flying ambulances (*ambulances volantes*) was introduced in September, 1792, when, as aide-surgeon-major of the French Army of the Rhine, he made the suggestion to General Custine, a suggestion as fraught with consequences as that of the Earl of Stair (or Pringle) at the battle of Dettingen. It created real first aid and rapid evacuation of the wounded from the battlefield, which is now the chief end of medical administration in campaign. It undoubtely served as a model for Letterman when he devised his improved system of ambulance and field hospital service for the Army of the Potomac in 1863. It was immediately followed by Baron Percy's innovation of telling off and training soldiers as field litter-bearers, to pick up the wounded in the progress of a battle and carry them on stretchers to a first aid station. To quote Larrey's[1] own words:

> My proposition was accepted, and I was authorized to organize this movable field hospital, which I named the flying ambulance (*ambulance volante*). I then conceived the idea of a system of carriages (*voitures d'ambulançe*) suspended on springs, which should combine solidity with speed and lightness. This institution created a sensation among the soldiers; they now all felt confident that they would receive succor at whatever moment they might be wounded!

This, and the centric idea which went with it—that the combatant forces are to feel in action that medical men are with them, that the wounded will be removed to places of safety as rapidly as possible—is Larrey's greatest achievement. But he did a host of other important things.

[1] Larrey: Mémoires de chirurgie militaire, Paris, I, 64.

He was an opponent of meddlesome surgery, which, in his day, was as pestiferous a nuisance as meddlesome midwifery; he believed in leaving simple wounds alone to heal of themselves. He washed wounds with a simple saline solution, and employed the powerful antiseptic, Labarraque's solution, in putrid and sloughing wounds (Da Costa). In place of the fierce purging and bleeding of his time, he fed the wounded a rich diet, even using a laryngeal tube or a nasal catheter for artificial feeding in wounds about the jaws and neck. His method of dressing wounds, cleansing away of débris, trimming of dead tissue and saturation with moist loose bandages, has some present day features. He showed the imperative necessity of drainage in large wounds, head injuries and pleural injuries, and insisted that all punctured wounds should be enlarged by incision and drained. He substituted immediate amputation for the secondary operation then common, but employed conservative resection when he could avoid amputation. He was ahead of his time in his knowledge of the symptoms of brain injuries, and discovered what is now known as Battles' sign—the discoloration over the mastoid process after fracture of the base.[2] In 1802, while in Egypt, he published at Cairo, his account of Egyptian ophthalmia or granular conjunctivitis, a disease which is mentioned and prescribed for in the Ebers Papyrus,[3] but which had remained unnoticed for some 3,400 years, until Larrey saw it. He was the first to point out the contagious nature of this disease, which is the outstanding feature of his historic monograph, and now a point of greatest importance to our immigration inspectors, who pass on the conjunctivae of Levantines and Orientals coming into the port of New York.

Such was the remarkable man who died seventy-five years ago and whose life is recorded elsewhere in our columns[4]—one of the greatest names in the history of military medicine and one of the most honored names in France.

---

[2] For these details of Larrey's achievement, we are indebted to the admirable summary by Dr. J. C. Da Costa in Johns Hopkins Hospital Bull., Baltimore, 1906, **17**, 213-215.

Alarming Mortality Among Negroes.—An alarming mortality among the negroes of Baltimore is shown by the statistics in the health department. Since 1912 there have been 10,813 negro births in the city, while 12,982 have been claimed by death. Among the white race the figures show that during the same period 54,483 births were reported, while 38,889 died. Dr. Blake has made an investigation and found that more than 99 per cent. of all births were reported. Since 1912 there has been a gradual increase in the birth rate in Baltimore. In 1912, 9,387 babies were born; in 1913, 10,309; in 1914, 10,662; in 1915, 11,460, and in 1916, 12,662. The annual number of negro births during the same period has ranged from 2,011 in 1912 to 2,423 in 1916. The greatest number of deaths in any one year since 1912 among the whites occurred in 1916, when 7,983 persons died; the smallest number was 7,525. The average annual death rate among the negroes for the same period was approximately 2,500.

Current Comment

THE OPERATION ON PRESIDENT CLEVELAND

Last week's issue of the *Saturday Evening Post* has a most readable account by Dr. W. W. Keen of Philadelphia of the operation that was performed on President Cleveland twenty-four years ago—in 1893—soon after the president entered on his second administration. The operation, which was performed on a private yacht, was for sarcoma of the jaw. It was quite extensive; a rather large part of the bone was removed; and yet there was rapid recovery and few knew that an operation had been performed. The late Dr. Joseph D. Bryant, who was President Cleveland's physician, performed the operation, Drs. Keen, E. G. Janeway and John F. Erdmann assisting. While the article is not of particular scientific or surgical importance historically, it is of decided interest. Dr. Keen emphasizes the critical financial and political conditions that prevailed at the time and shows how it was absolutely necessary that the dangerous condition of the president should not be made known. It is remarkable that a quarter of a century elapsed before this historically important occurrence was made public.

THE TREATMENT OF ANTHRAX WITH NORMAL SERUM

Human anthrax is increasing steadily and of late rather sharply in this country. It is coming to be recognized by students of industrial conditions as an important occupational disease. As such it must be guarded against with especial care in these days when it is so essential to maintain satisfactory conditions throughout the whole industrial organization. The resistance of anthrax spores to drying and other influences renders the disease difficult to eradicate when once it gets a foothold. Until more stringent measures for the disinfection of hides, wool and similar animal products imported from anthrax infected regions are put in force, a further increase in cases may be anticipated. The case mortality from anthrax, while high, is not as great as is sometimes stated. In the most carefully reported series it seems to range from 13 to 24 per cent., the difference being probably due in part to variations in the extent of diagnosis and in part to inclusion of mild cases. The specific anti-anthrax serum produced by Sclavo is said to have lowered the mortality rate considerably, its use in 164 cases being accompanied by a death rate of 6 per cent., as contrasted with a rate of 24 per cent. in Italy generally. Sclavo's serum has not come into common use in spite of the considerable degree of success that has attended its introduction. One reason may be that the preparation and marketing of the serum seem to entail a high expense, the cost of the initial dose running as high as thirty dollars or more. The country of Argentine with its great cattle-raising industries has suffered more severely from anthrax in recent years than any other part of the world, and it is appropriate that a new and interesting method of treatment should be proposed by R. Kraus, head of the bacteriologic institute of the national department of health of that country.[1] The method, although its theoretical interpretation presents some difficulties, is simplicity itself in practice. It consists in the inoculation, usually intravenously, of normal bovine serum in quantities of 20 to 30 cubic centimeters or more. Intramuscular and subcutaneous injections are said to have given results substantially as satisfactory as the intravenous injections. The serum is heated twice for half an hour at 56 degrees C. before injection. In the report cited it is stated that fifty cases of bacteriologically verified anthrax were treated by this method without a single death. We understand that since this report was published the number of cases treated by Kraus with normal serum has risen to over ninety with but one death. These results are more favorable than those reported from the use of the specific antiserum.

RABBIT-FOOT THERAPY

Few but ignorant darkies have any great faith in the therapeutic efficacy of the left hind foot of a rabbit caught in the churchyard in the dark of the moon. In the light of modern therapeutics one is tempted to believe, however, that had some one person or firm an exclusive proprietary right to this particular brand of rabbits' feet, there would be many intelligent people—and not all of them laymen—ready to swear by rabbit's foot therapy. In medical journals (whose advertising pages set forth the virtues of the pedal extremities of *Lepus sylvaticus*) many solemnly scientific articles would probably appear relating the success that the writers had had with this form of therapy in the treatment of some distressingly stubborn conditions that had failed to respond to all previous efforts. Is it ubiquity that has saved the homely cotton-tail from being a therapeutic hero?

UNIVERSITY OF TEXAS FREED FROM POLITICS

Three months ago reference was made[1] to the attempt by the governor of Texas to secure political control of the University of Texas and its medical department. That attempt aroused a vigorous protest throughout the state. At a special session of the legislature, articles of impeachment were filed and Governor Ferguson was suspended; an appropriation of $1,629,407.17 for the university, including $197,500 for the medical department, which Governor Ferguson had vetoed, was again passed, and three regents of the university named by Governor Ferguson were replaced by those who have the best interests of the university at heart. Ten of the twenty-one charges in the bill for impeachment are now reported to have been returned against Governor Ferguson. Among these charges were his efforts "to coerce and influence the Board of Regents of the University of Texas" and "that he sought to violate the law by removing regents without adequate cause." This vigorous action by the Texas legislature, following the attempt of its state executive to convert the state university into a part of his political machine, will have a deterring effect on further attempts in a similar direction.

Medical Mobilization and the War

NEWS OF THE BASE HOSPITALS

Base Hospital No. 3, Mount Sinai Hospital, New York, has been mobilized, and is expecting orders for duty abroad. The medical personnel includes Major M. A. Dailey, M. C., U. S. Army, commanding officer; Capt. William A. Schwab, quartermaster, and the following officers of the Medical Reserve Corps: director (chief of medical service), Major Nathan E. Brill; assistant director (medicine), Capt. Louis Hauswirth; physicians, Capts. Herbert L. Celler, Edwin Sternberger; Lieuts. Daniel Poll, Herbert Emsheimer, Joseph Rosenfeld, Nathan Rosenthal, and A. S. Kversky, neurologist; assistant director (laboratory), Major George Baehr and Lieut. Bernard S. Denzer; assistant director (Roentgen ray), Capt. Leopold Jachss; assistant director (chief of surgical service), Major Howard Lilienthal; surgeons, Capts. Edwin Beer, Walter M. Brickner, Robert T. Frank, Leo B. Mayer, Sidney Cohen, Ira Cohen, S. H. Geist; Lieuts. Alfred Braun, E. Bleier, registrar, and dentists, Lieuts. Jacob Asch and Louis Stern.

Base Hospital No. 23, Buffalo, is now mobilized at Fort Porter, N. Y., under the command of Major G. V. Rukke, M. C., U. S. Army, and is awaiting orders to embark for overseas service. The following is a list of the medical personnel: director, Major Marshall Clinton; registrar, Mr. E. J. Fairbairn, civilian employee; adjutant, Lieut. Timothy F. Donovan; quartermaster, Capt. J. H. Hickey; mess officer, Lieut. H. C. McDowell; commanding officer detach. medical department, Major N. G. Russell; chief surgical service, Major Marshall Clinton; chief medical service, Major N. G. Russell; pathologist, Capt. J. B. Betts; assistant pathologist, Lieut. R. N. De Niord; dental surgeons, Lieuts. C. L. Storms and E. J. Knoche. Ward officers: surgical—Capts. H. A. Smith, F. W. McGuire, J. P. Brennan, D. C. McKenney, L. Burrows; Major J. F. Fairbairn and Lieuts. W. L. Machemer and H. C. Fairbanks. Medical—Capts. F. P. Goodwin, R. E. DeCeu, Baldwin Mann, and Lieuts. H. C. McDowell, J. A. P. Millet, H. F. May and H. K. Hardy.

Base Hospital No. 27, University of Pittsburgh Medical School, has been mobilized at Allentown, Pa.

Base Hospital No. 31, of the Youngstown (Ohio) Hospital has been mobilized at Allentown, Pa., under command of Major Adam E. Schlanser, M. C., U. S. Army, and is awaiting orders for service abroad. The personnel includes: Drs. C. R. Clark, director and chief of medical service; James A. Sherbondy, assistant director and chief of surgical service; B. W. Wilson, first assistant, medical service; C. C. Wolferth, chief of laboratory; S. M. McCurdy, registrar; M. P. Jones, first assistant, surgical service; A. E. Brant, staff surgeon and urologist; J. U. Buchanan, D. A. Nesbitt, E. R. Thomas, C. H. Moses, W. K. Allsop, staff surgeons; J .L. Washburn, ophthalmologist; F. J. Bierkamp, rhinologist and laryngologist; R. R. Morrall, orthopedic surgeon; P. G. Bordon, neurologist; D. B. Phillips, C. D. Barrett, R. W. Fenton, W. H. Bunn, staff physicians; O. D. Hudnut, roentgenologist; C. M. Reed, pathologist; F. W. Ward, W. H. McCreary, dentists.

Base Hospital No. 32, Indianapolis, was mobilized, September 1, at Fort Benjamin Harrison, Ind., under command of Major Harry R. Beery, M. C., U. S. Army. Following is a list of the medical personnel: director, Major Edmund Dugan Clark; Majors Orange Garrett Pfaff and Bernays Kennedy; Capts. Carleton Buel McCulloch, Alois Bachman Graham, Charles Dolph Humes, Eugene Bishop Mumford, Lafayette Page, Harry F. Byrnes and Joseph Kent Worthington; Lieuts. Scott Robert Edwards, Ralph Landis Lochary, Raymond Cole Beeler, Robert Martin Moore, Leslie H. Maxwell, Paul Thomas Hurt, Smith Quimby, Ralph Lincoln Sweet, John Thomas Day, Joseph Warren Ricketts, Frank Columbia Walker, Jack Walter Scherer and James Vincent Sparks. The last two officers are dentists.

Base Hospital No. 34, attached to the Episcopal Hospital, Philadelphia, was called into active service, September 14, at Allentown, Pa. Following is a list of the medical personnel: Majors Ralph G. Devoe, Astley P. C. Ashhurst, Emory G. Alexander, John B. Carson; Capts. Ralph S. Bromer, R. I. Levin, John W. Moore, Henry G. Welker; Lieuts. Benjamin F. Buzby, Irvine M. Boykin, Royeal E. Durham, John S. Eynon, Lewis W. Frank, Rutherford L. John, John Paul Jone, John D. Paul, Raymond J. Sprowl, George Wilson, Karl D. Winter and John B. Wolfe; also Lieuts. George A. Coleman and Faver W. Croll of the dental section of the M. O. R. C.

Base Hospital No. 36, Detroit, has been mobilized at the State Fair Grounds.

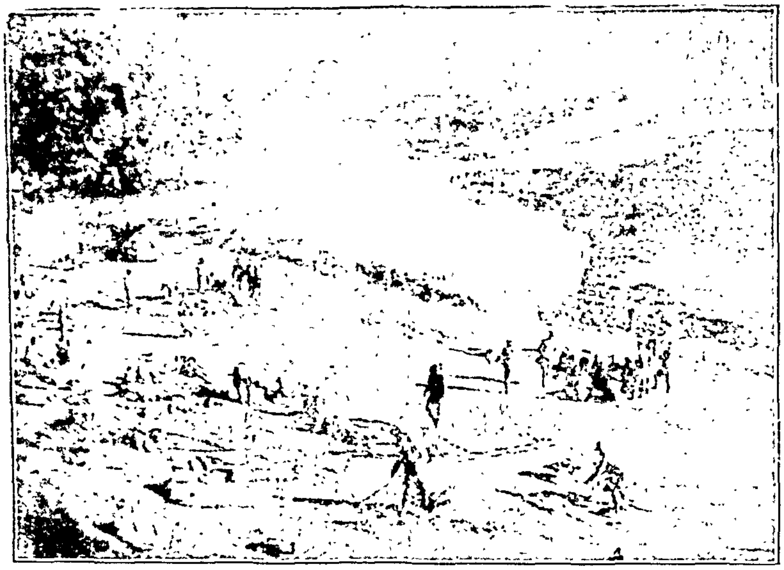
Members of Naval Base Hospital No. 5, recruited at the Methodist Hospital, Philadelphia, were ordered to report, September 12, to the Navy Yard in that city, for duty, and sailed, September 17, for France. This unit is under the directorship of Dr. Robert G. LeConte, Philadelphia. The members of Lieut.-Col. LeConte's staff are: Lieuts. William Hewson, J. Leon Herman, J. H. A. Cleaver and George E. Darby, Bella Bella, B. C. The officers of the unit are: assistant director, Lieut.-Com. James E. Talley, Lieuts. George G. Ross, B. B. Vincent Lyon, Grayson P. McCooch, Percival M. Kerr, Elwyn, and John A. Hugo.

NEWS OF THE TRAINING CAMPS

At Fort Benjamin Harrison

TRENCH WARFARE

The past week has been comparatively uneventful. There has, however, been one outstanding novelty in the week's program, in the assignment of details from each company for duty in the trenches. These have been dug by members of the Officers' Training Camp under the supervision of Lieutenant Haye of the French Army, and are most elaborate and realistic in construction. The trench details repair to their posts in the afternoon and prepare themselves for the night attack. When darkness comes on an opposing force attempts to take the trenches, to the accompaniment of sentry's challenges, illuminating rockets, and the other excitements of a night attack. After the attack the medical detail is supposed to go "over the top" with litters and collect the wounded, who are men previously detailed for the duty. They load them on the litters and carry them back to the regimental aid station in the trenches. The first night or two there was rain and mud in plenty, so that the elements did their best to help reproduce the conditions familiar in Flanders. The men came back to camp ready for a twenty-four hour sleep, some of them sheepishly confessing that they had been picked off by their own outposts, but all agreed that the experience was well worth the wounds and disability resulting from it.



The Bivouac at Fort Benjamin Harrison

REGULAR ARMY CANDIDATES

Candidates for the Regular Army Medical Corps who have taken their preliminary examinations have been grouped together in Companies 3 and 4, for the purpose of more intensive training and closer observation by the regular officers in charge. Some of them have already been detailed temporarily to ambulance companies and field hospitals, so as to give them the chance of studying the routine of these units at first hand. Major Darby, M. C., is conducting a most strenuous class in setting up exercises for their exclusive benefit, comprising body-rolls, somersaults, and other acrobatic feats.

LECTURES

There have been no lectures of importance during the week except for one by Major Bell of the Canadian Army on his experiences during nine months of trench warfare on the western front. Much of this time was devoted to answering questions, though his audience would have been delighted to hear him talk for an extra hour or more.

MEETING OF MILITARY SURGEONS

Colonel Ashburn announced to the assembled student officers that there is to be a meeting of the Association of Military Surgeons in Indianapolis on October 8 and the two following days. Some of the program was outlined, and the cooperation of every one was asked in making the meeting a roaring success. The country-wide fame of some of the expected visitors is of itself sufficient to make it a memorable occasion, and it is sincerely hoped that there will be a good turn-out of the profession to hear the speakers.

THE CAMP VIEW OF DRAFTING THE MEDICAL PROFESSION

Some animated discussion has been provoked in this camp by the appearance in the last issue of The Journal of a letter written by Major Richard Derby, M. R. C. He states that "a fair proportion of the physicians who have volunteered are men who have been attracted to a new life through a failure to succeed in their old," and again that "we have not obtained through the volunteer system the men best qualified for the important duty of caring for our sick and wounded." As applied to the personnel of this training camp, at least—and there is no evident reason why this camp should differ in this respect from the other Medical Officers' Training Camps in the country—such statements would seem, to say the least of it, distinctly unjustifiable. While it is true unfortunately that the average age is high, and that therefore there is evidently a lack of younger volunteers, the vast majority of the older men in training are men highly respected in their communities, who have made considerable sacrifices to follow what they considered to be the path of duty. Furthermore, if a comparison were drawn between the sum of those men who now hold commissions in the Medical Reserve Corps, or are continuing in civil life only because their services are more valuable to the country in their present capacity, and the sum of those who are taking no active part in the country's program of medical preparedness, who could then say that the pick of the country's physicians is not already in the country's service?

COMPANY NEWS AND PERSONAL

Major F. W. Loughran, M. R. C., assistant sanitary inspector, has left for New York on leave of absence.

Capt. R. M. Wilder has returned from his leave of absence, and is again at his desk in the Adjutant's Office.

Capt. Richard Weil ordered to the Rockefeller Institute.

The total strength of the training camp in medical officers alone is now 1,275.

Company 1 gave a banquet on Wednesday, September 19, at the University Club, Indianapolis, in honor of their chief instructor, Captain Celler. Eighty of the old members were present. The old company has been broken up and distributed among the other old companies. Many of the men are candidates for the regular corps. A new company has been formed this week, with Captain Celler still in command. He is to be assisted by Capt. S. J. Young and Lieuts. H. S. Osborne, V. C. von Unruh and Roy T. Morris. Lieutenant von Unruh has also been appointed assistant to Major Snyder in the teaching of equitation. The company is now under the direct supervision of Colonel Shockley, M. C.

Company 2 has lost Lieutenant Bayless from its corps of instructors. His place has been taken by Captain Stanton.

Company 7 has added Lientenant Hoyt to its instructing staff, by transfer from Company 1.

Company 8 has lost Major Caccini, its chief instructor. His place has been taken by Major Phillips.

Company 10 now has Major McCormack, M. C., in immediate command.

THE BIVOUAC

Several of the companies, through the kidness of Capt. F. Hutchins, Company 4, have had the privilege of enjoying a night's bivouac in the prettiest section of the surrounding country. During the day's trip the men were assigned problems in sanitary tactics, including choice of locations for ambulance companies, with their respective field dressing stations, and for the establishment of a field hospital, the disposition of the defending and attacking forces having been previously announced. The work is shown in the accompanying illustration.

FOR THE CONTROL OF VENEREAL DISEASES

At Jackson, Mich., September 12, a conference of men and women, prominent in business and professional life in the state, was held for the purpose of considering the menace of venereal diseases in relation to the public health. Dr. C. G. Parnall, health officer of Jackson, in explaining the purpose of the meeting said that any movement designed to attack the problem must take cognizance of two main features: the prevention of venereal diseases in the Army and the control of these diseases in the civil population. Addresses were made among others by Dr. W. H. Martin, associated with Major Snow, in charge of venereal disease work in the United States Army; Avery G. Clinger, stationed at Battle Creek Cantonment as head of the War Department Commission on training Camp Activities; Major Neil M. Wood, head of the base hospital at Camp Custer; Dr. A. S. Warthin, head of the department of pathology of the University of Michigan; Dr. J. H. Kellogg of Battle Creek and Dr. Richard Olin, secretary of the state board of health. A tentative program was outlined for the prevention of venereal diseases involving the following propositions:

PROGRAM FOR THE PREVENTION OF VENEREAL DISEASES

1. *Prostitution* is to be suppressed vigorously and continuously, through the enforcement of the State laws, and the issuance of certificates of health to prostitutes for use in soliciting is not to be included in this program.

2. Prostitutes brought to the attention of the police or health authorities are to be examined; and all persons, male or female, capable of spreading venereal disease are to be isolated, under the provisions of the public health act, or local ordinance, and treated at public expense as long as there is danger in the opinion of the health officer, of their *exposing others*.

3. Under no circumstances are infected prostitutes to be "floated" into other communities, and if they are known to go from one community *to another*, the health officials of the place of destination are to be notified at once.

4. The State law requiring the reporting of syphilis and gonococcus *infections* by physicians, office numbers, is to be enforced to the letter, and, in addition, physicians are to be urged to obtain and furnish to the local health officers the names of the persons who are suspected of *disseminating infection*. The local health officers are therefore to investigate and supervise or isolate infection cases according to the circumstances.

5. To provide and encourage the instruction of young men and women in the advantages of a clean life and the dangers from venereal disease.

6. To provide adequate opportunities for expert diagnosis, treatment and advice for infected persons financially unable to secure proper attention for themselves, and to encourage the *continuance of treatment* until the patient is cured, or at least becomes noninfectious.

7. To provide free laboratory tests for syphilis and gonococcus infections for *physicians, and to encourage* greater use of the tests for these diseases available at the laboratory of the Bureau of Communicable Diseases of the State Board of Health.

A permanent committee to carry on the work was appointed as follows: Dr. W. H. Sawyer, Hillsdale; Miss Eleanor Hutzell, Detroit; Rev. Caroline Bartlett Crane, Kalamazoo; Dr. A. S. Warthin, Ann Arbor; Fred L. Woodworth, state dairy and food commissioner, Lansing; Dr. C. G. Parnall, Jackson; Dr. R. M. Olin, secretary of the state board of health, Lansing; Rev. Charles D. Williams, Detroit, and Mr. James Couzens, Detroit.

By a resolution Governor Sleeper was asked to appoint a commission to make recommendations for the control of venereal diseases within the state. On this commission the governor later appointed the following: Drs. R. M. Olin, Lansing; W. H. Sawyer, Hillsdale; A. S. Warthin, Ann Arbor; C. G. Parnall, Jackson, and Guy L. Keifer, Detroit. This commission met with Governor Sleeper at Lansing, September 18. The chief features of the immediate program outlined at that meeting include the investigation of the source of the infection, the segregation and hospital treatment of all infected prostitutes and the development of hospitals for such treatment.

PUBLIC HEALTH SERVICE RESERVE CORPS

It is quite probable that Congress will enact a law providing a reserve corps for the Public Health Service, a subject already referred to in these columns. The original measure, a Senate Joint Resolution, which had the approval of the Public Health Service and the Treasury Department, passed the Senate and was referred to the Committee on Interstate and Foreign Commerce of the House. This committee has already reported, recommending the measure in the form of a bill; and while the committee has made some modifications they are not seriously in conflict with Senate's measure. The House substitute covers most of the essential features of the original measure as passed by the Senate, so that if it passes the House, which now seems extremely probable, it will undoubtedly be approved by the Senate.

The bill provides for a reserve corps to be composed of the officers of state, county and municipal health organizations, and other persons skilled in sanitary science. Such officers must make voluntary application to the Surgeon-General for appointment, and, with the assent of the proper executive officers of the respective states, counties and municipalities, may be commissioned with the grade of assistant surgeons, past assistant surgeons, surgeons, or senior surgeons in the Reserve Corps of the Public Health Service for four years, or during the war. Sanitary engineers, assistant sanitary engineers, epidemiologists and assistant epidemiologists on the recommendation of the Surgeon-General, may also be commissioned as such. The duties of the reserve corps shall be directed toward the proper sanitation of ports and places within the United States or within its jurisidiction, especially places in which or near which industrial and military forces are to be mobilized, in which the corps shall cooperate with local health organizations and officials in charge of industrial establishments. The bill provides for an elastic organization which may be immediately expanded, whereby the government can instantly attack civilian epidemics which threaten to spread to military forces, which permits sanitation under federal direction of areas in contiguity to military camps, augments existing agencies for the collection of morbidity reports, and brings into the service of the United States as an aid to military operations a body of highly trained sanitarians, engineers and epidemiologists who would otherwise be unavailable for military duty.

SURGEON-GENERAL'S OFFICE REQUESTS INFORMATION ON REHABILITATION OF THE INJURED

The Surgeon-General's Office has addressed a letter to the secretaries of all county medical societies relative to the rehabilitation of partially handicapped persons who have been successful following injury. Arrangements are being made for special treatment for the wounded, including special efforts for functional restoration of damaged parts and vocational reeducation for those who, from the nature of their illness or injury, are unable to follow their previous occupation.

INFORMATION REGARDING SUCCESSFUL CRIPPLES

To aid in this work the Surgeon-General desires to know what those who are suffering from chronic illnesses or who are partially disabled as a result of injuries, are now doing. For example, a person who has lost the right hand may still be a successful carpenter or market gardener; one having lost both lower extremities may be successful in some line in which he is not required to move from place to place; a man with chronic heart disease may be suitably occupied in work in which there is no special stress on that organ. The collection of this experience should be of remarkable assistance as showing what the various types can do.

The Surgeon-General requests that medical societies and physicians aid in this work by securing a list of partially disabled persons in the county who are successfully following trades or occupations. The information desired in reference to each case should include: (*a*) character of disability, medical or surgical; (*b*) the work at which the patient is employed, and degree of success; (*c*) the way in which he learned or entered his occupation after his injury or illness. The names of the disabled are *not* necessary.

If any man who has been successful after an injury or illness desires to write a short autobiography stating his experience, this will be very useful and will be utilized in preparing a booklet to be distributed to the men at the proper time.

EXEMPTION OF MEDICAL STUDENTS AND INTERNS

Provision for Permitting Medical Students Who Have Been Accepted for the Draft to Continue Their Professional Studies

In accordance with the supplemental regulations authorized by the President, the Surgeon-General of the Army has approved the following forms which are to be filled out and returned to him. This should be done without delay. It must be understood that medical students permitted to continue their studies under these provisions are not exempted and may be called to duty at any time that the President deems their services especially needed by the Army.

AFFIDAVIT OF DEAN AND STUDENT

The dean or secretary will make his affidavit and send it to the student accepted for the draft, who will make his affidavit and forward both affidavits with a copy of the order of the local board calling him to report for physical examination (Form 103), to the Surgeon-General of the Army, Washington, D. C. Affidavits must be executed by some one legally qualified to administer an oath.

AFFIDAVIT OF THE DEAN OR SECRETARY OF THE MEDICAL SCHOOL

I, ..., Dean of .... Medical School, do swear that the official records of this school show that .... entered this school ...., ..., and that he has successfully done the
Mo. Yr.
work of his class.

....

Date ....

Subscribed and sworn to before me this .... day of ...., A. D. 1917.

....

AFFIDAVIT OF THE STUDENT ACCEPTED FOR THE DRAFT

I, ..., having been accepted for the draft by local board .... am a student in ....
second
.... Medical School in the third year, having entered said
fourth
school ...., ...
Mo. Yr.

I hereby apply to the Surgeon-General of the Army to be ordered to report at once to my local board for military duty and thus to be inducted into the military service of the United States, immediately thereupon to be discharged from the National Army for the purpose of enlisting in the Enlisted Reserve Corps of the Medical Department. I have been called by local board ...., physically examined and accepted, and there is no claim for my exemption or discharge now pending and I have not been ordered to military duty. In compliance with the supplemental regulations governing the execution of the Selective Service Law authorized by the President and issued under date of August 29, 1917, I am making this application and am enclosing herewith a copy of the order of the local board calling me to report for a physical examination (Form 103).

I do hereby pledge myself to enlist in the Medical Enlisted Reserve Corps and to promptly respond either before or after my graduation on an order from the Surgeon-General to active duty.

....

Date ....

Subscribed and sworn to before me this .... day of ...., A. D. 1917.

....

AFFIDAVIT OF THE MEDICAL STUDENT WHO HAS BEEN ACCEPTED FOR THE DRAFT, AND IS NOW ON ACTIVE DUTY IN A CANTONMENT OF THE NATIONAL ARMY

I, ..., having been accepted for the draft by local board ...., am a student in
second
.... Medical School in the third year,
fourth
having entered said school ...., ...
Mo. Yr.

I hereby apply to the Surgeon General of the Army to be ordered to be discharged from the National Army for the purpose of enlisting in the Enlisted Medical Reserve Corps of the Medical Department. I have been called by local board ...., physically examined and accepted, and am now in active service in the National Army at Camp ...., located at ....,
City
.... In compliance with compiled rulings No. 11 of
State
Provost Marshal General, Part 1 (Z), I am making this application and am enclosing herewith a copy of the order of the local board calling me to report for a physical examination (Form 103).

I do hereby pledge myself to enlist immediately in the Medical Enlisted Reserve Corps and to promptly respond either before or after my graduation to an order from the Surgeon General to active duty.

Provision for Permitting Hospital Interns Who Have Been Accepted for the Draft to Temporarily Continue Their Professional Duties

In accordance with the supplemental regulations authorized by the President, the Surgeon-General of the Army presents the following form to be filled out and returned to him. This should be done without delay. It should be understood that hospital interns permitted to continue their hospital duties under these provisions are not exempted from the draft and may be called to duty at any time that the President deems their services especially needed by the Army. The spirit of the supplemental regulations issued by the President does not permit the recognition of an internship continuing more than twelve months.

The superintendent of the hospital will execute his affidavit, ask the drafted intern to fill out his and return both affidavits with a copy of the order of the local board calling him to report for physical examination (Form 103), to the Surgeon-General of the Army, Washington, D. C. Affidavits must be executed by some one legally qualified to administer an oath.

AFFIDAVIT OF THE SUPERINTENDENT OF THE HOSPITAL

I, ..., do swear that I am Superintendent of .... Hospital located at ...., ..., and that ....
City State
..............................., M.D., is a bona fide intern in this hospital, devoting his entire time to his intern work and receiving therefor no compensation; that I regard his continuance in this position as essential to the best interests of this hospital; that the daily average number of patients in this hospital is ...., and that the number of interns in this hospital is ....; that the drafted intern herein specified began his internship ....,
Month
........., ..., and it naturally terminates ....,
Day Year Month
................., ...
Day Year

....

Date ....

Subscribed and sworn to before me this .... day of ...., A. D. 1917.

....

AFFIDAVIT OF THE DRAFTED HOSPITAL INTERN

I, ..., having been accepted for the draft by local board .... am an intern in .... Hospital located at ...., ... I
City State
graduated from .... Medical School ...., ... I began my internship in this hospital
Mo. Yr.
...................., ..., ..., and my term of service
Mo. Day Yr.
expires ...., ..., ...
Mo. Day Yr.

I hereby apply to the Surgeon-General of the Army to be ordered to report* at once to my local board for military duty and thus to be inducted into the military service of the United States, immediately thereupon to be discharged from the National Army for the purpose of enlisting in the Enlisted Reserve Corps of the Medical Department. I have been called by local board ...., physically examined and accepted, and there is no claim for my exemption or discharge now pending and I have not been ordered to military duty. In compliance with the supplemental regulations governing the execution of the Selective Service Law authorized by the President and issued under date of August 29, 1917, I am making this application and am enclosing herewith a copy of the order of the local board calling me to report for a physical examination (Form 103).

I do hereby pledge myself to enlist in the Medical Enlisted Reserve Corps and to promptly respond at any time to an order from the Surgeon-General to active duty.

....

Date ....

Subscribed and sworn to before me this .... day of ...., A. D. 1917.

* This report may be made in person, by mail or by telegram.

Physicians Recommended for Commission in the Reserve Corps

During the week ending Sept. 22, 1917, 709 physicians were recommended for commission in the Medical Reserve Corps, the proportion being thirteen majors, eighty captains and 616 lieutenants.

Physicians Go to Join Staff of American Hospital in Paris

At the request of Dr. Joseph A. Blake, Dr. J. B. McCook of Hartford, Conn., and Dr. W. Irving Clark of Worcester, ss., will be sent to the American Red Cross Hospital in is.

Medical History of the War

Col. C. C. McCulloch, M. C., U. S. Army, and Major Fielding H. Garrison, M. R. C., U. S. Army, have been constituted a board to collect and prepare material for a medical and surgical history of the war.

Red Cross Commission to Russia Returns

The major portion of the Red Cross Commission to Russia is now in Japan on its way back to this country and is expected home about October 20. It is announced that Mr. Raymond Robins of Chicago is to remain in Russia and, in addition to his work as director of the Red Cross, will supervise the four principal relief organizations.

Statistics of the Dental Corps

The Surgeon-General's Office has completed the enrolment of, and now has at its disposal, 178 Dental Corps officers, 221 National Guard dental officers, and 2,473 Dental Reserve Corps officers, making a total of 2,872, or enough to supply in the proportion of one dentist to 1,000 men, as authorized by law, an army of 2,872,000 men. No more dental officers will, therefore, be required in the immediate future.

Doctors and Nurses Decorated

Justine Godart, undersecretary for the Army Medical Service, on September 15, visited the Chateau in the department of Yonne where the French Hospital of New York has conducted a military hospital of 250 beds since early in 1916. Decorations were conferred on Drs. John C. Irwin and Thomas M. Savage, and on nine of the nurses on duty in the institution.

Second Infant Welfare Unit Goes to France

The American Red Cross announces that Dr. Charles Ulysses Moore of Portland, Ore., has been sent to France to reenforce the Infant Welfare Unit now at work there under the direction of Dr. William P. Lucas of the University of California. With Dr. Moore will go sixteen nurses who have had special training in children's diseases and socal welfare work. A third detachment of physicians for this service is expected to sail shortly.

Red Cross Commission to Roumania Goes to Jassy

According to cable advices, the American Red Cross Commission to Roumania left Petrograd last week for Jassy. Conference with Ambassador Billings, minister to Roumania, revealed the fact that immediate supplies, including medical equipment of every kind are badly needed. Wounds are now being dressed with sawdust. An urgent need also exists for ambulance transports with drivers and machines. A typhus epidemic threatens for the winter.

Public Health Nurses to Work in Region of Cantonments

Fifty public health nurses have been assigned for duty by the American Red Cross to the zones around the various cantonments. Nurses have already taken up their work in the civil districts around the cantonments at Hattiesburg, Miss.; Fort Riley, Kan.; Des Moines, Iowa; Louisville, Ky.; Little Rock, Ark.; Ayer, Mass.; Chillicothe, Ohio; Atlanta, Ga.; Newport News and Petersburg, Va. These nurses will act as visiting nurses in the territory surrounding the camps and will endeavor to prevent the spread of tuberculosis, malaria and social diseases, and to strengthen the local infant welfare programs.

Appropriations for Sanitary Units

September 16, it was announced by the National Red Cross that appropriations had been made to assist local authorities in protecting health about Army camps as follows: for Newport News, Va., $21,000 was provided; $5,000 for three nurses to work with the Massachusetts Health Department at Ayer; $14,000 to Atlanta, Ga., chiefly for the destruction of malaria-bearing mosquitoes around Camp Gordon; $10,000 for Chillicothe, Ohio. In all $106,000 has been appropriated.

Germans Agree Not to Attack Hospital Ships

A dispatch to Paris from Madrid states that King Alfonso has obtained from the belligerent powers an agreement permitting the free movement of French and British hospital ships in the Mediterranean and the Atlantic as far as the English Channel. This agreement also provides for the removal from French hospital ships of German officers who have been held prisoners thereon, and the removal of French prisoners from exposed positions on the war front.

Sanitary Unit Established

P. A. Surg. Joseph R. Ridlon, U. S. P. H. S., has announced that a provisional allotment of $10,000 has been made for the sanitary unit of the American Red Cross at Anniston, Ala., and the unit has been established with Emmett W. Ledbetter as business manager and Dr. Ridlon as director. Work has already been begun at the task of making mosquito-proof the area adjoining Camp McClellan. A laboratory will be established in Anniston which may be used by any physician in the city or county for the examination of specimens.

American Public Health Association to Hold Special War Meeting

War and its relation to public health will be the chief topic at the meeting of the American Pubic Health Association, Washington, D. C., October 17 to 20. Papers are to be presented by President W. A. Evans, Chicago; Surgeons-General Gorgas and Braistead; Colonel Goodwin of the British Army, and others. Special symposiums will be devoted to the control of venereal diseases in the Army and Navy, and to laboratory service in war time.

Making of Comfort Kits

The American Red Cross has issued circulars, which can be obtained on application at any Red Cross chapter, relative to the making of comfort kits and bags for the men of our Army and Navy. The circular embodies the suggestions of the War Department, of General Pershing and of Major Grayson M. P. Murphy, as to what the men wish. Three types of kits are suggested: a simple bag with drawstrings and two bags with pockets, one for the trenches and one suitable for hospital use. These kits are to be made of plain khaki.

Conference of Presidents of the Examining Boards Called to Meet at Fort Benjamin Harrison

Capt. George W. Kreider, M. R. C., has called a meeting of the officers and members of the various examining boards for the Medical Reserve Corps to take place at Fort Benjamin Harrison, Monday, October 8, at 11 a. m. This conference has the endorsement of the Surgeon-General, and Dr. Kreider states that already nearly one half of the boards have responded favoring the conference at that time. Important subjects relative to the work will be brought before this conference.

Medical Patriots of Rochester, N. Y.

Major John M. Swan, M. R. C., writes that the item *in* The Journal for September 22, page 1014, relative to St. Louis' contribution to the Medical Reserve Corps, leads him to send the following facts relative to the contribution of Rochester: "Fifty-five physicians have been examined and have accepted commissions in the Medical Reserve Corps, or are on duty with the Second Ambulance Company, N. G., N. Y.; Third Regiment, N. G., N. Y., now the 112th Infantry, National Army, or the New York Naval Militia. There are about 415 physicians in Rochester, which makes the percentage of Rochester physicians in the service of the government, at the present time, or who have accepted their commissions and stand in readiness to obey any order, 13.1 per cent."

Reconstruction Hospital Plans

It has been decided by the Army Medical Department to erect in Boston, New York, Philadelphia, Baltimore, Washington, Buffalo, Cincinnati, Chicago, St. Paul, San Francisco, Los Angeles, Denver, Kansas City, St. Louis, Memphis, Tenn.; Richmond, Va.; Atlanta and New Orleans, reconstruction hospitals wherein will begin a rehabilitation for private life, of soldiers who return wounded from the war front. Sites have already been chosen and it is probable that Boston, New York, Washington and Chicago will be the first cities to establish these hospitals. Each hospital will accommodate 500 patients with provision for doubling the capacity if necessary. In these institutions industrial training will be taken up and additional educational facilities will be furnished to those fitted for them. Workshops and employment bureaus will also be established for the benefit of these disabled soldiers.

Sanitary Supervision of Army Clothing Production

The production of army clothing on a tremendous scale has permitted abuses to creep in in the way of the production of such clothing in unsanitary surroundings and conditions, as the business has been farmed out by contractors and subcontractors in sweat shops and in homes. Objectionable conditions were found by the New York Child Labor Committee in instances in which the work had been given out to be done in homes, in which dangerous sanitary conditions existed and small children were found working in violation of the law. To meet the situation Secretary of War Baker appointed a board of control of labor standards, consisting of Louis E. Kirstein of Boston, Mrs. Florence Kelley, secretary of the National Consumers League, and Capt. Walter E. Kreusi of Quartermaster's Department, U. S. R. They are charged with taking such steps that the Quartermaster-General will be enabled to enforce the maintenance of sound industrial and sanitary conditions in the manufacture of army clothing, to inspect factories, to see that proper standards are established in government work, to pass on the industrial standards maintained by bidders on army clothing and to act so that just conditions prevail.

Physical Disqualification for Military Service in Italy

The Italian war department has recently issued a new official set of regulations as to the physical disqualifications for army service. The list as published recently in our Naples and Milan exchanges contains eighty-six clauses, besides a separate list of infirmities which exempt the recruit from active war service but permit him to serve on light duty, the sedentary service as it is called. One clause of the regulations provides that a register of these relatively disqualified men is to be kept at all the mobilization centers, and these men are to be called on for the sedentary service. No one is to be placed permanently on the sedentary force except those excluded by the specified infirmities from the active fatiguing war service. There has been considerable talk in Italy of late because hitherto hernia has exempted men from military service. One member of parliament, in discussing the matter recently, urged compulsory operations on men with hernia, saying that a simple operation of this kind would give the country 100,000 new and valid recruits. The new regulations alter this, as hernia now does not exclude absolutely from military service unless the hernia cannot be reduced and kept under control with suitable apparatus. It comes in the list of the infirmities permanently placing the man in the sendentary service, except what are called "button hernias." By these new arrangements, hernia no longer exempts from service but holds the man back in the sedentary service. It is optional for him, however, of course, . . . although, naturally, this is not mentioned in the *Elenco* . . . it is optional for him to have his hernia corrected by an operation which would advance him into the active ranks. Among the seventeen other infirmities which class the man permanently as fit only for the sedentary service, are facial paralysis, large and knobby hydrocele, varicocele or systocele, one leg from 3 to 5 cm. shorter than its mate, habitual dislocation of a joint, and permanent dislocation of one thumb or big toe or loss of one big toe. The *Elenco* specifies further in regard to hernia and some of the other infirmities that they are not to be classified until after the man has been under observation in a military hospital.

Orders to Officers of the Medical Corps

Lieut.-Col. G. F. Juenemann, M. C., to Gettysburg, Pa., American reorganization camp, for duty.

Lieut.-Col. E. H. Hartnett, M. C., will report in person to C. O., Western Dept., for duty.

Major J. S. Lambie, Jr., M. C., to Philadelphia, Pa., for duty as C. O. of Base Hospital No. 38, Jefferson Hospital, Philadelphia.

Major P. Waterman, M. C., to 26th Division as director of ambulance companies, with station in Boston.

The retirement of Col. G. E. Bushnell, M. C., from active service on Sept. 10, 1917, is announced.

Officers of M. C. to duty as follows: Lieut.-Col. J. W. Hanner to Camp Devens, Ayer, Mass., *76th Division*, as chief surgeon; Lieut.-Col. S. J. Morris to Walter Reed General Hospital; Major John A. Burket to Camp Sherman, Ohio, 83d Division; Major L. P. Williamson from Ayer, Mass., to Washington in connection with the division of gas defense; Major D. W. McEnery to Camp Dix, N. J., 78th Division, as division sanitary inspector; 1st Lieut. R. B. Hill from 2d Regiment of Engineers, American University, to 20th Engineers.

Lieut.-cols. of M. C. to duty as follows: W. H. Moncrief to Washington; G. McD. Van Poole to Fort B. Harrison; M. A. W. Shockley and H. F. Pipes to Fort B. Harrison.

Majors of M. C. to the place specified for duty: T. H. Johnson, Philadelphia, Pa., No. 20, University of Pa. Hospital; A. von Schrader, Albany, N. Y., No. 33, Albany Hospital and Medical College.

Major E. G. Bingham, M. C., to duty as C. O. of base hospital and as commandant of medical officers' training camp at Fort Des Moines.

Orders to Officers of the Medical Reserve Corps

ALABAMA

To Camp Beauregard, Alexandria, La., for duty, Lieut. R. Jackson, Birmingham.

To Camp Sheridan, Montgomery, Ala., in the ophthalmic division, section surgery of the head, Capt. C. A. Tipgen, Montgomery; as chief of medical service, Lieut. J. S. McLester, Birmingham.

To Fort Oglethorpe for a course of instruction, Lieuts. Andrew L. Glaze, Jr., Athens; Lucius L. Terry, Solon W. Wright, Bessemer; Rufus Jackson, M. Rogers, Birmingham; Beaman S. Cooley, Boaz; W. Theo. Langley, Camp Hill; William S. Sewell, Center; Moses E. Sherer, Childersburg; Joseph T. Banks, Dadeville; Conrad Wall, Forest Home; Thomas Y. Greet, Gadsden; Horace Van de Voort, Gastonburg; Austin F. J. Boyd, Hamburg; Francis G. Hendrick, Huntsboro; Charles W. Brasfield, Linden; Howard P. Rankin, Midway; Frederick W. Wilkerson, Montgomery; Otis W. Little, James D. Perdue, Mt. Vernon; Edward C. Hagler, Northport; John F. Jenkins, Opeliker; James P. Vansant, Piedmont; Zadoc L. Weatherford, Red Bay; Julius F. Peavy, Jr., Robertsdale; Richard B. McCann, Seale; Edmond R. Lett, Tallassee; William C. Hatchett, Toney; James W. Beard, Lucian M. Tompkins, Troy; Maxwell Moody, James H. Somerville, Jr., Tuscaloosa; William M. Pierce, Tuscumbia; Bryant B. Edwards, Union Springs, and Walter E. Allen, Ward.

To Walter Reed Hospital, Washington, for treatment, Lieut. H. L. McWhorter, Collinsville.

ARIZONA

To Camp Logan, Texas, for duty in division of ophthalmology, section of surgery of the head, Capt. A. R. Warner, Komatke.

ARKANSAS

To Camp Pike, Ark., for duty, Lieut. F. L. Castleberry, Little Rock.

CALIFORNIA

To Camp Dodge, Iowa, for duty in the division of ophthalmology, section of surgery, Lieut. W. J. Hosford, Santa Cruz.

To Camp Doniphan, Ft. Sill, Okla., for duty, Lieut. A. E. Edgerton, Stockton.

To Camp Funston, Ft. Riley, Kan., from Gas School, Ft. Sill, Okla., and report in person to the commanding general for duty as instructor in gas defense, Capt. Rutherford B. Irones, San Diego.

To Camp Kearny, Linda Vista, Calif., for duty as chief of division of otolaryngology, section of surgery of the head, Capt. R. S. Anthony, Los Gatos; for duty with 40th Division National Guard, Lieuts. G. Hoskins, Ferndale; W. D. Rolph, Riverside; C. L. Morris, Santa Barbara; and G. H. Sciaroni, Sutter Creek.

To Camp Logan, Houston, Tex., from Gas School, Ft. Sill, Okla., and report in person to the commanding general for duty as instructor in gas defense, Capt. Fred. F. Sprague, Los Banos.

To Camp Mills, Garden City, N. Y., 42d Division, for duty, Lieut. A. H. Martin, Courtland.

To Camp Travis, Tex., for duty, Major H. C. Moffitt, San Francisco.

To Fort McDowell, Calif., for duty, Lieuts. W. J. Haber, and J. F. Chapman, San Francisco.

To Houston, Tex., Av. School, for duty, Capt. L. F. Luckie, Los Angeles.

To report in person to commanding general Western Department, for duty, Capt. E. L. Wemple, San Francisco; Lieuts. G. P. Tolman, Sacramento; and L. G. Seidenfeld, San Francisco.

COLORADO

To Camp Doniphan, Okla., for duty in division of ophthalmology, section of surgery of the head, Capt. A. C. Magruder, Colorado Springs; from Gas School, Ft. Sill, Okla., and report to commanding general for duty as instructor in gas defense, Lieut. William M. Bane, Denver.

To Fort Benjamin Harrison for a course of instruction, Lieut. Orion A. Grantham, Johnstown.

To Fort Oglethorpe, for a course of instruction, Lieut. Harry B. Sobernheimer, Meeker.

To Linda Vista, Calif., for duty in division of ophthalmology, section of surgery of the head, Lieut. F. N. Stiles, Grand Junction.

To San Francisco, Calif., for duty, Capt. W. A. Jones, Denver.

CONNECTICUT

To Camp Bartlett, Westfield, Mass., for duty, Lieut. W. F. Collins, New Haven.

To Camp Mills, Garden City, N. Y., 42d Division, for duty, Lieut. F. C. Young, Colchester.

To Fort Benjamin Harrison, for duty, Capt. L. I. Mason, Willimantic.

DISTRICT OF COLUMBIA

Camp Lewis, American Lake, Wash., *for duty as chief of the* service, Lieut. C. S. White, Washington.

Camp Sheridan, Montgomery, Ala., for duty, Lieut. J. L. Gariss, ashington.

To Fort Oglethorpe for a course of instruction, Lieuts. Charles Bell, and John H. Digges, Washington.

FLORIDA

To Camp McClellan, Anniston, Ala., from Gas School, Ft. Sill, Okla., and report in person to the commanding *general for duty as* instructor in gas defense, Lieut. George G. Tillman, Barton.

To Camp Sevier, S. C., for duty in division of ophthalmology, section of surgery of the head, Capt. J. Halton, Sarasota.

To Camp Taylor, Louisville, Ky., *from Gas School*, Ft. Sill, Okla., and report in person to the commanding general for duty as instructor in gas defense, Lieut. Lester J. Efird, Tampa.

To Fort Oglethorpe, for a course of instruction, Capt. Joseph N. Fogarty, Key West; Lieuts. Joseph H. Chirles, Clearmont; Henry F. Parnell, Ft. Myers; William E. Whitlock, Ft. White; Charles L. Kennon, Elijah T. Sellers, Jacksonville; Hugh St. C. Geiger, Kissimmee; Dwight D. Rivers, Lake City; Archie C. Watson, Live Oak; Adam C. Walkup, McIntosh; James R. McEachern, Monticello; Harold M. Beardall, Orlando; John C. Holley, Pace; MacMiller Harrison, Palmetto; Baldwin S. Stutts, Pt. St. Joe; Daniel B. Williams, South Jacksonville; William J. Lancaster, Tampa; from Gas School, Ft. Sill, Okla., and report to the commandant, Medical Officers' Training Camp, for duty as instructor in gas defense, Richard Leffers, Lakeland.

To Syracuse, N. Y., for regimental duty, Capt. H. F. Watt, Ocala; Lieuts. W. H. Pickett, Gainesville; A. L. Izlar, Ocala; and J. W. McClane, St. Petersburg.

GEORGIA

To Camp Gordon, Ga., for duty in the division of ophthalmology, section of surgery, Capt. R. R. Daly, Atlanta.

To Fort Oglethorpe, for a course of instruction, Lieuts. Cecil Stockard, James R. Smith, Atlanta; Henry D. Coffee, Auburn; David M. Silver, Augusta; Joseph E. Mercer, Baxley; Philip G. Fitzgerald, Blakely; A. Nathan Dykes, Columbus; Whitfield W. Crook, Cuthbert; Leslie L. Blair, Marietta; Carl H. Verner, Martin; Homer G. Lightner, Montezuma; Hugh W. Wade, Quitman; Burton P. Bradley, Joseph H. Mull, Rome; George L. Fuguary, Savannah; John C. Call, Sylvania, Robert C. Walker, Waycross; and John W. Bradley, Woodstock.

HAWAII

To Fort Kamehameha, H. T., from Ft. Ruger, H. T., for duty as post surgeon and surgeon of the Coast Defense of Oahu, Major E. W. Bayley, Ft. Ruger.

To Fort Oglethorpe, for a course of instruction, Major Harry R. McKellar, Ft. Shafter.

ILLINOIS

To *Camp Custer*, Mich., from Fort Benjamin Harrison, for duty as chief of medical service, Major E. E. Irons, Chicago.

To Camp Devens, Mass., for duty in the division of ophthalmology, section of surgery, Lieut. W. G. McDeed, Monticello.

To Camp Grant, Rockford, Ill., from Gas School, Fort Sill, Okla., *and report to the commanding general for* duty as instructor in gas defense, Capt. John S. Sweeney; for duty in the division of ophthalmology, section of surgery, Lieuts. H. S. Cradle; for duty, F. M. Phifer, Chicago.

Logan, Texas, for duty in division of ophthalmology, sec-
of the head, Lieut. J. F. Strauss, Chicago.
Ark., as chief of medical service, Major A. A. Small,

Miss., for duty in division of ophthalmology, sec-
the head, Lieut. C. M. Wilmot, Spear.
Chillicothe, Ohio, Base Hospital, as surgical chief,
Chicago; as C. O. of Red Cross Ambulance Co.
; with Red Cross Ambulance Co. No. 9, Lieuts
and J. E. McNeel, Chicago.
, Ky., Eighty-Fourth Division, for duty, Capt. F. S.
; for duty as chief of medical service, Lieut. W. W.

Harrison, for a course of instruction, Capt.
Edwardsville; Lieuts. Ira J. Magee and Thaddeus
For duty with Base Hospital No. 36, Lieut.

Iowa, for duty, Lieut. L. C. Gatewood, Chicago.
H. T., from Schofield Barracks, for duty,
Fairbury.
, from Fort Riley, and report in person to the
Shelby, for duty, Lieut. Alexander W.

To Fort Sheridan, Ill., for duty, Lieut. K. J. Henrichsen, Chicago.

To Jefferson Barracks, Mo., for duty, Lieut. S. Horwitz, Peoria.

To Neurological School, University of Pennsylvania, for a four weeks' course of *intensive training in brain surgery*, Lieut. George H. Schroeder, Chicago.

To report to commanding officer, Ambulance Co. No. 9, for duty, Lieut. J. P. Cleary, Chicago.

To Syracuse, N. Y., for regimental duty, Lieut. C. W. Shaffer, Chicago.

To Waco, Texas, Aviation School, for duty, Lieut. E. C. Gaffney, Lincoln.

INDIANA

To Camp Custer, Battle Creek, Mich., for duty, Lieut. T. I. Padgett, Jasonville.

To Camp Dix, N. J., *for duty in the division* of ophthalmology, section of surgery, Lieut. G. G. Van Mater, Peru.

To Camp Funston, Fort Riley, Kan., Lieut. R. C. Shanklin, South Bend.

To Camp Green, Charlotte, N. C., from Gas School, Fort Sill, Okla., and report in person to the commanding general for duty as instructor in gas defense, Capt. Leonard A. Ensminger, Indianapolis.

To Camp Shelby, Hattiesburg, Miss., from Gas School, Fort Sill, Okla., and report in person to the commanding general for duty as instructor in gas defense, Lieut. James A. Work, Elkhart.

To Camp Sheridan, Montgomery, Ala., from Gas School, *Fort Sill*, Okla., and report *in person to the commanding* general for duty as instructor in gas defense, Lieut. Oliver O. Alexander, Terre Haute.

To Fort Benjamin Harrison, for a course of instruction, Lieut. Joseph A. Graham, Hammond.

To Fort Oglethorpe, for a course of instruction, Lieut. Edwin W. Rodengeiser, Indianapolis.

IOWA

To Camp Dodge, Iowa, for duty in the division of ophthalmology, section of surgery, Capt. L. L. Henninger, Council Bluffs.

To Camp Grant, Ill., for duty *in the division of ophthalmology*, section of surgery, Lieut. E. J. Lambert, Ottumwa.

To Fort Oglethorpe, Ga., Lieut. J. A. White, Olin.

To Fort Riley, for duty, Capts. A. Negus, Keswick, and W. S. Norton, Muscatine.

To Washington, for duty, Capt. G. McConnell, Waterloo.

KANSAS

To Ambulance Co. No. 9, from post hospital, Schofield Barracks, Lieut. L. A. Clary, Hutchinson.

To Camp Cody, Deming, N. M., *for duty and report in person to* commanding general for purpose of making examinations in his specialty of recruits for the National Army, *Major John E. Hewitt*, Wakefield.

To Fort Houston, Texas, for duty, Lieut. P. B. Matz, Leavenworth.

To Fort Leavenworth, for duty, Capt. J. F. McGill, Fort Scott.

To Fort Oglethorpe, for a course of instruction, Lieuts. Richard C. Henderson, Pittsburg, and William J. Stewart, Summerfield.

KENTUCKY

To American University, Wash., for duty, Lieut. F. K. Foley, Central City.

To Camp Beauregard, La., for duty in division of ophthalmology, section of surgery of the head, Capt. R. Lockhart, Owensboro.

To Camp Shelby, Miss., for duty in division of ophthalmology, section of surgery of the head, Capt. O. Le R. Smith, Lexington.

To Fort Benjamin Harrison, for a course of instruction, Lieuts. Augustus B. Riley, Hartford, and Frank B. Dewitt, Rockport.

LOUISIANA

To Camp Beauregard, Alexandria, La., from Gas School, Fort Sill, Okla., and report in person to the commanding general for duty as instructor in gas defense, Lieut. Francis S. Furman, Shreveport.

To Fort Oglethorpe, for a course of instruction, Lieuts. William T. McNeese, Angie; Spears O. Turner, De Ridder; Harper L. Crow, Elmgrove; George B. LeSuer, Gonzales; Edwin O. Simonton, Jonesboro; Wiley R. Buffington and Irenaeus N. Tucker, New Orleans; Christopher L. Mengis, Norwood, and Clifford P. Rutledge, Shreveport.

To Syracuse, N. Y., for regimental duty, Lieut. H. N. Stilphen, New Orleans.

MAINE

To Camp Mills, Garden City, N. Y., for duty in division of ophthalmology, *section of* surgery of the head, Capt. W. E. Kershner, Bath; Forty-Second Division for duty, Lieut. H. S. Babcock, Castine.

MARYLAND

To American University, Washington, Second Regiment of *Engineers*, Lieut. F. H. Herman, Baltimore.

To Camp Devens, Ayer, Mass., Lieut. G. B. Wislocki, Baltimore.

To Camp Meade, Annapolis Junction, Md., for duty, Lieuts. J. H. Truitt, Bowie; F. O. Miller, Elliott City, and W. H. Kable, Woodsboro.

To Camp MacArthur, Waco, Texas, from New York Neurological Institute, New York, and report in person to commanding general and to commanding officer base hospital, for the purpose of *making examination* in his specialty, Lieut. George H. Preston, *Baltimore*.

To Camp Sheridan, Montgomery, Ala., from *Boston* Psychopathic Hospital, Boston, and report in person to the commanding general, and to the commanding officer base hospital, for the *purpose* of making examination in his specialty, Lieut. Milford Levy, Baltimore.

To Fort Benjamin Harrison, for a course of *instruction*, Capt. Compton Wilson, Friendship.

To Fort Oglethorpe, for a course of instruction, *Capt.* Henry R. Carter, Jr., Lieuts. James S. Akehurst, *Robert G. Fuller*, William R.

Geraghty, George H. Reinhardt, Harry C. Schmeisser, David Silberman, Daniel C. W. Smith, Horace B. Titlow, Baltimore; Alexander McC. Stevens, Easton; Oscar H. McNemar, Edenton; Richard E. Yellott, Fallston; Charles L. Magruder, New Market; Samuel J. Price, Queenstown, and Joseph W. Long, Walkersville.

MASSACHUSETTS

To Atlantic City, N. J., from Washington, D. C., for the purpose of attending a conference on the question of reconstruction hospitals, and on completion of this duty to return to his proper station, Major Elliott G. Brackett, Boston.

To Ayer, Mass., for duty as chief of division of otolaryngology, section of surgery of the head, Capt. W. F. Knowles, Boston.

To Camp Devens, Ayer, Mass., for duty, Major W. B. Lancaster, Brookline; Lieuts. V. S. Merritt, Springfield; A. A. K. Yoosuf, Worcester; from Gas School, Fort Sill, Okla., and report in person to the commanding general for duty as instructor in gas defense, Lieut. Daniel F. Mahoney, Boston.

To Camp Dix, Wrightstown, N. J., from Gas School, Fort Sill, Okla., and report in person to the commanding general for duty as instructor in gas defense, Capt. Frederick R. Ilsley, Medford.

To Camp McClellan, Ala., for duty as chief of the medical service, Capt. W. H. Robey, Jr., Boston.

To Camp Jackson, Columbia, S. C., from Gas School, Fort Sill, Okla., and report in person to the commanding general for duty as instructor in gas defense, Lieut. John M. Birnie, Springfield.

To Camp Sherman, Ohio, for duty in the division of ophthalmology, section of surgery, Capt. R. H. Powell, Fairmont.

To Camp Wadsworth, Spartanburg, S. C., for duty in the division of ophthalmology, section of surgery of the head, Lieut. C. F. Mahood, Alderson.

Paragraph 2352, Aug. 17, 1917, War D., which recommends the revocation of so much of Par. 119, Special Orders No. 189, War D., Aug. 15, 1917, as related to Lieut. William C. Williams, Caretta, be revoked.

WISCONSIN

To Camp Kearny, Calif., as chief of surgical service, Major J. R. McDill, Milwaukee.

To Camp MacArthur, Texas, for duty in division of ophthalmology, section of surgery of the head, Lieut. L. J. Bennett, Fort Atkinson.

To Camp Pike, Ark., for duty in the division of ophthalmology, section of surgery, Lieut. W. W. Pretts, Platteville.

To Fort Benjamin Harrison, for a course of instruction, Lieut. George E. Towel, Mosinee.

To Fort Snelling, Minn., for duty, Capt. R. M. Nichols, Sheboygan Falls.

To Hoboken, N. J., for duty, Capt. F. J. Peirce, Cheyenne.

Medical News

(Physicians will confer a favor by sending for this department items of news of more or less general interest; such as relate to society activities, new hospitals, education, public health, etc.)

CONNECTICUT

Personal.—Dr. George Blumer, dean of the Yale Medical chool, has been appointed a member of the board of educaion of New Haven.

ILLINOIS

Medical Schools Merged.—Word has been received that Loyola University has taken over the Chicago College of Medicine and Surgery and merged it with its own medical department.

Chicago

Billings and Post on Way Back.—As noted elsewhere in this issue, the Red Cross Commission to Russia is now on its return to this country. Drs. Frank Billings and Wilber E. Post of Chicago are members of this commission.

Women for War Service.—Nearly 100 women physicians, at a meeting held in the rooms of the State Council of Defense, September 22, volunteered to assist in the registration of Chicago women for war service. The registration week will begin November 5.

Poliomyelitis.—There have been 153 cases of infantile paralysis in the city for the first twenty-one days of September, with two deaths. All cases are hospitalized within twenty-four hours after being reported. To defray the cost of hospitalization of cases and to fight the disease generally, the health commissioner has asked an appropriation of $118,000.

Personal.—The following is the medical staff of the newly organized Eleventh Infantry: Major B. McPherson Linnell and Lieuts. Walter H. Meents, Claude H. Searle, Wilmette, and Louis B. Cardwell.——Dr. John Ridlon has been commissioned major, M. R. C., U. S. Army, and assigned to special work in orthopedic surgery.——Dr. J. Clarence Webster, who was operated on some months ago, and who has been convalescing in Canada, has returned to Chicago.

Infantile Paralysis.—The total number of cases of infantile paralysis the first eight months of 1917 was eighty-two, as compared with 155 for the same period of 1916. In 1916 the disease began to abate by the end of August. This year, however, the number of cases increased, and for the first fourteen days of September, eighty-seven new cases were reported, as compared with twenty-five for the same period in 1916. In the eighty-seven cases, twenty-three patients died, a percentage of 26.4, as compared with 16.1 for the total number of cases in 1916. A conference of physicians called by the health commissioner to discuss ways and means of preventing a spread of the epidemic reported that there is an active focus of the disease in the lower northwest side of Chicago, and that proper intensive measures should be adopted, with ample funds for stamping out the disease. It was said that no cases of infection due to contact with other cases have been observed. Two cases, however, occurred in the same family within three days. Careful investigation failed to show any relation of the disease to the milk supply. Early in 1916 the health commissioner asked the city authorities for $500,000 as a contingent fund to fight the disease. The sum was not granted on account of lack of funds. The health commissioner has now renewed his demand for sufficient funds to combat the disease.

INDIANA

Sanatorium Transformed to Hospital.—A forty-bed sanatorium, refurnished and equipped, was turned over recently to the Methodist state hospital board at Princeton. There was a clear deed and a maintenance fund of $7,000.

Hospital Opened.—The new hospital at Marion was opened for inspection, August 24. The transfer of patients began, August 27, and was completed in two days. The hospital has been built and furnished by public subscription at a cost of $70,000, and will accomodate seventy-five patients.

District Physicians Hold Meeting.—South Bend has been chosen as the place for the 1918 meeting of the Thirteenth District Medical Association. The following officers were elected at the recent meeting at Rochester: Dr. John C. Fleming, Warsaw, president; Dr. Samuel C. Loring, Plymouth, vice president; Dr. C. Norman Howard, Warsaw, secretary-treasurer, and Dr. Hugh M. Miller, South Bend, counselor.

Typhoid Fever.—September 21, ninety-eight cases of typhoid fever were reported in South Bend. Under the advice of Surg. Julius O. Cobb, U. S. P. H. S., the following measures have been recommended: chlorination of the water supply; boiling of all well water; the use of pasteurized or boiled milk, and antityphoid inoculation.

State Health Board to Exhibit.—The state board of health, in connection with the Indiana Anti-Tuberculosis Society and the Marion Society for the Prevention of Tuberculosis, is preparing a very extensive health exhibit at the state fair which is to be housed in three tents each 30 by 60 feet. Motion pictures will be shown, and the state board of health will be represented in the departments of public hygiene, pure food, weights and measures, water analysis, and laboratory.

Personal.—Dr. Augustus L. Marshall has been elected secretary of the Indianapolis Medical Society, succeeding Dr. Leslie H. Maxwell, who is on duty with Base Hospital No. 32.——Dr. Lewis P. Drayer has been appointed secretary of the health board of Fort Wayne, succeeding Dr. John H. Gilpin, who is on duty at Fort Benjamin Harrison.——Dr. Edmond D. Clark, Indianapolis, director of Base Hospital No. 32, gave a dinner to the members of the staff at the university club, August 29.——Dr. Sarah C. Jackson, Jeffersonville, one of the founders and trustees of the Odd Fellows' Home at Greenburg, has retired from practice, and has gone to the home to live. A dinner was given in her honor by the physicians and other friends at Jeffersonville.

MARYLAND

Personal.—Dr. Frank Martin and Dr. William H. Smith, who are on the staff of the University of Maryland Base Hospital Unit, have left for Philadelphia, where they expect to review the study of brain surgery, preparatory to going to France with the unit.——Dr. John S. Fulton, secretary of the Maryland State Board of Health, who is a captain in the Medical Reserve Corps, has been named on a board appointed by Major-Gen. William C. Gorgas to prepare a medical and surgical history of American participation in the European War.——Dr. Wright S. Sudler has been appointed one of the health officers of Baltimore County, vice Dr. William E. McClanahan, Highlandtown, who has received a commission as captain in the Medical Reserve Corps.

MASSACHUSETTS

Personal.—Col. Frank P. Williams, Boston, of the Massachusetts National Guard, has been assigned to the twenty-sixth division as divisional sanitary inspector.——Dr. Gualtiero De Amezaga, Roxbury, Boston, was seriously injured in an automobile accident at Winchester, August 29.

Correction of Speech Disorders.—Dr. Walter B. Swift, Boston, has been appointed medical supervisor of speech classes in the public schools of Fall River. He has instructed teachers who will install his methods and systems of treating speech disorders in the school and form classes for phonetics, stuttering and mental defects.

MICHIGAN

Hospital Under Quarantine.—The Homeopathic Hospital at Ann Arbor was placed under quarantine, September 7, on account of the occurrence of four cases of virulent diphtheria. Two diphtheria patients died.

Personal.—Dr. Clara M. Davis, Lansing, has returned after six months in the Orient.——Dr. Allison H. Edwards has taken charge of the Grand Rapids Tuberculosis Sanatorium pending the appointment of a superintendent to succeed Miss Emma Frieby, resigned.

NEW YORK

Personal.—Dr. Frank L. Christian, Elmira, has been appointed superintendent of the Elmira Reformatory and the Eastern New York Reformatory, Napanoch.

Gibson Acquitted.—Dr. William B. Gibson, health officer of Huntington and coroner of Suffolk County, was acquitted, September 7, of the charge of having performed an illegal operation on a woman of Huntington.

Appropriation for Farm Hospital Granted.—The request of Dr. Walter S. Goodale for an additional $100,000 for the equipment of the West Farm Hospital was granted by the Buffalo City Council, September 14.

Typhoid Fever.—September 7, there were reported in the epidemic of typhoid fever at West New Brighton, Staten Island, fifty cases of typhoid fever, and 1,000 citizens had been inoculated with antityphoid serum. The inoculations will be continued.

New York City

Budget for 1918.—Health Commissioner Haven Emerson estimates the expense of his department for 1918 as $4,101,046, or $727,457 more than the appropriation for 1917. Of this increase, $368,389 is for personal service, and $314,595 for new positions.

Public Health Service Changes.—Senior Surg. George W. Stoner, U. S. P. H. S., who for the past four years has had charge of the Marine Hospital at Stapleton, L. I., has been retired from active duty, having served forty years. Dr. Claude H. Lavinder is now in charge at Stapleton.

Medical Examiners Replace Coroners.—At a meeting of the Board of Estimate and Apportionment, September 13, the four coroners in Manhattan, two in Brooklyn, two in the Bronx, two in Queens, and two in Richmond borough will retire at the end of the year, and will be replaced by a chief medical officer in each borough. This will decrease the expenses of the office at least $40,000 a year.

New Broad Street Hospital Completed.—The new Broad Street Hospital has been opened for the reception of patients without any formal ceremony, the dedication having been deferred until some time next month. A dispensary is conducted in connection with the hospital, and two motor ambulances have been placed at the disposal of the public. This hospital was erected at a cost of $270,000, and is one of the best equipped hospitals of its size in the city. This will meet the needs of that portion of the city lying below Canal Street and between the North and East rivers.

Indictments in Diploma Case.—The Grand Jury has filed additional indictments against "Dr." Nicholas Clements and his wife, Rose Clements, and Joseph Budd, all of whom were recently arraigned, and who are alleged to have conducted a diploma factory where it was possible to purchase regent's certificates, college diplomas, and even licenses to practice medicine. Further investigations have resulted in the discovery of several additional persons who are alleged to have been practicing medicine under diplomas or licenses obtained from this source. One of these diplomas purported to be from a medical institution of high standing in Vienna, Austria.

Medical Colleges Open to Women.—Announcement has been made that the College of Physicians and Surgeons of Columbia University will be open to women during the coming month. This step has been hastened by conditions arising from the war, and has been made possible by a gift of $50,000 from George W. Breckenridge, San Antonio, Texas.——Women are also for the first time to be admitted to the medical department of New York University.——Preliminary work in biology, chemistry and physics will be offered at the New York Homeopathic Medical College and Flower Hospital.

NORTH CAROLINA

Public Health Laboratory.—Wilmington and New Hanover county have a well equipped laboratory for the free diagnosis of infectious disease, with a competent bacteriologist and chemist in charge. The bulletin of the health authorities of these municipalities complains that the facilities of the laboratory are not used as freely as they should be by the physicians of the district. It is said that cases of typhoid fever are still being diagnosed by the symptoms rather than by the laboratory findings, and fever cases that subside in a few days after the administration of quinin are called malaria, while those in which the treatment fails may be found to be typhoid fever. It is said that many cases of paratyphoid fever proceed to recovery without differential diagnosis. Criticism of the board and the laboratory, which, it is claimed, is not justified, is sometimes heard. A plea is made for a better acquaintance with the laboratory and its purposes.

OHIO

Epidemic of Typhoid Fever.—September 7, it was reported from Harrod that twenty-five persons had become ill with typhoid fever, which was supposed to have been caused by ice cream cones eaten at a family reunion. Many of the cases are said to be serious.

Dentists and Anesthetics.—In a rule made by Attorney-General McGhee, September 6, dentists may legally administer anesthetics both in the practice of dentistry and in other cases. The state medical board has contended heretofore that only physicians could legally administer anesthetics.

Personal.—Dr. Allen W. Freeman, Richmond, Va., epidemiologist in the United States Public Health Service, and formerly assistant state health commissioner of Virginia, has been elected state health commissioner of Ohio, to succeed the late Dr. George H. Matson, at a salary of $6,000 a year. He will enter on his duties, October 1, with headquarters at Columbus.

Taking Care of the Poor.—At Marion, September 7, twenty-five members of the local medical society associated themselves together as a staff to take care of such indigent patients as require hospital care who may be reported to them by the Social Service League. A division of the work will be made into the various specialties. The arrangement, it is understood, is to be continued during the war.

OKLAHOMA

Personal.—Dr. Samuel M. Hunter, Oklahoma City, has succeeded his son, Dr. George Hunter, as city physician.——It is reported that the state board of medical examiners has revoked the license granted Dr. Thomas E. Shepherd, Tulsa, who is charged with having performed a criminal operation in May last which resulted in the death of the patient. The complaint to the state board was signed by Dr. S. De Zell Hawley for the county medical society.

OREGON

Personal.—Dr. Frank M. Brooks, Portland, has been appointed a member of the state board of health, to succeed Dr. Marius D. Marcellus, who was called to the colors.——In the places of Dr. Henry E. Clay, Salem, and Dr. David N. Roberg, secretary of the board, who have also joined the Army, Drs. William H. Dale, Harrisburg, and Robert E. L. Holt, La Grande, have been serving.

PENNSYLVANIA

Typhoid Fever.—Typhoid fever is reported to be epidemic at East Petersburg, where there are at present fourteen cases.

Personal.—Dr. Charles B. Dreher, Tamaqua, was given a banquet, September 14, to commemorate the completion of half a century in the practice of medicine.——Dr. W. Roland Davies, West Scranton, has been elected president of the Craftmen's Club.——Dr. Lowell M. Gates has been elected president of the American Bank of Commerce, Scranton.

Philadelphia

Addresses County Medical Society.—Dr. Alfred Gordon, Philadelphia, delivered an illustrated lecture before the York County Medical Society at its annual meeting, September 6, on the differential diagnosis and treatment of the more common neurologic conditions met with in general practice.

Personal.—Dr. Earle B. Stokes has been commissioned first lieutenant, N. G., Pa., and assigned to duty with the First Cavalry.——Lieut. Charles S. Pancoast, having been found physically disqualified for military service, has been mustered out of the service of the United States under date of August 3, and was honorably discharged from the Pennsylvania National Guard, August 4.

Medical Institutions.—Jefferson Medical College held its ninety-third annual opening exercises, September 24. The introductory address on "How to Study" was delivered by Dr. Chevalier Jackson, professor of laryngology.——The Woman's Medical College opened its school year, September 19, with an address by Dr. Martha Tracy, dean of the college. There has been an increase of 50 per cent. over last year in the entrance enrolment.

Medico-Chirurgical Notes.—The board of review appointed to assess damages for property taken by the city for the parkway has awarded $714,500 to the University of Pennsylvania for the old Medico-Chirurgical College and Hospital property taken by the university in the merger proceedings. With the exception of the hospital, which will be retained for use in case of war emergency, all the buildings of the group will be torn down.

SOUTH DAKOTA

Personal.—Dr. Oscar W. Phelps, Lemmon, has been bequeathed $50,000 by the will of a former patient in Hope, Ill.

TEXAS

New Health Board.—A new board of health has been appointed from San Antonio, consisting of Charles S. Venable, John H. Burleson, Dabney Berrey and Thomas T. Jackson. The board reappointed Dr. William A. King as city health officer.

State Quarantine Station to Be Built.—It is announced that the work on the State Quarantine Station at Sabine Pass, construction of which was authorized some time ago, will be begun in the near future. An appropriation of $85,000 was made for this purpose.

Psychiatric Appointments.—Dr. John Preston, superintendent of the State Insane Hospital, Austin, has been appointed by the Medico-Psychological Society to organize neuropsychiatric hospital units to be attached to the base hospitals and other military sanitary units. Dr. Preston has appointed the following committee to carry out these plans: Drs. Marvin L. Graves, Galveston; John S. Turner, Dallas; George F. Powell, Terrell; Thomas B. Bass, Abilene; James R. Nichols, Austin, and John W. Bradfield, Austin.

VIRGINIA

Infantile Paralysis.—August 30, the city board of health of Harrisonburg appropriated $1,000 for fighting infantile paralysis, which had occurred in epidemic form in the city. Cases had occurred at Winchester and other places in Rockingham County. About September 16, the disease had been brought under control, and quarantine was lifted throughout the county. Since the disease was first reported in April there have been sixty-two cases, twelve of which resulted fatally.

CANADA

University News.—At a recent meeting of the board of governors of Manitoba University, a resolution was proposed that no unmarried man of 20 years or over be permitted to attend lectures or take examinations unless he furnishes satisfactory reasons why he has not enlisted. A proposal for the compulsory military training of male students was approved.

Infantile Paralysis in Ontario.—Forty-three cases of infantile paralysis, three of which have proved fatal, have been reported in the past few weeks in Ontario. The following figures show the sections of the province affected: Toronto, 7; Ottawa, 8; Edwardsburg, 7; Cardinal, 6; Cornwall, 9, and Ferguson, 2. These figures show the extreme eastern part of the province mostly affected.

Venereal Disease Committee.—The committee on the prevention of venereal diseases which has been active for some time in Toronto is to be made a permanent organization, and will be known as the Advisory Committee on Venereal Disease for Military District Number 2. Major John G. Fitzgerald has been elected president; W. S. Gundy, treasurer, and Capt. W. Gordon Bates, secretary.

Personal.—Dr. Percy W. M. Curry, Montreal, has left for Valcartier, Que., to join the C. A. M. C., and expects to go overseas shortly.——Dr. Albert E. MacCaulay, superintendent of the General Hospital, St. John, N. B., has resigned.——Dr. Alfred B. Atherton, formerly of Fredericton, N. B., has retired from practice, and has taken up residence at San Diego, Calif.——Capt. A. H. Hall, who was wounded in France, has resumed practice in Quebec City.——Dr. Robert G. Ferguson, Winnipeg, has been appointed medical superintendent of the Qu'Appelle Sanatorium, pending the return of Dr. Fred J. Hart, who is on active service.——Among the recently wounded are: Capts. J. Harold Jones, Vancouver, B. C.; Robert Mackenzie, Vancounver, B. C.; Richard W. Kenney, Winnipeg, and James E. Bloomer, Moose Jaw, Sask., all of the C. A. M. C.——Dr. William L. Denny, Western University, London, Ont., 1917, has obtained a commission in the Royal Navy as medical officer.——Dr. Duncan A. McKillop, St. Thomas, Ont., Western University, London, has been appointed surgeon with the Royal Navy.——Lieut. Donald Neil Stuart, V. C., D. S. O., R. N. R., Prince Edward Island, has been given the Victoria Cross for services in action with enemy submarines.——Capt. Alexander L. McQuarrie, medical officer of health, New Westminister, B. C., and who went overseas with the 121st Battalion as regimental medical officer, has been appointed officer commanding Canadian Sanitary Section No. 7 in England.——Major Angus W. McPherson, C. A. M. C., medical officer of health, Peterboro, Ont., has returned to Canada for two months' leave of absence.——Dr. Louis De L. Harwood, superintendent of the Notre Dame Hospital, Montreal, has left Canada to join the staff of Laval Military Hospital in France.——Capts. L. J. Siebert and Hereward D. Livingstone, Toronto, Lieut. John M. Mac Donald, Toronto, C. A. M. C., and Dr. Percival E. Faed, Grace Hospital, Toronto, have left for China.——Lieut.-Col. John R. Spier, Westmount, C. A. M. C., is in command of the Canadian Hospital, Bromley, England.——Capt. Harold A. Simpkins of the Spadina Convalescent Hospital, Toronto, has been transferred to England.——Capt. Frank S. Park, C. A. M. C., who was taken prisoner by the Germans in June, 1916, was attached to the Fourth Canadian Mounted Rifles. He asked permission to attend the allied prisoners at Minden Hospital, where there are 2,000 prisoners, and for some months has been acting as medical officer to that hospital.

GENERAL

Organization of Dental Surgeons.—The association of military Dental Surgeons of the United States has been organized, with offices in San Francisco. Dr. John D. Millikin is president of the association, which publishes a quarterly bulletin of dentomilitary news.

Correction.—Dr. F. A. Faught writes that in his discussion of Dr. Slemon's paper, The Journal, September 8, p. 780, lines 9, 10 and 11, should be corrected to read: "This corresponds with the 3:2:1 ratio; that is, the pulse presssure is ⅓ the systolic and ½ the diastolic."

Industrial Accidents Considered.—The International Association of Industrial Accident Boards and Commissions held its fourth annual meeting at the state house, Boston, August 21 to 24. Among the subjects discussed were, "Medical Competence and Hospital Efficiency," and "Compensation Insurance."

Correction.—Dr. Curtis F. Burnam writes that a typographical error appears in the report of his discussion on the papers on radium, The Journal, September 22, page 996. In the sentence: "In the cases which I am reporting I feel that the results could be duplicated by the use of 3 or 4 mg., although I have used myself as much as a gram or two with some of them," the numerals 3 or 4 should be 300 or 400.

Personal.—Rear Admiral Charles F. Stokes, U. S. Navy, retired, and until recently medical director of the board of inebriety and in charge of its country retreat at Warwick, N. Y., is reported to be seriously ill at Brian Cliff Manor, N. Y.——Dr. Ross H. Skillern, Philadelphia, has accepted a commission as major in the Medical Reserve Corps, and has been placed in charge of the nose and throat unit at Camp Sheridan, Montgomery, Ala.

Bequests and Donations.—The following bequests and donations have recently been announced:

Chicago Home for Crippled Children, $5,000, and Iroquois Memorial Hospital, $500, by the will of Mrs. Kate Adams Cooper, Chicago.

Misericordia Hospital, Philadelphia, a donation of $10,000 for the establishment of a ward to be known as the Elinor C. Donnelly room.

Lincoln Hospital and Home, New York, $81,000; New York Orthopedic Dispensary and Hospital, and New York Society for the Prevention of Cruelty to Children, each $40,615, and St. John Guild, $240,890, by the will of Mrs. Helen Juilliard, New York.

Yale Medical School, New Haven, a donation of $100,000 for the Harriman Fund for Obstetrics, by Mrs. Edward H. Harriman, and a donation of $50,000 by Charles N. Brooker, Ansonia.

Pennsylvania Hospital, the furnishings of the Tate Home; Pennsylvania Indigent Widows, and Single Women, Philadelphia, $10,000 in trust, by the will of Susan Tate.

University Museum, Philadelphia, donation of the archeological and ethnological collections of the late Dr. William White, by his widow.

Montefiore Home, New York, $1,000, and to Mount Sinai Hospital his residuary estate, by the will of Julian A. Hellman.

War Tuberculosis.—Preparations for the extensive campaign to prevent the spread of tuberculosis in the United States Army and in the conscripts rejected by the draft will be the theme for discussion at the meeting of the Southern Sectional Conference of the National Association for the Study and Prevention of Tuberculosis which is to be held in Chattanooga, Tenn., November 9 and 10. The officers of the conference are as follows: president, Dr. Lewis B. McBrayer, Sanatorium, N. C.; vice presidents, Dr. Louis A. Bize, Tampa, Fla.; Mr. W. N. Runn, Asheville, N. C.; Dr. Robert Wilson, Jr., Charleston, S. C.; Mr. C. E. J. Mooney, Memphis, Tenn.; Mr. Kendall Weisigner, Atlanta, Ga.; Dr. Gaston J. Greil, Montgomery, Ala., and Mrs. Edward McGehee, New Orleans, and secretary, James P. Kranz.

Mississippi Valley Conference on Tuberculosis.—The fifth session of the Mississippi Valley Conference on Tuberculosis will be held at Minneapolis and St. Paul, October 8-10, under the presidency of Mr. James Minnick, Chicago. The object of the conference is to bring up a closer relationship between antituberculosis agencies in the Mississippi Valley, and provide for the interchange of ideas and experiences; to strengthen and extend the work of the National Association for the Study and Prevention of Tuberculosis; to arouse the people of this valley to the need for concerted action, both public and private, against tuberculosis, and to effect closer cooperation between antituberculosis societies and other health agencies. The headquarters will be at the Radisson Hotel, Minneapolis, for October 8 and 9, and at the St. Paul Hotel, St. Paul, October 10. The states of Ohio, Michigan, Indiana, Wisconsin, Illinois, Kentucky, Minnesota, Iowa, Missouri, North Dakota, South Dakota, Nebraska and Kansas are included in the conference. On the second day the first annual meeting of the Mississippi Valley Sanitarium Association will be held, at which Dr. James W. Pettit, Ottawa, Ill., will preside. On the afternoon of October 10, the tuberculosis problems of the war will be the topic for discussion.

Poliomyelitis.—Since September 10, cases of poliomyelitis have been reported in the press from the following places: Chicago, September 21, there had been 142 cases, with 2 deaths; September 11, 3 cases and 3 deaths were reported from Rock Island; the state board of health at Des Moines, September 18, had received reports of 43 cases throughout the state, 19 of which had occurred at Davenport and vicinity, where the disease was epidemic. Other towns and counties in the state reporting cases were Deep Creek, Clinton County, Lynn, Plymouth, Fayette and Monona counties; Castana reported 3 deaths, with 1 case under quarantine; Knoxville, Marion County, reported several cases in the county; Schleswig had 1 case, September 15; Waterloo had 1 death, September 16; Kansas City, Mo., September 14, had 3 cases; September 15, Montana reported no cases since August 18. In Nebraska, September 14, 5 suspected cases had been reported to the state health authorities from Hebron, 2 from Dawson, 1 from Schuyler and 1 from Johnson; at Omaha there had been but few cases, and no alarm was felt. In New York City names and address of infantile paralysis patients are published so that parents may protect their children. The plan has worked well, it is said. Pennsylvania reported 1 case from Waynesboro, September 12, and 1 from Mahanoy City, September 14. There had been 107 cases in the state during August.

FOREIGN

Deaths in the Profession Abroad.—**F. Wullyamoz** of Lausanne, a pioneer in roentgenoscopy and surgery under screen control before the war, aged 40.——**R. Alvarez**, chief of the psychiatric clinic at Cordoba, Argentina.——**A. Biondi**, docent of medical pathology at the University of Naples, aged 71. From recent casualty lists in France: **P. Bournet, Bornet, Tardif, Zagrewski, Dagès, M. Gohier, Chambrelent** and **P. Patriarche**, all aide-majors.

New Medical Journal in Argentina.—The bimonthly, *El Monitor*, Santa Fe, Argentina, has appeared in a journal of forty-four pages divided into two parts, one devoted to medicine, surgery, hygiene and pharmacology; the other is given up to articles on chemistry, industrial hygiene and veterinary questions. The editor in chief is Prof. E. Escobar, who is director of the service for children's diseases at the public hospital and also of the National Industrial School. The journal aims to be a bi-monthly review of science and industry. The annual subscription is about $6.

The Gasoline and Coal Question in the Netherlands.—One of the subjects mentioned in the president's address at the recent annual meeting of the Netherlands Medical Association was the scarcity of gasoline and coal. The outlook for gasoline is dark, the committee in charge of this matter reported. The state "benzine-control commission" admits that the conditions are cause for concern, but that it was hoped to be able to supply physicians with about 40 per cent. of the amount they used in normal times. The new price regulation by Germany has cooperated in the grave condition, it is said. The state petroleum commission announces that physicians can be supplied at present with 8 or 10 liters of petroleum for professional use, but stricter regulations are impending. The local (the Hague) coal-control commission is giving out small units of coal for various places, and among them are physicians' offices and waiting rooms. The quantities thus taken are to be credited to the amount set aside for physicians, to be estimated later. After October, the gas and electricity supply is to come under the control of the coal-supply commission. As to obtaining fodder for horses owned by physicians, nothing had been settled at the time of the meeting.

LONDON LETTER

London, Sept. 1, 1917.

The War

DRASTIC FOOD CONTROL

The measures of food control taken have from time to time been previously reported in The Journal. Some of a most drastic character have just been taken, greatly extending the control beyond anything previously done. The object is to prevent "profiteering" (a term which has come into vogue since the war, and means making undue profits in consequence of opportunities furnished by the war). The maximum price, both wholesale and retail, at which the most important foods may be sold is now laid down by law according to schedules. Thus the maximum price at which Argentine, Canadian, American and Irish creamery butter may be sold is $41 for 112 pounds. This, of course, is the wholesale price. Any person other than the importer or maker may not sell butter at a price which exceeds by more than $2 a hundredweight the price paid by him or the first-hand price in force at the time, whichever is the lesser. With regard to retail sales, it is provided that no person shall sell butter at more than 5 cents a pound in excess of the cost to him, but an additional cent may be charged for giving credit or for delivery. From the terms of this order it may be assumed that the retail price of butter will vary from about 50 to 59 cents a pound. This is practically its present price, so that any advantage the order may have for the consumer will be in preventing a further increase in price. The cheese order applies only to wholesale prices of British-made cheeses. They must not be sold by a maker at prices exceeding $29 to $33 a hundredweight, according to the variety of cheese. No person other than the maker may sell at a price in excess of whichever is the lesser of the two following: (*a*) $1.50 above the price paid, plus the cost of transport, or (*b*) $2.50 above the first-hand price. The price of meat is similarly regulated. Beef now costs 42 cents a pound and mutton 36 cents. Bread now costs 24 cents for a 4-pound loaf, but according to a regulation about to come into force this price will be reduced to 18 cents. The price of wheat does not allow bread to be sold at this rate, and the government will bear the loss, which is estimated at about $100,000,000 per annum. This measure to keep "the staff of life" at a fixed price is designed to benefit the very poor, persons who unlike munition workers and others, are not receiving greatly increased wages in consequence of the war.

CIVILIAN PHYSICIANS IN THE ARMY

Sir Alfred Keogh, Director-General of the Army Medical Corps, proposes to establish a branch to deal with questions directly affecting territorial and temporary medical officers. It will be able to collect and collate information on the many problems raised by the incorporation of so large a number of civilian physicians in the Army Medical Service. The fact that they now constitute about eleven twelfths of the service is in itself sufficient to justify the new departure. It is understood that the intention is that the staff of the branch shall include a territorial and a temporary officer having recent experience of war conditions.

Bubonic Plague in the Port of London

The steamship *Matiana*, from Bombay, arrived at Gravesend, August 13. On the voyage, between July 14 and 28, there were nine cases of bubonic plague, with six deaths, among the crew, all natives of India. The bodies were buried at sea. Three convalescent or more chronic cases were taken off at Gravesend and removed to hospital. The crew was kept under medical observation, and another case occured which resulted in the death of the patient in hospital. The vessel called at Falmouth, August 11, but no cargo was discharged and no passengers were landed at that port. The ship remains at the official mooring station off Gravesend, and the cargo was discharged into lighters under supervision of the health officer of the Port of London sanitary authority, who is taking all necessary precautions.

The Campaign Against Venereal Disease

Considerable progress has been made with the organization of measures for the free diagnosis and treatment for persons suffering from, or suspected to be suffering from, venereal diseases. Between 140 and 150 hospitals in England and Wales have expressed their willingness to participate in the scheme of local authorities, and although in a few instances the authorities of important hospitals have been reluctant to inaugurate during the war any fresh arrange-

The Propaganda for Reform

In This Department Appear Reports of the Council on Pharmacy and Chemistry and of the Association Laboratory, Together with Other Matter Tending to Aid Intelligent Prescribing and to Oppose Medical Fraud on the Public and on the Profession

ESKAY'S NEURO PHOSPHATES

Report of the Council on Pharmacy and Chemistry

For the information of the profession the Council has prepared and authorized for publication the following report on Eskay's Neuro Phosphates. W. A. Puckner, Secretary.

Eskay's Neuro Phosphates (Smith, Kline & French Co., Philadelphia) is offered to physicians under the claims that it contains alcohol, 17 per cent., and sodium glycerophosphate, 2 grains, calcium glycerophosphate, 2 grains, and strychnin glycerophosphate, 1/64 grain, in each dessertspoonful. It is called a "Nerve Tissue Reconstructive," and its advertising claims are based on the discredited theories that certain disorders are due to a deficiency of phosphorus in the nerve structure of the body, and that glycerophosphates are assimilated more readily than ordinary phosphates. This assumption was based on the knowledge that the lecithins, which form a part of the nerve structure, contained the glycerophosphate radical in the molecule. In line with this, Smith, Kline & French Co. aver:

> "Eskay's Neuro Phosphates is of marked value in many acute and chronic conditions, in nervous exhaustion following mental and physical strain, neurasthenia, paralysis, anemia, tuberculosis, marasmus, debility and wasting diseases generally, and the nerve-weakness of the aged. It is particularly useful in convalescence from acute diseases and in the nervous condition following la grippe."

In its report on "The Therapeutic Value of the Glycerophosphates" (*The Journal, Sept. 30, 1916, p. 1033*) the Council pointed out that the therapeutic use of the glycerophosphates was based on the assumption that the inorganic phosphates cannot supply the body's needs of phosphorus or that the use of organic compounds "spared" the system the necessity of making such synthesis. The report presented evidence to show that the glycerophosphates are not absorbed as such, but that they are split into inorganic phosphates before absorption. The Council showed that there was convincing evidence that the animal organism synthesizes its complex organic phosphorus constituents from inorganic phosphates, and that organic phosphorus is of no more value as a food than inorganic. Despite this the Neuro Phosphates advertising makes use of the fallacious assumption regarding the action of the glycerophosphates.

Pleading for the particular mixture represented by the proprietary, it is asserted that:

> "Sodium glycerophosphate is of special value in neurasthenia, Addison's disease, phosphaturia and phthisis."

and that calcium glycerophosphate "is employed in bone fracture, rachitis, tuberculosis and various wasting diseases."

The phosphorus content of 1/64 grain of strychnin glycerophosphate is ridiculously small. Yet it is asserted that this strychnin salt is of superior value because it combines the effects of strychnin with a "food-like form of phosphorus." Eskay's Neuro Phosphates has an acid reaction which is capitalized, thus:

> "Experiments have shown that the acid glycerophosphates are more rapidly absorbed and are more efficient than the neutral salts."

And as a further illustration of extravagant claims:

> "As a glycerophosphoric acid in the form of lecithin is normally present in spermatozoids, it is but natural that the glycerophosphates should exhibit aphrodisiac effects (as has been observed), but this result does not seem to obtain in all cases."

Is this a clumsy attempt to exploit this "nerve phosphate" as a "lost manhood" cure?

The Council held Eskay's Neuro Phosphates ineligible for New and Nonofficial Remedies because unwarranted therapeutic claims are made for it and because the administration of strychnin, calcium, phosphate and alcohol is not conducive to rational therapeutics, particularly when such a mixture is marketed under a name which indicates but one of its constituents.

K-Y LUBRICATING JELLY

Report of the Council on Pharmacy and Chemistry

Because of inquiries received, the Council has authorized publication of the following report declaring K-Y Lubricating Jelly inadmissible to New and Nonofficial Remedies.

W. A. Puckner, Secretary.

K-Y Lubricating Jelly (Van Horn and Sawtell, New York), originally advertised as a lubricant for instruments and the hands, is now also recommended as a therapeutic agent. If the claims for "K-Y" were limited strictly to such effects as result from the purely mechanical properties of a lubricant, it might be held that it would not come under the purview of the Council. The preparation, however, while introduced as a lubricant, is now offered for a broader field of use, and the manufacturers make claims which are not supported by any evidence available to the Council. Evidence the following, taken from a circular that accompanies the package:

> "K-Y allays smarting and burning at once through its pronounced soothing and cooling effects, and thus makes an admirable dressing for burns."
>
> "Many physicians make a practice of anointing the bodies of their measle and scarlet fever patients with 'K-Y', in this way affording gratifying relief from itching and irritation, and effectively preventing dissemination of infectious material."

And this from another circular:

> "I had one of the most troublesome cases of pruritus vulvæ that I had ever seen. I guess I must have tried everything and the case had been referred to me by another man, who had previously tried everything, including cauterization. Well, one day I was examining her, and of course K-Y on the speculum—the irritation seemed to quiet down, and the following day she said she felt no effects from it at all. Then later on, it returned, and I couldn't imagine what had done so much good, unless it could have been the lubricant, so I told her to buy a tube, which she did. Every once in a while she has a return of it slightly, but she just applies K-Y and clears it all up."

The manufacturers state that they do not know why K-Y is so soothing, but suggest:

> "Possibly the cooling action of the combination, and the effect of the 4% boric acid contained, are factors that enter. Be all that as it may, the fact certainly remains that oftentimes, after other local measures fail, 'K-Y' Lubricating Jelly gives relief."

Elsewhere it is claimed to be germicidal, and to give relief in other conditions, thus:

> "Diabetic and uremic irritations, not only of the genitalia, but of other parts, have been found fully as amenable as pruritus vulvae to the soothing influence of 'K-Y' Lubricating Jelly, especially if the previous application is removed with water every time a new one is put on."

The foregoing citations are obviously intended largely for the public, and make it plain that "K-Y" Jelly is not in the class of nonmedical and harmless external applications; on the contrary, these claims tend to create the impression that the spread of measles and scarlet fever can be *prevented* in the stage of desquamation. To place such statements in the hands of the patient supported by the tacit endorsement of a prescription is to create a false and dangerous sense of security and to lead to a failure to observe other and more important means of preventing dissemination of these diseases.

The Council held K-Y Lubricating Jelly in conflict with Rules 1, 4, 6 and 10, and authorized publication of this report.

The Medical Officer Must Be an Administrator.—The army medical officer of today must not only be a trained scientist but a capable administrator. In other words, his duties in the zone of advance, the line of communications, and the interior, are in every respect as onerous and exacting as those of the line or engineer officer, and the story of his accomplishment, in the present war, will, when told, make a brilliant record.—Lieut.-Col. C. C. McCulloch, Jr., U. S. Army: The Scientific and Administrative Achievement of the Medical Corps of the United States Army, *Scientific Monthly.*

Correspondence

OBSERVATIONS OF MEDICAL SERVICE ABROAD

To the Editor:—I have recently visited many European military hospitals, including first aid stations, clearing hospitals, and third line or base hospitals. In many places I have found American surgeons actively engaged and doing splendid service. In several large well-equipped hospitals the service is light and many beds are empty. In such cases the surgical staff is for protracted periods more or less inactive.

It is to be feared that at first men who had come from large hospitals in America, having enjoyed an active daily service normally, were surprised, not to say disappointed, to find time hanging heavily on their hands. This feeling was soon corrected and surgeons are now interesting themselves in the solution of problems of various types which are constantly developing.

Briefly the military surgeon of today must be forewarned that war is not waged for the purpose of filling hospitals, and he must be fully reconciled to wait patiently under his assignment. After an advance resulting in a large casualty list, he will lead a strenuous life for a more or less protracted period. Empty beds with idle ambulances in large number are not a regrettable feature of military life.

It should be further clearly understood that men who have specialized and who are highly trained will find their services acceptable at many points. But the average man, however capable, must win his spurs under new conditions before he can hope to become conspicuous in a foreign environment.

Thomas W. Huntington, M.D.,
Hotel Excelsior, Rome, Italy.

[Editor's Note.—Dr. Huntington (of San Francisco) is a member of the American Red Cross Commission to Italy. This committee consists of Mr. George F. Baker, Jr., chairman; Mr. John R. Morron, Dr. Victor G. Heiser, Dr. Thomas W. Huntington and Mr. Nicholas F. Brady.]

DRAFTING PREMEDICAL STUDENTS

To the Editor:—The question of the exemption of freshman medical students is one on which there has been much discussion, and perhaps the readers of The Journal would be interested to know the attitude of one who has been drafted, and called into service.

The Journal has been for some time my constant companion in my hours of leisure and in these times, at least, my consolation that I might find at the last moment some hopes of continuing my medical work next year.

The last number, that of September 15, contained a very encouraging letter from the dean of the University of Virginia, department of medicine, which prompted this letter. He has stated my case, as well as that of many more in the same predicament.

We were told when the war first broke out between the United States and Germany that medical students would not be subject to call in case of draft and that "premedics" might be considered as medical students. When the draft became a reality, and the exemption lists included no clause for us we were still told that it was only diplomacy that kept the government from declaring a class exemption of medical students. Some of us rather doubted this and spoke of entering officers' training camps; then the dean of the school of medicine came out with a letter from a high official from Washington stating for a fact that we were free. Now many of us had already had military training in various lines and could have easily earned our commissions but were told that we could better serve our country by staying in school and then giving her a trained instead of an untrained service. Some of the boys disregarded this and went to the camps; they are now going about with silver bars on their shoulders; proud that they were counted as worthy to be officers in the great National Army, while we who thought we were best serving our country by staying in school are going about with our hands on our hearts wondering what will be done with us next. In fact some of us have ceased wondering as we are called in the first draft. It is not as though we were trying to avoid the draft or hiding under the banner of our college, afraid to go. I venture to say that if the plain truth had been told us in the first place there would not have been one of us who would not have been in some branch of the service before the day of registration.

An objection raised is that the medical schools would be crowded with slackers and draft dodgers of every description. This immediately loses its significance when we realize that every medical school requires some premedic work and that premedic work no one would take who did not intend to pursue the further study of medicine. The fact that we entered last September in the premedical department of the university proves that we had then determined to study medicine, and hence according to all justice should be considered medical students, and exempt from draft under that clause.

It is not as though the government had no redress for those who tried to evade her orders by entering medical schools at this time; the questions of standards of scholarship and attendance could be brought to bear on all medical students in the freshman year at this time. The government could very easily require a certain minimum grade and a minimum standard of attendance, all those falling below either of which to be at once liable for call and military service. This could be very easily accomplished by utilizing the professors of military surgery that the government assigns to the various medical schools. So there is absolutely no excuse for such a drastic, not to say unjust and outrageous, procedure on the part of our government.

Furthermore, the demand for doctors at the end of the next four years is going to be just as great if not greater than it will be at the end of the next year and two following. This has been amply proved by authentic statistics available to all those who care to take the time to peruse the recent editions of the daily papers or, for the profession, the last three or four editions of The Journal. Under these circumstances it seems not only unjust but absolutely prohibitive and criminal that the government at this time should undertake to jeopardize the future healthful well-being of this country as well as those across the sea by exposing these young men to the dangers and possible casualties, not to speak of the many fatalities, of this war.

This does not exhibit on our part any lack of patriotism or love of country, but rather shows that we have the great welfare of the country at heart for the future, and should this war last—which God forbid—beyond the next four years, the need of physicians would be an obstacle that would be absolutely insurmountable. At any rate, the next two years would fit us to be of infinitely more value as assistants in the Medical Corps than we are now as riflemen. Any one can learn to shoot a gun in an hour but it takes much longer for one to acquire skill in manipulating a scalpel.

Phillip J. Beyhan, Chicago.

"RED CROSS" BASE HOSPITALS

To the Editor:—My attention was directed to a contribution by Dr. Joseph B. DeLee (The Journal, Aug. 24, 1917, p. 665), advocating the construction of military hospitals in France in the shape of a cross with roofs to be painted in red color. In view of the deliberate bombing of an American base hospital by German flyers and the resulting killing and maiming of innocent "noncombatants," the doctor's plan would produce the very opposite effect he aims at. The best plan is to make all sanitary formations and institutions as invisible as neutral tints can render them. In addition it would be wise to disperse the buildings of large institutions over a fairly wide area and to place them under the shelter of natural foliage, or artificial for that matter, schemes employed to hide artillery batteries from aerial reconnaissance. In view of the fact that antiaircraft guns are effective only when the machines fly at moderate height we may even have to go farther and construct hospitals under bomb proofs.

Time was when the emblem of the Red Cross stood for the humanitarian in warfare, but today it is a beautiful target for the enemy's policy of frightfulness. In the same sense the putting on of a brassard by sanitary personnel on the firing line would only tend to increase their mortality and casualty rate. I have in my field library a book entitled "Rules of Land Warfare." I read it before my last promotional examination some time ago, but I have not opened it since the present mobilization for obvious reasons.

Gustavus M. Blech, M.D.
Major, N. G., Ill., Camp Logan, Houston, Texas.

Queries and Minor Notes

Anonymous Communications and queries on postal cards will not be noticed. Every letter must contain the writer's name and address, but these will be omitted, on request.

EOSINOPHILIA

To the Editor:—1. What is the significance of eosinophilia? 2. What is its diagnostic and prognostic significance in arthritis, periarthritis and periostitis of the spine? 3. Does it occur in malignant diseases? 4. Please give references to the best recent books and articles on infections of the spine.

E. W., Evansville, Ind.

Answer.—1. Eosinophilia is physiologic in childhood, the average increase being about 1 or 2 per cent. above the normal adult finding. There are some racial distinctions. The natives of southern China show between 15 and 20 per cent. of leukocytes as eosinophils. Pathologic eosinophilia occurs in splenomyelogenous leukemia, in sarcoma, osteomyelitis, osteomalacia, chlorosis, secondary anemia following infection, extirpation of the spine, chronic splenic tumors, bronchial asthma, emphysema, pemphigus, eczema, psoriasis, urticarias, leprosy, herpes zoster, and other skin diseases associated with toxic agents. They are also sometimes found increased in scarlet fever, acute rheumatism and malaria, as well as sometimes in syphilis, gonorrheal infections and in forms of ovarian diseases with the exception of cancer. Any parasite, from pin worms to uncinarias, may cause an eosinophilia which is not necessarily constant, and does not bear any relation to the severity of the infection. 2. Its relation to infections of the bones would be of the same character as its relation to the infections and bone diseases mentioned in the previous answer. 3. No great weight could be attached to eosinophilia in making a diagnosis of malignancy. 4. The following are recent articles on infection of the spine:

L. P. Gould: Osteomyelitis of the Spine, The Lancet, 1917, **1**, 374.
D. N. Eisendrath: Osteomyelitis of the Spine, American Surgeon, 1917, **65**, 147.
A. Kinder: Osteomyelitis of the Spine, New Zealand Medical Journal, 1915-1916, **14**, 215.

CHOICE OF ANESTHETIC—RESPONSIBILITY

To the Editor:—(a) Please inform me who should make the choice or selection of an anesthetic for a hazardous surgical case, the expert anesthetist or the operating surgeon?

(b) On whom does the responsibility rest if a patient should die from an anesthetic, on the operating surgeon or on the expert anesthetist?

Thomas G. Allen, Philadelphia.

Answer.—(a) The operating surgeon.
(b) On the operating surgeon.

Tetanus in Court Plaster.—Investigation by the Hygienic Laboratory of the Public Health Service following press reports of infection with tetanus from court plaster, resulted as follows, as given in *Public Health Reports*, September 7: Out of thirteen specimens examined, two were found to be contaminated with tetanus bacilli. The specimens examined were procured from drug stores in the original packages as they go to the consumers. It was found that court plaster is not clean in the surgical sense, but whether the contamination with tetanus bacilli occurred during the process of manufacture through infected ingredients will be the subject of another investigation. It is not believed that the contamination was intentional. The report of the laboratory investigation is given in full in the publication referred to.

Book Notices

Physical Chemistry of Vital Phenomena, for Students and Investigators in the Biological and Medical Sciences. By J. F. McClendon, Assistant Professor of Physiology in the University of Minnesota. Cloth. Price, $2 net. Pp. 240, with 30 illustrations. Princeton: Princeton University Press, 1917.

Physical chemistry, that lusty infant prodigy, offspring of the union of physics and chemistry, has already come in many instances to the assistance of the practitioner, giving aid in diagnosis and helping in the explanation of physiologic processes. One has only to recall the most recent innovations of the determination of the hydrogen ion concentration of the blood and spinal fluids, the diagnosis of syphilis by the colloidal gold test, or the distinguishing of epidemic cerebrospinal meningitis from tuberculous meningitis by the cataphoresis of the proteins of the spinal fluid. Hence a book of this title should attract the interest of practitioners and students alike. This book, however, makes no pretense to having been written for clinical men. It is rather intended for advanced students who already understand much about the subject. It contains many interesting facts for such students, and quite a long and useful literature list at the back in which both titles and authors are cited. It treats of such things as osmotic pressure, adsorption, hydrogen ion determinations, surface tension, enzyme action, permeability of cells, anesthesia and narcosis, cytolysis and disinfection, ameboid motion, muscle contraction, oxidations, artificial parthenogenesis and cell division. Truly an appetizing bill of fare, if only well cooked and seasoned!

But alas for the "if." It is not well cooked; much of it, indeed, is quite raw, and the seasoning has been generally omitted, so that even a robust appetite will not make it all palatable. This is not saying that there is not much that is good in the book and many facts that are stimulating and instructive. The chapter on the method of hydrogen ion determination is decidedly worth while; and the book is certainly no worse than many German books on similar lines. Perhaps the title makes us expect too much, and in the outcome we have so little—so little except words, and of these there are so many and such long ones! There is hardly a properly formed scientific statement in the first chapter. It is full of conclusions and interpretations stated as if they were facts, and of conclusions which do not follow from the premises. Throughout the book there is a scarcity of objectively described facts. Almost never do we find a clear, simple statement of what the objective facts really are; always these facts are obscured by interpretations, or the interpretations are substituted for them.

The author, in accordance with the prevailing style of the hour, attempts to explain all the phenomena of life by inventing what he calls a plasma membrane and putting it around a colloidal solution and calling it protoplasm. Since he is the inventor of this membrane, it is his privilege to make it as ingenious as he can. The main differences between the theories of the physical-chemical zoologists and physiologists at the present time consist in the ingenunity of their imaginary membranes. If only these membranes are sufficiently complex, it becomes possible to explain all the phenomena of life by means of them. If any new facts are discovered which the old membrane cannot account for, it becomes the simplest thing in the world to take that membrane off, to devise a new one with more modern improvements, wrap it about a colloidal solution of a nondescript character, and there you have protoplasm! This membrane has pores in it so graduated in size or otherwise so constructed that they let through positive but not negative particles, and, behold! there is the explanation of the electrical phenomena of protoplasm. Or sometimes the pores close, and then you have anesthesia. And so on. To explain how this is all possible it is only necessary to fall back on surface tension. Surface tension explains all things. This is a perfectly safe refuge and one calculated to satisfy the greatest doubter, for no one understands what surface tension may be doing in such complex systems, and almost no one understands it even in the simplest cases. In saying this we do not aim especially at the author of this book, for he has only put together the publications and conclusions of other men; but we are aiming at the whole glib, superficial school of biologists, who pretend to solve fundamental problems of the greatest complexity.

This book is typical of much of modern biology. It is not possible to say about it anything worse than this. Biology is in a period of inflation. Real values are obscured. Worthless properties are being worked as fabulously rich mines, but the ore contains only a trace of real metal. A little glitter and some mathematical formulas lead astray all but those who have been already once deluded. Words take the place of real explanations; we have purely verbal solutions of the most abstruse problems. These words lull us to sleep; they form a wire entanglement, serving to keep out truth and light.

One comes back from reading a book of this character, and most books on this subject, with the feeling of having been wandering in a terrible morass. Some of the ill smelling mud still clings to one. "Permeability" and "adsorption" are words covering a multitude of scientific sins. This must truly be the red light district, the demi-monde of science, which intoxicates and ruins its habitués. This realm of biology is truly that demiscience which Paul Shorey anathematizes. Words juggled from one meaning to another; conclusions unrelated to their premises; a trackless waste—the biologic authors wander through this series of sink holes, struggling out of one only to fall into another, and the reader, if he is not sure of foot and alert of eye, falls with them.

THE TREATMENT OF TABETIC ATAXIA BY MEANS OF SYSTEMATIC EXERCISE. By Dr. H. S. Frenkel, Medical Superintendent of the Sanatorium "Freihof" in Heiden (Switzerland). Second English Edition by L. Freyberger, J.P., M.D., M.R.C.P. Cloth. Price, $3 net. Pp. 209, with 130 illustrations. Philadelphia: P. Blakiston's Son & Co., 1917.

The first edition of this book, which is an adaptation and not a translation of Dr. Frenkel's book, appeared in 1902. In the second edition, revised by Dr. Freyberger, "redundaces" have been removed, a few unnecessary illustrations taken out, and the remainder partly regrouped. "Notes on the medical treatment that is often required during Frenkel treatment" are added by Dr. Freyberger.

A number of changes in the make-up of this edition reflect credit on the former one. In size it conforms more readily to standard volumes; the illustrations are not so clear. The legends of some of the diagrams which were left untranslated in the former edition are rendered into English. Some of the measurements of diagrams are omitted, and in some errors appear, as 9 inches for 63 ct. Certain important statements marked by italics in the former edition are left unemphasized.

The text, as in the former edition, presents a clear and comprehensive exposition of a method of treatment which deserves wider recognition and more general application. Frenkel introduces in a general part his description of the method by broad definitions of coordination, and ataxia. He reviews the theories of the causes of ataxia, and describes and upholds the sensory theory. A full description of methods of examining the sensibility is given, and an extensive description of muscular hypotonia, which plays so important a rôle in the disability of the tabetic, is presented.

In a special part, the mechanism of movements of the human body is described, so that the rationale of the following directions for treatment is established, and the exercises may be followed logically and clearly. The practice rooms and apparatus, which are very simple, are described, and the exercises classified, minutely explained and commented on freely. The large number of illustrations assists in making the book one which, if read, cannot but lead to a clearer understanding of tabetic ataxia by the general practitioner, and to the more consistent employment of reeducational methods by specialist and general practitioner as well.

It is impossible to omit a criticism of the more or less parasitic notes on the medical treatment of tabes dorsalis which are added by Dr. Freyberger. Among other things, the author demands that before the case should be definitely pronounced nonsyphilitic, an examination of the spinal fluid should prove "an entire absence of spirocheta pallida," whereas nothing is said of the cell count, the colloidal gold chlorid test, or globulin tests which, in contrast to the *Spirochaeta pallida*, are so frequently found pathologic.

Just why intravenous or intramuscular injections of antisyphilitic medication are interdicted during the period of Frenkel treatment is left as great a mystery as why we should defer Frenkel treatment until "the effects of the antisyphilitic treatment are beginning to be well established."

The author states that the following preparations will be found useful in the preliminary treatment, and he includes with salvarsan and neosalvarsan such agents as collargol, sodium and gold chlorid, and various proprietary combinations, as Enesolum, Iodglidinum, and Ioha. Although he states that salicylate of mercury is the best substitute for mercurial inunctions or injections of mercurial oil, he describes neither one.

The author's preference for proprietary remedies is seen in his collection of choice drugs for symptomatic treatment: Trivalium, Arsentriferrolum, Bromo-lecithinum, Diplosalinum, Hedonalum, etc. Combretum for morphinism occupies as much space as is devoted to salvarsan.

Nothing at all is said of intraspinal treatment. Apparently Freyberger does not believe that all cases of tabes dorsalis are syphilitic, as he says that "iodides are excellent tonics in nonsyphilitic cases of tabetic ataxia."

An adequate criticism of this chapter would take up more space than the chapter itself, which might better have been omitted.

Habit.—Habit keeps us all within the bounds of ordinance, and saves the children of fortune from the envious uprisings of the poor. It alone saves the hardest and most repulsive walks of life from being deserted by those brought up to tread therein. It keeps the fisherman and the deckhand at sea through the winter; it holds the miner in his darkness, and nails the countryman to his log cabin and his lonely farm through all the lonely months of snow. In most cases, by the age of 30, the character has set like plaster, and will never soften again.—William James.

Social Medicine, Medical Economics and Miscellany

BARON LARREY, THE FRENCH ARMY SURGEON

HOWARD D. KING, M.D.
NEW ORLEANS

Seventy-five years have elapsed since the death of Baron Larrey, surgeon-in-chief of the armies of Napoleon. In the annals of military surgery Larry will forever stand preeminent as a leader. In this hour of stress and conflict a brief biography to the famouns French army surgeon should prove timely.

D. J. Larrey was born in 1766, at Beaudéan, near Bagnères-Adour, Haut Pyrénnes. His parents were in modest circumstances, but of good peasant stock. At the age of 13, with very little previous education, he was sent to study under his uncle, who was surgeon and professor of surgery of the General Hospital at Toulouse, and also an associated correspondent of the Royal Academy of Surgery at Paris. At Toulouse under the guidance of this relative he passed through the usual medical courses. In 1787 he went to Paris, and was in this city only a few days when he received the appointment of assistant surgeon in the navy, a post which he accepted only because it enabled him to indulge his natural taste for traveling. Larrey was ordered to join his ship at Brest, but his resources were so low that he walked from Paris to that port, and on his road he visited Laval, sought out the house where Ambroise Paré, the father of French surgery, lived, desired to see his chamber, and, yielding to the delusion of a warm imagination, almost fancied his great predecessor to be present.

APPOINTMENT AS SURGEON IN NAVY

On his arrival at Brest he was subjected to a second examination, and passed in such a distinguished manner that, contrary to all precedent, he was appointed full surgeon at the age of 21, to a small frigate, *La Vigilante*. The ship being delayed in port during the winter he employed himself in giving lectures to the young students in anatomy and surgery. In the following April the ship sailed for Newfoundland, to protect the cod fisheries, and to cruise off the coasts of North America. This voyage was without event, save that on reaching Brest in 1788 the provisions had run so low that each member of the crew was reduced to a daily ration of 4 ounces of biscuit and a bottle of putrid water. Again on shore Larrey immediately set off for Paris, and studied clinical surgery under Sabatier and Desault, the latter of whom he speaks of as a surgical genius, and as one to whose instruction he felt greatly indebted.

At this critical period the first clouds portending the French revolution were fast gathering in the political horizon, and civil dissensions had already risen to such a height in Paris that several battles were fought in the garden of the Tuilleries, at the Bastille, and in the Champs de Mars. A large number of the wounded combatants came under the immediate care of Larrey, who thus early observed that delay in amputation after certain gunshot wounds caused an increase in tetanus. He also gave a great deal of his time to the study of the problems of infections and bone necrosis.

CREATION OF AMBULANCE VOLANTE

The invasion of France by the continental powers shortly following, he was appointed full surgeon to the Army of the Rhine, commanded by Marshal Luckner, and he joined on April 1, 1792. It was in this campaign that he observed the faulty arrangement of the ambulance service, which it was customary to station a league in the rear of the soldiers, so that the wounded were left undressed and unattended till after the battle, when they were removed to the regimental hospitals. Owing to the great obstruction of the roads by baggage and the movements of the troops, it was often days before the wounded received surgical assistance, and as a consequence many perished for want of timely first aid. Larrey proposed to General Custine to establish an *ambulance volante*, or a means by which the wounded might receive first aid on the battlefield. This reform produced a great sensation in both military and medical circles. At the close of the campaign on the Rhine the military surgeons were highly spoken of by General Beaurharnios, in his despatches to the Directory, and Larrey was ordered to Paris to complete his *ambulance volante*, and to adapt and introduce it into the other armies of the Republic.

LARREY'S SERVICE IN EGYPT

In the year 1797, after having seen service in Spain, he received orders, apparently at the request of Napoleon, to set out for Italy, and to establish the *ambulance volante* in that army; but hardly had he arrived at headquarters when the peace of Campo Formio was signed. Next Bonaparte committed the great military error of transporting a French army to Egypt, at which time he demanded that Larrey join the expedition. In this position Larrey earned the high regard of the Corsican. He was with Bonaparte when he crossed the Red Sea and it was at this time that Larrey nearly lost his life by drowning.

AN OFFICER OF THE LEGION OF HONOR

The peace of Amiens saw Larrey back in France, and on his arrival in Paris he found Napoleon first consul, who not only ordered Berthier, in a public document, to express his satisfaction at the zeal and manner in which he had fulfilled his public duties, but confirmed all the medical officers he had promoted in Egypt, named him surgeon-in-chief to the Consular Guard, and presented 1,500 francs to Madame Larrey. On Napoleon assuming the purple Larrey was one of the first named of the Legion of Honor. Bonaparte afterward created him an officer of the Legion, presenting the decoration with his own hands. Following this appointment Larrey was made Inspector General of the French Army. But he was to be still further honored, for after the battle of Eylau he was promoted to the rank of Commandant of the Legion of Honor, Chevalier of the Iron Crown, and, after the battle of Wagram, he was made Baron of the Empire, with a pension of 5,000 francs. At this juncture his good fortune ceased, and on the first deposition of the emperor he proposed to retire with him to Elba, and to share his banishment, but Napoleon opposed this mark of devotion in his faithful friend. "You belong to the army," he said, "and must continue with it; but I part from you with the deepest regret."

Almost immediately after his escape from Elba, Napoleon despatched a messenger to the Tuilleries for Larrey, and after displaying the most touching regard and satisfaction at seeing his old friend, declared, "I hope soon to have the opportunity of recompensing you for the sacrifices you have made, and for the services you have rendered the wounded." One of those *coups de theatre* with which the returned emperor attempted to support his power was summoning deputies from the different provinces to receive a tricolored standard. Larrey was among those elected for the Haut Pyrénnes, and the emperor selecting him from the rest, placed the emblem of French military glory in his hands, expressing his delight in entrusting it to a man who honored humanity by his disinterestedness and courage, and whom he had often seen in the parching deserts of Lybia giving to others the water and wine he greatly needed for his own support.

When the preparations for opening the fatal campaign of 1815 were completed Napoleon sent General Drouet to Larrey with orders to join the army, and more especially to direct the ambulance of the guard, and to be near his person. It was at Waterloo after the tide of battle had turned against the French, and the charges of the British cavalry had nearly reached the French ambulances, Napoleon still remembered his friend, and sent one of his aides-de-camp to point out to Larrey a cross road by which he might escape. He had not proceeded very far when he was chased by the Prussian cavalry, but was fortunate to outdistance his pursuers. In his flight he was thrown from his horse to the ground where he lay for some time unconscious. On recovering consciousness he again attempted flight but fell in with the Prussian cavalry a second time and was made prisoner at Sambre. The Prussians stripped him of everything but his redingote, and in this forlorn state he was happily mistaken for Napoleon, and carried with his hands tied behind him to Commandant Bulow, by whom he was recognized. Larrey had saved the life of Prince Blucher's son, who had been seriously wounded, and made prisoner during the German campaigns, and this act of kindness being remembered Larrey was now treated with much consideration, had his wounds dressed, more cleanly and commodious quarters assigned him, and afterward obtained permission to proceed to Brussels, in order that he might succor his wounded countrymen.

THE DOWNFALL OF NAPOLEON

After the downfall of Napoleon at Waterloo Larrey suffered many humiliations at the hands of the Bourbon dynasty. He was deprived of his office of inspector general, and all of his pensions cut off. He was retained, however, as surgeon of the guard, for fear, as he alleged, that the troops would mutiny at his removal. From 1815 to 1818 his position was most trying, for among his misfortunes he lost his mother, and a favorite brother, a surgeon at Nismes. In 1818 his fortunes appeared to be on the mend. The pension of 3,000 francs granted him by Napoleon for services at Lutzen, Wurchen, and Wagram was restored to him by unanimous decree of the legislative assembly. The declining years of his career, also, were cheered by many honors and distinctions. The king of the Belgians invited him to organize the ambulance of his army, while Louis Phillippe granted him the decoration for his services to the wounded in the three days of July. He also made trips to Italy and England. His last official service to the French government was an inspection of the French hospitals at Algeria. On his return from Africa he set off for Paris to make his report to the governmen, but died en route at Lyons, July 25, 1842.

HIS SERVICE TO MEDICINE

Larrey's claims to distinction as a surgeon are great. That he was admirably fitted for the high professional offices he attained is today admitted by the whole surgical world. Up to the day of his death no one ever held a higher place as a military surgeon. It is impossible to study his works without being convinced of his sound sense and good judgment, and the rapid manner in which he interpreted disease and applied the resources of his art to the relief of the patient. On account of his boldness, which was coupled with a most skilful technic, Larrey enriched surgery with many and far reaching advances.

Before the last Revolutionary Wars there were scarcely more than two or three examples of amputation at the shoulder joint, an operation first performed by Ledran. This operation, however, Larrey frequently and repeatedly performed, and even extended, by removing large sections of the shoulder and scapula, and with such success that out of 111 cases, ninety-seven were cured. Modern hospital records show no greater achievement than this wonderful list of successes. The facility with which he performed this operation was quite wonderful, the limb being removed in two minutes, and the loss of blood negligible.

Up to Larrey's time it was the custom to delay amputations until the line of demarcation had formed. The impatience of Larrey refuted the wisdom of this surgical dogma, and with the French army surgeon it was always a case of now or never. Larrey had profited by the surgical experience of the surgeons who had participated in the American Revolution and the different Indian conflicts, who, having no great hospitals to which to send their wounded, performed most of their major operations on the field, and had lost very few men. These observations led him to adopt, as soon as the *ambulance volante* was introduced into the French armies, the practice of immediate amputation in the field. Larrey declares the advantages of this procedure to be great in that shock was considerably lessened, and the cases of tetanus considerably reduced. From the foregoing it can be seen that the trench dressing station of today is really an American institution revived. How much does modern military surgery owe to the medical men who served under Washington, Greene, Putnam, Wayne?

In the dressing of wounds it was his invariable custom, after cleansing away débris and trimming the parts, to apply loose bandages, and to allow them to remain on several days without being disturbed. Once the bandage was secured it was followed up by pouring some cold lotion over it till it became well saturated through and through. The wounds were always kept moist. This mode of treatment resembles, at least to some extent, the tissue lavage methods now in general use in war hospitals.

As a practitioner he was most resourceful in his therapeutic endeavors. His practice in syphilis was beneficial to the patient despite the criticism it engendered on the part of his confrères. Larrey was one of the first to use the mercurial ointment on the soles of the feet and other parts of the body. For this he was violently assailed in some quarters. His knowledge of syphilis was particularly acute, especially as to the effect this disease had on the arterial system.

As a surgeon he was highly practical, but if we view him as a physiologist or philosopher we shall find many false shadows. Let us look at his character as a man, and take that character from one best able to appreciate it, from Napoleon himself. It is well known that Napoleon left to Larrey by his will 100,000 francs, at the same time recording the notable fact that Larrey was the most virtuous man he had ever known. The manners and person of Larrey were endearing and simple. He will stand forever as one of the bright ornaments of French surgery. His place is beside Pasteur and the great Paré. His long and brilliant career in the military service of France entitles him to a niche in that hall of fame consecrated to those whose motto consists of the single word—duty.

820 Baronne Street.

Dehydration of Foods

It would seem that the old fashioned method of drying fruits and vegetables, which became almost obsolete since the rise of the modern canning industry, is again coming into vogue and is being extended to food products not heretofore subjected to this process. Instead of the primitive methods of the household in former days, however, improved, scientific and mechanical methods are being employed and are being adapted not alone to factories, but to the home and the farm, where products over and above present market demands may be dehydrated and placed on the market as required. Considering the large percentage of water in all fruits and vegetable products amenable to dehydration, the saving in bulk and weight is a transportation economy, as well as one of freight costs to the consumer, which is of great importance under present circumstances. As examples of products not heretofore saved as food, in addition to about all the vegetables and fruits raised on the farm, are beet tops, the outer green leaves of the stalks of celery, fruit on the point of becoming overripe, undersized fruits and vegetables which would otherwise waste, and many other products which will suggest themselves to farmers and gardeners. Practical and efficient apparatus have now been devised to dehydrate all such products cheaply and effectively on the farm. One such apparatus, described in the *Scientific American*, consists of a series of trays for containing the fruit or vegetables, one tray superposed on the other. The hot air as the agent of dehydration is applied to the bottom tray and passes upward through all the other trays, not passing off until completely saturated, thus economizing in the matter of heat. The contents of the lower tray become cured first, when this tray may be removed, the remaining trays dropped to occupy this space, and another tray of fresh product added at the top. The process thus becomes a continuous one. In the process of dehydration about 10 per cent. of the water is allowed to remain in the products, which prevents their structural disorganization and preserves their flavors and other natural qualities when cooked. The possibilities of the dehydration process in augmenting and making available large quantities of food heretofore not utilized to the best advantage will be apparent.

Physicians May Testify as to What Is Learned After Treating Patients

(Strafford et ux. vs. Northern Pac. Ry. Co. et al. (Wash.), 164 Pac. R. 71)

The Supreme Court of Washington says that in this personal injury case a physician was asked to describe, and did describe, the nature and extent of an examination he made while the injured plaintiff was a patient in the hospital under his care, but was expressly warned by counsel not to state what he found as the result of his examination, and heeded the admonition. After he had answered counsel's questions he was asked whether he had made two subsequent examinations of the plaintiff and he stated that he had, but not as her physician or surgeon, or for the purpose of treating her, but for the purpose of enabling him to testify as to her condition. As to discoveries made at these two examinations he was ermitted to testify fully. Clearly this was not error. As to o examinations he was as competent to testify as physician or surgeon would be under the same ces. The fact that he had previously treated the id not preclude him from testifying to matters he sequently learned as to her condition under circums not precluding his right to testify. In order to render ysician incompetent, the information he is called on to sclose must have been acquired while he was attending the patient in a professional capacity for the purpose of treating her ailments. The privilege when the examination is made by the physician for the express purpose of publishing the results; such, for example, as testifying in an action for personal injuries. There was therefore no error committed in the admission of the physician's evidence. The same was true of the testimony of another physician who, while he had formerly treated the plaintiff in a professional capacity, testified to no condition the knowledge of which was acquired by him while so treating her. He also subsequently examined her under circumstances similar to those related of the physician first mentioned, and testified to conditions learned at such examination. The statutory rule was not violated in permitting him so to do.

Barring of Action for Roentgen-Ray Burn

(Ogg vs. Robb (Ia.), 162 N. W. R. 217)

The Supreme Court of Iowa affirms a judgment in favor of the defendant that the plaintiff's alleged cause of action was barred by the statute of limitations. The court says it was alleged that in 1901 the plaintiff, then under 17 years of age, broke his right wrist. In July of that year, the defendant called the plaintiff into his office, without the knowledge or consent of the plaintiff's parents, and experimented on him with a Roentgen-ray machine to secure pictures of his hand and wrist. That the defendant continued for ten days in said experiments, and used the Roentgen-ray machine on the plaintiff's hand and wrist many times and made long and close exposures. That as a result the skin on the hand and wrist became discolored. That the defendant then informed the plaintiff and his parents that the use of the Roentgen-ray machine caused such discoloration, and then falsely and fraudulently informed them that this discoloration was of no particular consequence and would be temporary in its effects, fraudulently concealing from them the true effect of radio-exposure produced by the Roentgen-ray machine. That the defendant then treated the discoloration for a time and it apparently disappeared, leaving a scar, but with the usual use of the hand. That the plaintiff and his parents fully relied on the statement and advice of the defendant as to the temporary effect of the Roentgen rays, and nothing further was done in regard thereto until 1912. That the use of said machine by the defendant produced a cancerous condition which was latent until 1912, and the plaintiff had no knowledge of said condition until then. That then the tissues of the right hand where the Roentgen rays had been applied broke down and became an epithelioma or malignant cancerous growth, which caused great pain and necessitated the amputation of the right forearm. Was the plaintiff's cause of action concealed by the statement of the defendant that the original burning was but temporary and was of no particular consequence, and that the defendant fraudulently concealed the true effect produced by the use of the Roentgen-ray machine? The plaintiff alleged that he was burned in 1901 and, as he alleged, by the negligence of the defendant. This fact was known to the plaintiff and his parents. All damages which subsequently developed were traceable to and based on that act. By the original act the plaintiff was injured, and, as the petition alleged, by the negligence of the defendant. He would have been entitled to some damages at that time; and, if it be true that cancer necessarily and in all cases is the result of such burning, or if cancer is the probable result, such fact could be shown as bearing on the question of damages in an action for the original injury. If cancer is not the necessary or probable result of such burning, then the defendant's statement would be more or less of an opinion, and in that case the fact that later and in 1912 a cancerous condition did develop and the plaintiff's damages might thereby be increased, would not constitute a new cause of action. It would seem then that the plaintiff's cause of action accrued at the time of the original injury.

Giving Egg and Toast to Typhoid Fever Patient

(Ennis vs. Banks et al. (Wash.), 164 Pac. R. 58)

The Supreme Court of Washington reverses a judgment for $9,000 damages that was rendered in favor of the plaintiff on the second trial of this case, after this court had reversed a judgment for $1,500 rendered on the first trial. The court says that defendant Banks was called on the 22d to see the plaintiff's son, whom he found suffering with typhoid fever, and who was the next day removed to a hospital conducted by said defendant. From that time until the 14th of the following month the patient was a very sick man. Gas would accumulate, almost constantly, in his stomach and bowels, and, on the 11th, the defendant called into consultation two other physicians. It was then concluded that an operation was necessary, in order to remove the gas, but the plaintiff would not consent to it. The patient had before this been fed on a milk diet, which apparently did not agree with him, and was subsequently fed on beef broth. The latter diet seemed to agree with him better than the milk diet. On the 12th and 13th, the patient seemed to be somewhat improved. On the 14th, the defendant caused to be prepared a slice of bread, about three inches square, from which the crust was removed, and which was toasted and soaked in boiling milk until soft, and on it was placed an egg that had been broken into hot water and allowed to coagulate. The patient ate about two-thirds of the egg and toast. About three hours afterward, an eggnog was given to the patient, who then vomited the eggnog, the egg and toast. The patient at that time seemed to be worse. The plaintiff then had the patient removed to her home, about a block away, and called a homeopathic physician, who treated the patient two days, when he died. Afterward, this action was brought, based on alleged malpractice in feeding the patient the poached egg and toast.

The evidence showed that the patient's death might have been due to one of three causes: first, the disease itself; second, the carrying of the patient from the hospital to another place, and third, the change of diet. Under the rule established when the case was before this court previously, the court is constrained to hold that it was for the jury to determine which of these causes resulted in his death, and whether the defendant, in administering the toast and egg, was guilty of malpractice. But instructions on general negligence, which, in effect, told the jury that, for want of ordinary care generally, the defendant was liable, should not have been given, as the jury were thereby led to believe that they might consider any acts of negligence, or general acts, and make up their verdict outside the issues of the case.

An instruction to the effect that, in determining ordinary skill and diligence, the advanced state of the profession at the time might be considered, was misleading, since there was no evidence in the case that there was any advanced state of the profession at that time. Again, each school of medicine is entitled to practice in its own way, and because one does not use the methods of the other is no reason for holding the one for malpractice. The issue in this case was a simple one. It ought to have been covered in, at most, a half dozen instructions, to the points that unless the jury could say that the patient died solely from the effect of the soft toast and egg which was administered to him, and not from the disease, or from being carried from the hospital, at the stage of the disease he was then in, there could be no recovery of damages; that there could be a recovery only in case the giving of the toast and egg was the prime cause of the patient's death, and the defendant knew, or should have known, such result would follow. Before the plaintiff would be entitled to recover for malpractice, the jury ought to have been told that they must find the defendant did not use his judgment in administering the egg and toast, under the circumstances, but was guilty of malpractice in administering such toast and egg at that time.

17 *To What Extent Have Sun's Rays an Influence in Treatment of Bone and Joint Tuberculosis? A. H. Freiberg, Cincinnati.—p. 625.
18 *Association of Arterial Hypertension and Chronic Arthritis. P. P. Swett, Hartford, Conn.—p. 635.
19 Suspension with Extension in Treatment of Fractures of Limbs. J. Blake, France.—p. 644.
20 *Apophysitis of Os Calcis. A. D. Kurtz, Philadelphia.—p. 659.
21 Osteochondritis Deformans Juvenilis; Report of Case. A. B. Galvin, Springfield.—p. 664.

17. **Sun Rays Treatment of Bone Tuberculosis.**—From an experience with three cases Freiberg concludes that exposure to the sun's rays resulted in speedy improvement, which can fairly be attributed to this agency. The retrogression which ensued on having to abandon the systematic use of the sunlight seems to emphasize this fact, and makes it desirable to continue this during the winter in his own environment. The results obtained by Freiberg seem to indicate the value of this method, even in the vicinity of large cities and at low altitudes, where, according to Rollier, the potency of the ultraviolet rays is greatly diminished by the stratum of moist and unclean air through which they must pass. It is by no means certain that the ultraviolet rays are the essentially active or the only active part of sunlight, in a therapeutic sense. In Freiberg's experience the use of the quartz ultraviolet lamp, the so-called Alpine sun lamp, has failed to show that it may be considered even a fair substitute for sunlight. Its light, on the other hand, is quite rich in ultraviolet rays. It seems worth while to strive to construct a form of shelter for patients which will protect them from unendurable cold and especially humid winds, thus making possible the continuance of treatment during bright days of the whole winter season. It seems necessary to expose the whole body surface in order to obtain the best results. Such shelters should, therefore, have as covers some material permitting the easy passage of the ultraviolet rays. An investigation in this direction is under way, but has not yet yielded any result of value.

18. **Arterial Hypertension and Chronic Arthritis.**—Seventy cases of these combined lesions have been studied sufficiently by Swett to warrant the assertion of a definite diagnosis. The average blood pressure readings of the seventy cases was 182. In thirty-seven, or 52.6 per cent., Heberden's nodes were present. The author is convinced that arterial hypertension and chronic hypertrophic arthritis occur simultaneously in a large number of instances. The effect of treatment directed against the hypertension by means of general régime, or by specific medication, is to improve or arrest the progress of both conditions in the vast majority of the cases.

20. **Apophysitis of Os Calcis.**—Three cases are cited by Kurtz. The condition is one that is caused by an overstrain of the epiphyseal junction some time before complete ossification occurs. The prognosis is good for ultimate recovery, provided the proper treatment is carried out. The indications are rest, until pain has subsided, and then some means should be used to relieve the strain from the heel while it is functioning. This may be met by the use of the rubber pad in the heel of the shoe.

38 Artificial Impaction of Hip; Report of Cases. F. J. Cotton, Boston.—p. 380.

23. Carrel Method of Treating Wounds.—Gibson is of the opinion that, while the Carrel method of treating wounds has not worked any miracles, he has been able to control suppuration more promptly than by any other method, and certainly the results of the bacterial examinations as recorded in his charts show in practically all instances an immediate and constant diminution of the bacteria.

26. Empyema of Thorax.—The 100 patients whose cases Lilienthal tabulates represent thirty-eight minor thoracotomies with 18.4 per cent. mortality; forty-four major thoracotomies, many of them preceded by minor thoracotomy, death rate 27.2 per cent. Resection of ribs with their periosteum and gauze packing in encapsulated empyema treated as if it were an abscess, seven cases with no deaths. Resection and drainage by the old method seven cases with one death, or 16.6 per cent. In all cases there has not been a single thoracoplastic collapse operation. There have been a number of revisions, secondary and even tertiary, but eventually all the patients went home with symmetrical chests and fully expanded lungs.

31. Indications for Cholecystectomy.—Porter says it is neither necessary nor advisable to remove the gallbladder except when it is diseased or injured beyond the probability or possibility of restitution, and that this power of restitution may be presumed to be lost only when one or the other of the following conditions obtains: Hydrops with obliteration of the cystic duct; calcareous degeneration or fibrous degeneration with contraction; chronic empyema; the cholesterin or strawberry gallbladder; carcinoma; extensive laceration or perforation; gangrene other than localized gangrene, such as is sometimes caused by pressure of a stone.

35. Carcinoma of Splenic Flexure of Colon.—The splenic flexure is the third most common site for the growth of colonic cancer. This growth tends to the production of obstruction with indeterminate premonitory symptoms. This complication occurs acutely in nearly three fourths of the cases coming to operation. A recognition of the foregoing facts, and a more careful detailed study, with a possible exploratory operation, should lead to an early diagnosis in a majority of the cases, and thus forestall acute complications. The probable operative mortality of all cases up to the present time is over 60 per cent., and the per centage of prolonged cures is exceedingly low, 10 to 25 per cent. These appalling results are largey due to the delayed diagnosis, and an improper mode of attack. The latter should follow the principle of the two or more stage operation with provision for external colonic drainage, either as a preliminary, or at the time of resection; always the former in the presence of serious obstruction or abscess formation. The distal portion of the transverse colon, the flexure and the entire descending colon must be resected in order to obtain the requisite conditions for a secure anastomosis with an ultimate patency of the colonic lumen.

36. Infections in Prostate Cases.—In prostatic cases, a definite reaction occurs during the preoperative treatment. In some cases this reaction may be due to infection in the kidney. Several days after the beginning of treatment or after the operation has been performed, in a very large majority of cases, the urine shows a considerable number of colon bacilli. Judd does not believe that this can be due to contamination in every instance, although he is unable to say whether it comes from the kidney, the bladder, or the prostate itself. He suggests that the infection may be walled off in the kidney and therefore no organisms will show in the urine. Simultaneously with any form of treatment, the infection becomes active and the urine immediately shows bacteria. Colon bacillus vaccine may modify the infection, though it does not decrease the number of colon bacilli in the urine.

50 Shock at the Front. W. T. Porter, Boston.—p. 326.

48. Bruck's Serochemical Test for Syphilis.—The results of the Bruck serochemical test in 405 cases are presented by Smith and Solomon. In 101 of these cases there were definite clinical manifestations of syphilis, in which the Wassermann and Bruck tests agreed positively in seventy-four, or 75 per cent. The two tests agreed negatively in twelve instances, and were at variance in 15. In the group which showed syphilis of the nervous system there were sixty-four cases of clinically certain general paresis, of which the Wassermann and Bruck tests agreed in fifty-four instances, or practically 85 per cent. In other forms of central nervous system involvement the agreement was 100 per cent. in the fifteen cases tested. In the cases with no apparent involvement of the nervous system the agreement was somewhat less, being 76 per cent. This may be in keeping with the fact that the Wassermann test was not so strongly positive in these cases. The advantages of the test are: (1) the short time required to perform the test; (2) the limited amount of apparatus necessary, and (3) the simplicity of the technic. The disadvantages of the test seem, for the most part, to be bound up in the personal variations that are apt to occur.

49. Paresis or Dementia Praecox?—It seems proper to Gosline to call those cases paresis which show the mental picture and the physical signs of paresis, whether they have the positive signs of syphilitic infection or not, and to call those cases dementia praecox which have the mental and objective signs of dementia praecox, regardless of whether they have a syphilitic infection or not. Only in this way, says the author, can the problem be solved as to why certain paretics recover with more dementia than others, why some are less amenable to treatment than others, and, finally, why some have negative findings for syphilis.

61 Significance of Agglutinins in Immunity of Rabbit to Hog Cholera Bacillus. C. Ten Broeck, Princeton, N. J.—p. 441.

51. **Pulmonary Distomiasis.**—Nakagawa says that the chief causes of pulmonary distomiasis are the eating of raw or insufficiently cooked crabs infected with the cercariae of *Paragonimus westermanni,* and the drinking of river water containing them.

52. **Spirochaeta Icterohemorrhagiae in Body.**—The material examined by Kaneko and Okuda came from necropsies performed on forty-three patients who died at various stages of illness. The distribution of the spirochetes in the various organs of the human body differs according to the degree of development of the immune bodies. The spirochetes disappear first from the liver and suprarenals, but remain for some time in the muscle, prostate, thymus, appendix, testicles, epididymis, etc. In the kidneys they can be found for a long time. Their mode of disappearance would seem to indicate distribution varying with the different stages of the disease. And not alone the general distribution, but the local position of the spirochetes changes with the different stages. In the early stage, they are located mainly extracellularly, in the interstices; in the later stage, owing to the development of the immune bodies, in the blood, in the main intracellularly, and within the kidney tubules.

53. **Carrier of Spirochaeta Icterohemorrhagiae.**—In thirty-four out of ninety-two cases, or 37 per cent., examined by the authors, spirochetes identical with *Spirochaeta icterohemorrhagiae* were present in the kidneys or in the urine, as demonstrated directly by dark-field illumination and indirectly by inoculation. The organisms cannot be demonstrated in the blood and the liver, but in the urine of rats harboring *Spirochaeta icterohemorrhagiae* in the kidneys, they are present without exception. Urine containing spirochetes, even in small amounts (0.1 to 0.2 c.c.), infects guinea-pigs when injected intraperitoneally. In Japan, the rat is undoubtedly a carrier of the causative agent of *Spirochaetosis icterohemorrhagica. Mus decumanus* was found to be a carrier in 40.2 per cent. of 149 cases. *Mus alexandrinus* in 0.8 per cent. of twenty-four cases. On the basis of these findings, the authors conclude that the extermination of rats and field mice is a highly important prophylactic measure against Weil's disease.

57. **Pulmonary Embolism.**—The mechanism by which death is produced by an embolus which blocks only a small part of the pulmonary blood circulation is unknown. Mann's investigation was made for the purpose of determining this unknown factor, a purpose he has not been able to accomplish, as it has been possible to produce death experimentally only by a more or less complete blocking of the pulmonary circulation. Emboli made of paraffin and the animal's own blood were sent into the venous circulation of dogs. Death did not occur until the pulmonary circulation was practically occluded. The results were the same whether the blood pressure of the animal was normal or depressed by ether or disease and whether the procedure was carried out under ether or local anesthesia.

59. **Bacterial Anaphylaxis and Infection.**—An analysis of bacterial anaphylaxis and its relation to the occurrences in the animal body during an infectious disease is being made by Zinsser and Parker. They show that the sensitization of the tissues of guinea-pigs, as indicated by the isolated uterus, required three to five days when passive sensitization was employed, and that in these relations conditions with bacterial sensitization were entirely analogous to those revealed for serum anaphylaxis by Dale and Weil especially. It has become apparent that the sensitized uterus reacted not at all with whole bacteria or whole red cells, or, in other words, that before reaction with sensitized organs could occur an extraction or solution of the bacterial cell must take place. The mechanism of injury in the sensitized animal or in the human being so far along in typhoid that antibodies have begun to develop is in part one in which antigen, derived from the bacilli and brought into solution, or rather suspension, in the blood stream, reacts with antibodies which are from the beginning, or have subsequently become, integral parts of the cell protoplasm, the entire process taking place within the cell. The symptoms which appear as the incubation time ends are largely those due to cellular sensitization which probaby begins before any considerable amount of circulatory antibodies is present. Cure would consist of a gradual checking of growth and final destruction of the bacteria, and the consequent cessation of antigen liberation, but delicate hypersusceptibility would probably persist for some time after cure and immunity have been established. Just what the relation between tissue hypersusceptibility and immunity is remains a problem for further study.

Journal of Urology, Baltimore

65 Primary Nonpapillary Carcinoma of Renal Pelvis; Report of Case and Review of Literature. H. L. Kretschmer, Chicago. —p. 405.
66 Diverticulum of Bladder; Case Reports. J. A. Gardner, Buffalo. —p. 439.

62. **Renal Insufficiency with Urticaria.**—A study of the renal function in six cases of urticaria, four of which were hypersensitive to one or more foreign proteins, showed more or less profound disturbances of the functional activity of the kidney in three instances. In one case the disturbance was limited to a marked albuminuria and cylindruria. In two cases the attacks of urticaria and erythema were accompanied by albuminuria, cylindruria, increase in blood urea, profound depression of the index of urea excretion, decrease in the output of phenolsulphonephthalein and retention of chlorids and water. These observations show that during severe attacks of urticaria and erythema multiforme in the spontaneously sensitive, a much more profound intoxication of the body tissues takes place than can be demonstrated in the usual case of serum disease. Longcope and Rackemann suggest that it is probable that the intoxication causes a general distrubance in protein metabolism as well as an injury to the kidney.

63. **Lymphoid and Cystic Bodies in Urethra.**—In approximately 3,500 cystoscopies within the last three and one-half years, Pelouze has seen fifty-one cases. Of this number, he has studied forty-two cases, of which thirty-seven show reasonably certain evidences of tuberculosis. Five are still being studied for further confirmation of a coexisting tuberculous focus. Nine of these cases were observed only once, and did not return for further study. The most striking points in the entire group of cases are the following: Many were, or had been, in direct daily contact with cases of tuberculosis. Thirty-two had had a more or less recent specific urethritis. Almost all of this latter number were being treated for "chronic urethritis." The urine was usually clear but contained shreds. An associated follicular prostatitis was the rule. Frequency of urination was present in twenty-one cases. Burning pain in the fossa navicularis was present in thirty-five cases, usually only at urination. It was the most common symptom calling attention to the lesions. Burning pain at the vesical neck or in the perineum, either constant or intermittent, was present in nineteen cases.

64. **Median Bars as Found at Necropsy.**—Three hundred necropsy specimens of adult male prostates were examined by Randall. They have shown median obstruction to the vesical outlet in 18 per cent. of fifty-four cases. These have been shown to be either (1) fibrous, 10 per cent., or (3) glandular, 8 per cent. The fibrous type of bar has been subdivided into two varieties according to whether the process has encroached on, or drawn up (1) the urethral, or (2) the vesical surface in its development. They are the result of an inflammatory reaction and but a part of a generalized chronic interstitial prostatitis. The glandular type has been

subdivided into two varieties according to whether the hypertrophic process is confined to (3) the posterior prostatic commissure, inside the prostatic capsule and under the sphincter muscle, in which case a thick, broad bar is formed, or the (4) subcervical glands of Albarran, occurring just under the mucous membrane and within the sphincteric ring. Evidences of chronic inflammatory reaction has been the rule likewise in these glandular hypertrophies.

80. Full Term Ectopic Gestation Retained Eighteen Years.—A woman, aged 46, consulted Peterson for an abdominal tumor which has existed for eighteen years. Five years after marriage there was cessation of menstruation, the usual morning sickness and enlargement of the breasts. There was a gradual increase in the size of the abdomen until at the ninth month she was as large as a woman at term. She felt life at the fifth month but does not remember at what time movement ceased. She thought she was pregnant but never had any labor pains. Shortly after the cessation of menstruation for nine months, she began to flow regularly again. She remained the same size, that is, the size of a woman at term, for two years, then gradually became smaller. For the past six years her abdomen has been of about the same size. During the past year she has not been feeling well and has lost 10 or 15 pounds The tumor rose rather abruptly from the pubes, the highest point being half way between this point and the umbilicus. The growth was symmetrical, smooth, somewhat tender and distinctly fluctuating. It was fixed and apparently quite densely adherent to the parietal peritoneum. Posterior to the cervix could be felt an irregular, tender mass about the size of a small hen's egg apparently attached to the tumor which could be made out as a cystic mass by palpation through the culdesac. It was impossible to palpate the appendages. On cutting through the abdominal wall, the fluctuating sac was found densely adherent to the parietal peritoneum, omentum and portions of the intestine. During the enucleation of the sac the latter was nicked in one portion, giving exit to an oily fluid of about the consistency and color of pea soup. When the sac was cut open it was found to contain the greater portion of a fetal skeleton.

91. Results in Splenectomy.—Gilbert records the blood cell changes, one year after splenectomy in two patients. He found a tremendous bone marrow stimulation immediately after operation, as evidenced by the marked leukocytosis, the increased nuclear red forms and increase in the large mononuclear and transitional groups. One year later he found the differential count very much the same, except for the increase in the lymphocytes and the marked increase in the number of nucleated red cells. The actual number of nuclear particles has remained about the same. One would think, then, that there must be a more essential factor in the blood cell destruction than the spleen. It would seem that the spleen has a very definite relation to bone marrow cell production, and it has a most definite relation to the maturing of the red cells, especially in the destructive metabolism of the nucleus of the red cells. In these two patients who have returned after a definite remission there is now much greater evidence of hemolysis than before. The spleens were removed and both show marked evidence of bone marrow activity with the principal change in the large number of normoblasts with all stages in the formation of nuclear particles.

97. White Operating Room.—The illumination of a room depends on two factors, the amount of light admitted to the room and the amount of light reflected from the surfaces it strikes within the room. After a study of the coefficient of reflection of various colors, H. A. Gardner published his results in the *Journal of the Franklin Institute* for January, 1916, and showed that the coefficient of reflection of white is 88 per cent., of light green 42 per cent., medium green 14 per cent. and dark green 11 per cent. Acting on this principle Secor built an octagon operating room, the ceiling of which was carried to a point, giving the effect of eight triangular panels; four of the sides from tip of pointed ceiling to floor are of heavy ground glass, which admits an abundance of north light. The walls, furniture, etc., are all white; to obviate the effect of the glare they use beaks on their caps, and on bright days large amber-tinted spectacles are worn. The cap used is a modified Mayo cap with small beak, and, to make it cooler, the back part of the skirt is cut away. The beak is made of several thicknesses of muslin with a number of rows of machine stitching and does not in the least hinder sterilization.

136. Huge Dilatation of Esophagus.—The esophageal dilatation in this case was fusiform in shape, the smaller portion of which extended as high up in the neck as the cricoid cartilage. The esophageal sac held as much as 1,750 c.c. of water. The stomach was about normal in size, with a capacity of 750 c.c. The other abdominal organs were normal.

141. Cholecystitis.—One of Hendon's patients was a male, 26 years of age. While at work he was suddenly seized with pain in the region of the gallbladder and went home and sent for his physician. Two days later he was admitted to a hospital. His pain was excruciating; pulse, 120; temperature, 101.6. A tumor was perceptible in the gallbladder region. Incision showed the gallbladder very black and distended; when opened it was found filled with blood clot. There were no stones present. He made a smooth convalescence and died one year later from nephritis.

174 *Neutralization of Virus of Poliomyelitis by Nasal Washings. H. L. Amoss and E. Taylor, Burlington.—p. 189.

174. **Neutralization of Virus of Poliomyelitis by Nasal Washings.**—Tests were made by Amoss and Taylor to determine the effect of concentration of washings on the activity of the virus. Amounts of virus which would certainly produce the infection if injected directly were added to a filtered washing fluid obtained from persons not having been exposed to the infection. The mixtures were separately reduced to small volume in vacuo at low temperatures and injected into monkeys. The results obtained were variable, for reasons which at first were not obvious, but the tests nevertheless showed that the filtered virus in certain amounts may withstand concentration in washing fluids without losing entirely its infective power. The nasopharynx was rinsed with double distilled water and the washings were fractionally sterilized by heating to 60 C. for three successive days. Each person's specimen was handled separately. The virus employed was obtained by filtering a 5 per cent. suspension of glycerolated poliomyelitic monkey spinal cord. To teach 30 c.c. of the washings 7.5 c.c. of the filtered virus were added. The mixture was then incubated at 37 C. for twenty-four hours. Control mixtures of virus and distilled water were subjected to the same incubation. Each cubic centimeter of the mixtures then contained 0.2 c.c. of the filtrate, or at least two minimum lethal doses of the virus. The results of this experiment suggest that the nasal washings of a person suffering from acute poliomyelitis may exercise no restraining influence on an active virus, while those from healthy persons, under identical conditions of preparation, inhibit its activity. The secretions of apparently normal persons vary in the so-called neutralizing power. In each series of experiments the potency of the virus was estabished by control experiments. The secretions of three persons out of six examined varied in their power to neutralize 0.2 c.c. of the virus filtrate at different times under nearly identical conditions, yet the only known clinical differences consisted in the presence of a rhinitis which appears to remove the inactivating power of the secretions.

The neutralizing substance is apparently rendered inactive by heating to 70 C. Apparently inflammatory conditions of the upper air passages tend to remove or diminish the power of neutralization. But irregularities have been noted, even in the absence of these conditions. The neutralizing substance is water soluble and appears not to be inorganic; it appears to be more or less thermolabile, and its action does not depend on the presence of mucin as such. It is suggested that the production of healthy carriers through contamination with the virus of poliomyelitis may be determined by the presence or absence of this inactivating or neutralizing property in the secretions. Whether this effect operates to prevent actual invasion of the virus and production of infection can only be conjectured. The authors suggest that probably the property is merely accessory and not the essential element on which defense against infection rests. It is more probable that other factors exist which help to determine the issue of the delicate adustment between contamination and infection.

1. **Trench Nephritis.**—This paper deals with cases of nephritis in a base hospital, the initial stage being over. The seventy-four cases are placed in four groups: 1. Thirteen cases in which there was either a distinct history of a previous attack of nephritis or definite signs of an affection of the kidneys of some standing. 2. Ten cases in which the nephritis was found to have cleared up on admission, though the symptoms of an attack before admission were quite definite. 3. Nineteen cases which completely recovered in the hospital and were discharged cured. 4. Thirty-two cases which left this hospital not cured, though the majority were greatly improved. The onset in nearly all appears to have been sudden, and edema of the face and limbs, with pains in the back, and dyspnea the chief symptoms; the latter was only partly accounted for by the frequency of bronchitis. Edema at onset was present in fifty-seven out of seventy-four patients. Hematuria, generally slight, occurred in many. The chief symptoms of the disease while in the hospital were edema, most often of the face and limbs, much less often general anasarca; as a general rule, edema showed a disposition to clear up fairly quickly, but in bad cases was persistent, sometimes for many weeks, and in a few attended with ascites and pleural effusion; dyspnea, often but not always associated with some bronchial or pulmonary complication; pains in limbs and back, headache, less frequently vomiting, only occasionally diarrhea, a feeling of great prostration and sometimes mild cyanosis; anemia was only present in the more severe cases and uremic fits in one only.

The average duration before admission to this hospital was two to three weeks, and that of the whole illness until the cases were sufficiently recovered for discharge was, in Group 1, 9.6 weeks; in Group 2 (convalescent on admission), three weeks; in Group 3 (recovered in the hospital), 6.8 weeks, and in Group 4, 8.1 weeks. Of sixty-eight patients, three died, eight were discharged slightly improved as permanently unfit, eleven much improved but the urine contained casts and more than a trace of albumin, six fairly well and able to do light work, and thirty-two recovered completely; of eight patients Clarke has not sufficient information.

The treatment consisted of rest in bed; a fixed diet of 2½ pints of milk, 6 ounces of bread, 1 ounce of rice, ½ ounce of butter, 4 ounces of potatoes, 4 ounces of greens, 1 ounce of jam and fruit occasionally. As improvement took place the bread was increased to 8 ounces and the yolk of one or two eggs was added. Later on, 4 ounces of cooked fish or chicken were added and sometimes more bread and butter. Salt was not used as a condiment, nor added by the cook, except in cooking green vegetables. The amount of water was not restricted when once the kidney began to secrete freely. Many of the patients had only a simple diaphoretic mixture with a saline or other purgative required. Hot air baths were used when free diaphoresis was necessary. Nitroglycerin was given when the blood pressure was raised. Iron was given in the later stages if there was anemia. In many cases with deficient urinary excretion on admission, sodium carbonate was used with very satisfactory results in establishing a free flow of urine.

2. **Reamputation.**—Assuming that a reamputation of a limb has to be done, Chapple suggests early reamputation and the saving of weeks of painful and tedious healing; the control of bony proliferation, the avoidance of spurs, and the protection of the bone end from infection, by careful technic in the treatment of the periosteum; the covering of the end of the bone with muscle fascia and skin in such a way as to (*a*) approach the normal heel as a model and (*b*) provide for the most distant muscle attachments possible; the use of button sutures in every case of primary and secondary amputation in cases in which the flaps are large and the skin is stitched, in order to (*a*) keep severed muscles and tendons as nearly as possible in apposition, (*b*) give immunity from the results of suppuration if it occur, (*c*) prevent hemorrhage between the flaps, (*d*) give the minimum area of flaps and the maximum length of stump in cases in which shortness is a locomotive disability.

3. **Method of Flapless Amputation.**—Handley suggests the trial of a method which, while retaining all the important

advantages of the guillotine method, will obviate the necessity of a secondary operation. It is also, he says, the best way of doing the secondary amputation in cases previously submitted to the Kelly method. In such cases it is necessary (*a*) to remove such a length of bone that an adequate covering of soft tissue is provided for what remains; (*b*) to excise the calcified granulations, which do not afford a suitable bed for the spreading epithelium. If calcified granulated tissues are allowed to remain, it is certain that ultimately the skin will be adherent to the end of the bone; (*c*) to do what is necessary with minimum exposure of fresh raw surfaces, since all these cases are necessarily accompanied by sepsis. Handley makes two punctures at the end of the bone at the outer side of the limb, separated by about one third of its circumference and situated 4 inches above the end of the stump. Through one of them a curved pair of forceps is introduced closed, and is insinuated round the bone until it is able to seize the end of the Gigli saw introduced through the outer puncture. The pair of forceps is then withdrawn, bringing with it the saw. The bone is now divided, care being taken not to rasp the soft tissues. The punctures are made on the side of the limb remote from the main artery so as to avoid all risk of injury to the large vessels by the action of the saw. The end of the bone is now seized by lion forceps and with the aid of a periosteal elevator is easily separated from the soft tissues and removed. Excise the layer of calcified granulated tissue and insert one or two sutures, making ample provision for drainage. In patients exhausted by long continued suppuration it may even be advisable to perform the operation in two stages. The first stage is the subcutaneous division of the bone at the selected level. This operation should run an aseptic course. In a few days the ends of the marrow canal will be sealed by a layer of granulation tissue, and the isolated distal end of the bone can be removed with a minimum risk of osteomyelitis in the proximal end. The method can be used for primary amputations, and Handley has successfully employed it on several occasions.

9 *Subacute Endocarditis plus Pulmonary Endarteritis with Chronic Heart Disease. R. Lutembacher.—p. 353.

9. **Subacute Endocarditis with Chronic Heart Disease.**—Lutembacher gives illustrated descriptions of the necropsy findings in thirteen cases of chronic heart disease. They confirm the assumption that patients with chronic cardiovascular disease do not die from the progress of the disease but succumb to superposed infectious processes, independent of asystolia. The subacute septicemia entails anemia and thrombosis. His patients were all young, without much dilatation of the heart, and compensation had been perfect or had only occasionally briefly lapsed. Suddenly, after some casual infectious sore throat or childbirth they began to exhibit symptoms of infectious disease, slight jaundice and symptoms of embolism in spleen, kidneys or skin. Although the germs are not very virulent and the infectious process keeps subacute, yet its tenacity and fatal outcome render it actually malignant. There is another form of this secondary endocarditis in which the infectious process soon dies out. The outlook is grave only in case embolism develops; otherwise, after infarction in spleen or kidney, all subsides. Lutembacher reiterates that the embolism accident is only the expression of an infectious process; in several of the cases here described the emboli were swarming with microbes, generally streptococci. The clots were found in the right or left cavities of the heart or in the pulmonary artery. One in the left auricle was 5 cm. in diameter and 3 cm. thick. Some were pedunculated. The clinical picture from the clot in the left cavities may prove misleading if the chronic heart affection is not known. The general infection, anemia and rapid pulse suggest paratyphoid or tuberculosis; the renal infarcts may be diagnosed as a tuberculous process in the kidney. Death occurs in from three to nine months unless the infection dies out and after infarction of spleen or kidney, or hemiplegia, the patient throws it off.

10 *Twelve New Cases of Infantile Scurvy. J. Comby.—p. 337.
11 Tubercles in the Pons. A. d'Espine and V. Demole.—p. 355.
12 Case of Subcutaneous Emphysema in Diphtheria. Le Soudier.—p. 360.
13 *Congenital Obliteration of the Bile Ducts. J. Comby.—p. 363.

10. **Infantile Scorbutus.**—This later series brings to forty-one Comby's record of scurvy in infants at Paris during eighteen years. None of the children had been getting breast milk or fresh milk or even simply boiled milk; all had been fed with sterilized flour foods. Signs of rachitis were present in nearly every case. The artificial feeding is responsible for both, he declares, saying that if the milk is sterilized—dead milk—there may be both scurvy and rachitis; if the food is fresh—living milk—the child is exposed to danger of rachitis alone. The diagnosis of scurvy is easy for a physician who has once seen a case, but very difficult otherwise. Cases in this series had been mistakenly diagnosed acute articular rheumatism, infectious polyarthritis, polyneuritis, acute myelitis, infantile paralysis, meningitis, typhoid, osteomyelitis, fracture in a child with rickets, syphilitic osteoperiostitis, osteosarcoma, coxalgia or Pott's disease. All the children easily and rapidly threw off their scorbutus, no matter how old or how severe the course. All that is necessary is to think of the possibility of scorbutus and stop all feeding from cans, returning to fresh milk, raw or merely boiled, giving two or three teaspoonfuls a day of orange or grape juice or lemonade. Children over 18 months old can be given soft mashed potato. Meat juice is not necessary. Every child taking sterilized milk is liable to develop scurvy.

13. **Congenital Obliteration of Bile Ducts.**—Comby summarizes and comments on Holmes' recent article with this title in an American journal, endorsing the latter's views.

Bulletin de l'Académie de Médecine, Paris

August 7, LXXVIII, No. 31, pp. 107-118

14 Technic for Treatment of Arteriovenous Aneurysm in the Neck. (Artériorraphie transjugulaire suivie de capitonnage veineux.) R. le Fort.—p. 108.
15 *Device to Protect the Ears against Shock from Explosions. (Obturateurs d'oreilles à chambre de détente.) L. and M. Verain.—p. 111.
16 *Malaria at Salonica. E. Marchoux.—p. 112.
17 *Continuous Aspiration in Treatment of Purulent Pleurisy. J. S. Dauriac.—p. 115.

15. **Device to Protect the Ear Against the Air Shock of Explosions.**—Verain says that over 600 pairs of these little shock absorber obturators are already in use on the firing line and are proving extremely useful, especially for gunners and artillery men in general. They consist of a hollow celluloid or metal olive about 12 mm. long by 9 or 10 mm. wide, provided with a perforated transverse septum inside or other protecting contrivance. The little obturator fits tight into the outer ear but does not deafen it although absorbing the air shock.

21 A Week at the University of Jena in 1909. R. Cruchet.—p. 180.

18. **Traumatic Periosteoma.**—Rocher describes nine cases in which a bullet or scrap of shell grazed the bone or it was injured by contusion otherwise, and the irritated periosteum developed an exuberant bone growth. In four of the cases

the field was practically aseptic, no infectious process developing. In the others the persistence of a fistula indicated that something was wrong. The probe introduced into the fistula passed through a cavity in the periosteoma and the tip could be felt scraping bare bone. When inaccessible to palpation, the periosteoma was shown up by the Roentgen rays. He advises immediate excision, with care to clear away every trace of fungous tissue which otherwise might keep up the suppuration. An electric head lamp is almost indispensable for these operations. Any scrap of periosteum left may bring recurrence. He completes the operation by swabbing with zinc chlorid.

27 Traumatic Facial Diplegia. R. Oppenheim and G. L. Hallez.—p. 136.
28 Superficial Tension of Royat Mineral Waters. G. Perrin.—p. 139.

25. **Malarial Eruptions.**—De Brun states that his systematic examination of 160 patients with malaria has convinced him that it must be classed with the eruptive diseases. He found the eruption marked in sixty-two of the 160 and it developed later in some of the others. Probably the reason why it has escaped attention hitherto, he remarks, is because the eruption is not of a noticeable tint and it fluctuates. It is generally of a pale pink or light violet color but may sometimes be a bright pink or lilac. It may spread all over the body, sparing only the face, neck, soles and palms. The general aspect is much like that of measles only for the lighter tint and that it never displays the miniature flat papules of measles, and is usually restricted to certain regions, mostly the sides of the chest and thorax. In the milder cases the eruption is represented merely by a few scattered patches, not more than ten or twelve in all, scattered on the flanks, the sides of the chest, the region above the trochanters, the vicinity of the false ribs or the axillary margin of the pectoralis. The erythem disappears under pressure but returns at once, and it is liable to blanch as the region is exposed to the air. The erythem is most pronounced in the morning; bed rest seems to favor its eruption. There was never any subjective symptom from it and he never saw signs of desquamation. The erythem seems to appear and disappear in waves. The momentary complete eclipses are characteristic, as also the final complete disappearance. Probably the patients with negative findings had been examined only during the intermissions of the eruption. No regularity in the development of the waves could be detected; the eruption was noted as well in the febrile as in the afebrile patients, and whatever its intensity, its evolution was always silent. In short, he adds in conclusion, the erythem of malaria occupies a special place in the group of toxidermias.

26. **Eruptions Under Salvarsan.**—Milian noted eruptions of different types in over 3 per cent. of 326 men being treated with salvarsan or neosalvarsan and in over 7 per cent. of 206 women. They were more common possibly with intravenous than with intramuscular injections of the drug. In three more recent cases there was a grave exfoliating erythrodermia and in two others rubeola developed immediately after the injection. He is inclined to accept the idea that the drug has a stimulating action on certain germs, including the unknown germ of rubeola, notwithstanding its destructive action on spirochetes. The phenomenon, he continues, is like mercurial stomatitis. The mercury does not cause the stomatitis directly, but it stimulates germs already present on the gums to start the stomatitis. Boils are liable to develop under salvarsan in those with furunculosis, and lichen planus to flare up anew.

July 26, XXV, No. 42, pp. 433-440

29 *Diagnosis of Tuberculous Otitis. M. Lermoyez.—p. 433.
30 Management of Malaria in Soldiers. Wurtz.—p. 435.
31 Aspect of Stools in Atypical Forms of Amebic Dysentery. C. Mattéi and M. Bloch.—p. 436.
32 Alcohol in Disinfection of the Hands. E. Viguier.—p. 437.

29. **Tuberculous Otorrhea.**—Lermoyez insists that many cases of otitis media are the work of the tubercle bacillus. He found tuberculous otorrhea ten times to every ninety osteomyelitic cases. In 20 per cent. of the tuberculous otorrheas both ears were affected. Fully 75 per cent. of all the cases he has encountered were in children, but among the adults affected there were four times as many men as women. He declares that we must stop looking at such patients through the keyhole and bring them out into the open for examination. A suppurating bone process requires treatment along the same lines whether it is in the ear or hip joint, and exclusion of tuberculosis and syphilis is the first step. The tuberculous nature of the process may be suspected only from the lack of normal healing after a mastoid operation. Even a retrospective diagnosis like this may be important as a guide to further treatment. Other aids in the differential diagnosis are the insidious onset, the paradoxic deafness, the white caries, pale granulations, and the persisting fistula. Microscopic examination of one of the pale granulations may reveal the tuberculous follicle, and inoculation of guinea-pigs is conclusive. He warns against tuberculin tests, as any reaction at the focus to a tuberculin test is liable to have disastrous effects in the ear. It might even bring on facial paralysis, labyrinthitis or meningitis, and hence should be strictly proscribed.

Progrês Mêdical, Paris

July 28, XXXII, No. 30, pp. 249-256

33 *The Oculocardiac Reflex in Bradycardia. A. Mougeot.—p. 249.
34 *Emetin plus Arsenic in Treatment of Amebic Dysentery. H. Aimé.—p. 253.

August 4, No. 31, pp. 257-264

35 *Paroxysmal Stuttering. M. Briant and J. Philippe.—p. 257.
36 Choice of Anesthetic in War Surgery. G. Jeanneney.—p. 261.
37 Invaliding of Soldiers with General Paralysis. J. Crinon.—p. 262.

33. **Significance of the Oculocardiac Reflex in Bradycardia.**—Mougeot's experience with fourteen patients with bradycardia has confirmed the assumption that the persistence of the oculocardiac reflex eliminates true heart block from the diagnosis and proves the nervous origin of the bradycardia. On the other hand, a negative response to the ocular test does not decisively disprove the nervous nature of the trouble. In some of the men suffering from shell shock he has found total sinusal bradycardia with no oculocardiac reaction. He explains the mechanism for this, ascribing it to the anastomoses described by Ramon y Cajal between the posterior root of the trigeminal and the tenth and eleventh pairs.

34. **Combined Emetin and Arsenic Treatment of Amebic Dysentery.**—Aimé reports prompt improvement in eighteen cases of amebic dysentery, that had long resisted other measures, when he instituted combined emetin and atoxyl treatment. The atoxyl was the only form of arsenic available at the time. Three of the men were apparently completely cured and ten others much improved. Even in the five cases listed as failures, the general health showed great benefit.

35. **Stuttering as Symptom of Shell Shock.**—Briand and Philippe comment on the remarkably small number of cases of stuttering brought on or aroused by the emotional stress of the war. In one case the soldier had stuttered from childhood. His speech had been natural until the age of 4 when, after a severe fright, he began to stutter and has had periods of stuttering since, alternating with periods of normal speech. The stuttering came on again in a severe form after shell shock, the features of the case analogous to those with rebellious deafmutism of emotional origin. The course of training which conquered the tendency to stuttering is described in detail. It commenced with breathing exercises, showing the patient the tracings and how he must learn to manage the diaphragm to bring the tracing to normal, training him in exerting the muscles necessary to regulate dia-

phragm functioning. This was accompanied by reading exercises in solitude, slowly reading the words in a low voice to himself, noting the letters that start the stuttering and meeting each one with a deeper, more prolonged respiration. The breathing exercises are done more readily while walking slowly than when seated or reclining. Any overexertion, exhaustion or strong emotion is liable to bring a setback. In the case described the stuttering was conquered in the course of three weeks.

47 *Remission for Nine Days in Case of Fatal Mushroom Poisoning. P. Gautier and C. Saloz.—p. 291.

39. **Auscultation of the Blood Pressure.**—Tchertkoff gives the tabulated findings with Korotkoff's method and with Pachon's oscillometer. He declares that the former is the simplest, the easiest and the least exposed to subjective errors. The findings are as exact as with the oscillometer for the minimal pressure and are more reliable for the maximal. The Riva-Rocci cuff is placed on the arm at the lower third and we listen through a small phonendoscope or stethoscope placed lightly on the humeral artery in the bend of the elbow. As the cuff is inflated we hear nothing, but as the mercury drops we hear four phases of sounds and a phase of silence. These phases are so distinct and significant that this rapid method seems destined to supplant all others. He tabulates the findings in twenty-eight reclining patients, the arm lying along the body, also in eleven reclining with the wrist on a level with the heart, and in ten in which the oscillometer and the Korotkoff were each applied to the humeral artery.

41. **Purpura Affecting the Bladder.**—Perrier's patient was a man of 31. There were other manifestations of the purpura on the skin. The previously healthy man was free from venereal disease and the hematuria had developed after a few days of high fever. In a second case, the young man had no appreciable manifestations of the purpura except in the bladder. When one has once seen the patches of purpura in the bladder it is impossible ever to mistake them again unless possibly for the patches of ecchymosis sometimes found in the bladder with incipient local tuberculosis.

42. **Fastening the Intubation Tube in the Throat.**—Bernasconi expatiates on the great advantages of Polverini's method of holding the tube in place by a thread brought out through the middle of the neck below the chin. There are no blood vessels or nerves in this region to be injured, and the needle passes readily through the aponeurosis, the thyroid membrane and adipose tissue. When it is a question otherwise of tracheotomy, this method of fastening the tube will be found comparatively simple and always reliable. The O'Dwyer tube has two small holes drilled at the front near the usual thread hole. The finger is introduced into the throat as for intubation. An ordinary long and stout needle, carrying a long, strong but not too heavy silk thread, is inserted into the neck exactly on the median line, and is passed through the thyroid membrane at the junction of the middle and lower thirds. With the index finger of the left hand introduced into the throat, as for intubation, the point of the needle is felt as it enters the throat and is guided upward until it can be seized and drawn out of the mouth, with its thread, above, the ends of the thread projecting from the throat below. The upper end is passed through the two holes made for it in the head of the tube and is tied in a double knot, about 50 or 60 cm. below the upper free ends of the thread. The tube is then placed in the throat, and the long lower ends of the thread projecting from the neck are tied over gauze and protected by gauze fastened to the neck with adhesive plaster. The tube can be drawn out to be cleansed by pulling on the upper ends of the thread after untying the lower ends. If the tube has to be worn a long time, Polverini usually cuts off the upper ends of the thread as the child is liable to bite them off and the parts left might slide down and obstruct the tube. In the five cases inspected by Bernasconi, the children had worn their tubes for several months and ate fluid and solid foods as if there was nothing in their throats. As the holes are in the front of the head of the tube, this prevents its twisting around the thread. (This method of ensuring the stability of intubation has already been described in The Journal, Feb. 10, 1917, p. 495.) The results in the twenty cases in which Polverini has applied this method in the last ten years have apparently confirmed its harmlessness while there could never be any question as to its efficiency. Two illustrations show the exact technic.

44. **Mushroom Poisoning.**—Roch relates that there was an unusual number of cases of mushroom poisoning in the Geneva district last fall. He knows of 100 cases, with four deaths, and summarizes the details from the twenty-four families involved. Early and profuse vomiting was what saved many from death, and the physician should strive to ensure this in all cases. When any one shows signs of mushroom poisoning, all who have partaken of the meal should be made to vomit freely, even although they show no symptoms at the time of anything wrong. Aside from this indication, it seems useless to give emetics and purgatives because they do not act until there is nothing left to evacuate. They merely increase and prolong the emetic-cathartic phenomena of the poisoning to no purpose. No benefit seemed to be derived from charcoal, but at least it did no harm. Treatment can be only symptomatic, drinking copiously, injecting saline and giving laudanum, camphor or caffein as indicated. Roch analyzes the clinical picture induced by the different mushrooms. The *Entoloma lividus* was responsible for a number of the poisonings. This mushroom was exceptionally abundant last September. It has a delicate white meat, with a tempting odor, and deceptively resembles some harmless varieties. One or two hours after eating there is sudden uncontrollable vomiting, diarrhea for four or five days, intense thirst, sometimes pupil disturbances and syncopes, the throat intensely dry. The gravity of the accidents with mushroom poisoning is usually in inverse proportion to the length of the incubation. When the vomiting comes on early the attack is usually mild. Roch's article is a comprehensive study of poisoning from the various species of mushrooms.

46. **Treatment of Cicatricial Stenosis of the Esophagus.**—The patient in the severe case described, with illustrations, was a robust man of 42. By persevering retrograde dilatation over several months he is now practically cured. Kummer and Moppert found metallic mercury a great help in this. The mercury does not stick to the walls, and by its weight it settles down on the constricted portion of the esophagus and, by its property of separating into minute globules, its heavy droplets worm their way through the stricture and help dilate it. They say that there need be no fear of poisoning as metallic mercury is not absorbed at all. At first they rinsed it out through the gastrostomy opening, but later allowed it to pass off through the bowel. It took from one to eighteen days for the 10 c.c. to be entirely voided. It never caused any disorder except sometimes a little tension in the abdomen the few hours that preceded its evacuation by the rectum. Another advantage of the mercury was that it cast such a clear shadow that this, besides its mechanical aid, materially facilitated the working of the dilating catheter into the stricture during radioscopy. In conclusion they endorse the suggestion that when a caustic has been swal-

lowed, an esophagus sound should be introduced at once and left permanently until healing is complete. The presence of the sound not only wards off stricture but it allows the patient to be fed from the first.

47. **Mushroom Poisoning.**—The robust man had apparently recovered from the poisoning with the amanita mushroom and had returned home from the hospital. After *nine days* of complete remission, the symptoms returned and proved fatal the thirtieth day after the *mushrooms had* been eaten.

50 Metal-Albumin Preparation for Diagnosis of Pregnancy. III. (*Schwangerschaftsreaktion mit Dia-Sorcym-Placentae.*) K. Kottmann.—p. 1012.

48. ***Problems of Metabolism and Immunity in Dermatology.***—Among the points to which Bloch calls attention is the preeminently important part played by the skin in the phenomena of allergic immunity and sensitization. This is in marked contrast to serum immunity, as in tetanus and diphtheria, in which the blood is the bearer of the defensive forces. The history of our knowledge of immunity, beginning with Jenner's vaccination, has almost invariably made its progress by study of the skin, from Koch's fundamental inoculation of guinea-pigs with tuberculosis to the Pirquet reaction, trichophytosis, syphilis and tuberculosis. *Infectious diseases* which are followed by allergic modifications that confer immunity, and the acute exanthems, scarlet fever, measles, etc., which are likewise distinguished by conferring immunity, all play such an important rôle in the skin that this suggests that the skin has some biologic function not yet fully understood. The skin is open to the external world and is thus exposed to all infections coming from without and it has adapted itself to defensive reactions. This adaptation is acquired, not natural, as is evidenced by the lesser reacting power of the skin of animals and of young infants. By this function of the skin part, at least, of the invading germs are held back and the internal organs spared. He reiterates that the body fluids are not concerned in immunity; it is of tissue origin. He has presented direct proof of this with trichophytosis; a scrap of skin from a person who had had this affection, transplanted into a normal person, conferred allergy on the latter. This seems to be the case also with variola. In discussing the part played by the skin in syphilis, he remarks that salvarsan cures so quickly that the tissues have not had time to develop allergic modifications under the influence of the spirochetes. The consequence is that a new infection from without, or the rousing of some slumbering nest of spirochetes, induces a response in the body the same as if the individual had never been infected with syphilis. We are liable now to encounter patients with a fresh primary lesion, buboes and syphilids, all at once.

49. **Granulation of Malarial Blood Is Due to the Anemia.**—Hirschfeld discusses the layer of granulations which is evident, even to the naked eye, when a smear is taken of malarial blood. The corpuscles seem to pile up at some one point of the smear. He noticed this in several hundreds of patients with acute or chronic malaria, and it was extremely pronounced in malarial coma and blackwater fever. His analysis of the conditions has shown that the red corpuscles drop out of the blood plasma the more readily, the more diluted the blood. Hence the speed with which the blood corpuscles form a sediment, in their own blood plasma, is directly proportional to the degree of the anemia. It is this rapid dropping out of the reds in malarial blood which gives it the granulated aspect. It has nothing to do with the coagulability of the blood nor with agglutination phenomena. As soon as the number of corpuscles falls below a certain ratio to the blood plasma, then this rapid dropping down of the reds is liable to occur. In other words, it is a phenomenon of hypoglobulia. By adding plain plasma to any blood a point is reached at which the reds drop to the bottom. It is a sign of anemia, he emphasizes, but he has had no chance to study it on any but malarial subjects. In physiologic salt solution the reds are in a condition of suspension balance, and they do not drop down. In normal blood the corpuscles are so close together that the elasticity of the others prevents the sinking to the bottom of a corpuscle that has started to fall. In anemic blood this hindrance to sedimentation is lacking, the corpuscles being so few and far apart.

July 8, XXXVIII, No. 54, pp. 761-776

51 *Auscultation through the Mouth. G. A. Notari.—p. 767.

51. **Auscultation Through the Mouth.**—Notari describes a puzzling case in which by auscultating the percussion sounds through the mouth an exact differential diagnosis was possible. This oral auscultation has been introduced mainly by Cardarelli, Galvagni, Frugoni and other Italians. It throws light on certain respiratory and heart disturbances otherwise inexplicable. In the present case, the tracings show intermittent respiratory functioning not synchronous with the heart action. In all the other cases published the heart was evidently responsible for the respiratory intermittent functioning, but in this case the diaphragm seemed to be exclusively responsible. Oscillatory vibration of the diaphragm was manifest on oral auscultation, a respiratory neurosis, in an otherwise clinically normal soldier.

52. **Vitiligo with Inherited Syphilis.**—The Wassermann reaction was negative in one of the two cases reported, and was not tested in the other, but the diagnosis of inherited syphilis was beyond question in both. The father of one had progressive paralysis and the daughter, a woman now 30, showed signs of incipient tabes besides the vitiligo and tendency to hysteria. The skin affection had been manifest for fifteen years in this case and for ten in the other patient, a man of 41. There was nothing to suggest tuberculosis in either case.

66 The Inventor of the Immersion Objective for Microscopes. G. B. Amici, 1786-1863. A. Ferrannini.—p. 803.

63. **Syphilis in the Army.**—Moscati emphasizes the necessity for seeking out every syphilitic in the army and ensuring him thorough treatment year after year. According to the system in vogue, men on the firing line with early syphilis are treated there and a course in the hospital is not considered necessary at this stage. The consequence is that the men conceal their syphilis. Rheumatoid pains, etc., are reported to the physician and the men are sent to the home zone hospitals for treatment of "rheumatism." Moscati has found a large proportion of the rheumatism cases to be syphilis alone or associated with rheumatism. The percentage of cases of syphilis during peace times is out of proportion to

the number of cases of declared syphilis now in military circles. Some new factor has intervened and this, he thinks, is either the disinclination to confess venereal disease or ignorance of its existence. It is undoubtedly a fact that ignored syphilis is responsible for the nonhealing of wounds in certain cases.

64. **Gas Phlegmon and Gas Gangrene.**—Nacciarone reports in detail about twenty cases to emphasize the advantages of the technic advocated. When applied within the first six hours he counts on 90 per cent. of cures even when the gas gangrene had developed into a vast lesion. When the bone lesion was limited or only the soft parts were involved and not over twelve hours had elapsed he was able to cure 88 per cent. of the patients without mutilations. In those in which twenty-four hours had elapsed, he cured 85 per cent., including 4 per cent. requiring mutilating operations. In 82 per cent. the complete functional use of the limb was restored. He warns that treatment of wounds with balsam of Peru cuts off the oxygen and thus favors the development of anaerobic germs. Whatever the state of the infection, he begins by degreasing with benzin, then drying and dabbing with 10 per cent. tincture of iodin, swabbing the whole limb with this. Then he incises the limb lengthwise, making as many long incisions parallel to the axis of the limb as are necessary to open up all the muscles involved and open the bone to the air. The first incision is carried through the hole made by the projectile. For the leg he makes at least three incisions, one each in the front, rear and side. There must be ample access to inspect the spaces between each muscle. After the skin is incised, he separates the muscles and fascia with the fingers, refraining from injuring the vital connections between muscles and vessels, but making way for copious irrigation of all the interspaces between muscles and aponeuroses, not leaving even the remotest crevice unopened up. He uses up in ten minutes as much as 20 liters of the iodin antiseptic solution. He has even used 40 liters in some cases, sponging it into every crevice with gauze held with forceps. When no more gas can be forced out by pressure on the tissues and there is no further odor in the depths, he delimits the part involved with the actual cautery to form a wall against further extension, or makes a ring of subcutaneous injections of a 2 per cent. iodized solution. Three or four drain tubes are then introduced at the best points for effectual drainage, draining besides with gauze, after flushing again with the iodin solution. The gas process generally extends upward. This treatment is repeated from one to three times in the twenty-four hours, clearing out any necrotic tissues found. The fetid odor usually lasts for three or four dressings. When suppuration sets in, the patient may be regarded as out of danger from the gas infection. In addition to these local measures, which he describes with minute detail, he combats the general intoxication by saline infusion (for which he uses a special formula) and stimulates the organic defences by giving a little quinin twice a day, with camphorated oil, a little brandy and tepid black coffee. His experience with iodin, he declares, speaks for itself, the men with severe gas gangrene returning to their posts, with complete functional use of their limb, in thirty or forty days. His formula for the antiseptic fluid with which he combats the gas infection is as follows: iodin, 1 gm.; sodium iodid, 1 gm.; sodium chlorid, 3 gm.; sodium carbonate, 2 gm., with water to 1,000 gm. It is not necessary to boil the water, he says, these ingredients rapidly sterilizing it. He finds it convenient to keep a mother solution constantly on hand consisting of 25 gm. each of iodin and sodium iodid; 75 gm. sodium chlorid, and 50 gm. sodium carbonate, with 1,000 gm. water. From 40 to 120 c.c. of this mixture are added to each liter of the water ready to use.

71 Infectious Hemorrhagic Purpura with Initial Abdominal Symptoms in Soldier. L. Tomasetti and A. Costa.—p. 303.

68. **Chronic Hemorrhagic Purpura.**—Schupfer reports in detail with necropsy a case of this kind in a woman of 29 who was under observation for fourteen years, and compares this case with twenty-six others encountered during the same period. He is convinced that it is more than a coincidence that tuberculosis was evident in a large proportion of the cases and in two there was an unmistakable hereditary burden, so that 55.54 per cent. of the total twenty-seven were plainly tuberculous. The necropsy of the case described in detail showed tuberculous cavities in the left lung with numerous tubercle bacilli. The right suprarenal was intact but the left was much enlarged and the seat of tuberculous disease. The woman had had fifteen severe recurrences of the purpura in the course of ten years. No tendency to hemophilia was discoverable in the family. The first attack subsided under ergot, epinephrin, iron and sodium salicylate. There was no further trouble for nearly a year. Then the febrile purpura returned with enlargement of the spleen, but subsided under injections of normal horse serum, calcium chlorid by the mouth and gelatin in enemas. Schupfer reviews the literature on the subject of chronic purpura, and claims that the tubercle bacillus is indirectly responsible in certain cases, and the endocrine system is probably involved in all.

70. **Camp Infectious Jaundice.**—Civalleri regards the jaundice in question as undoubtedly the same disease as that described by Japanese authors as spirochetosis, but he was unable to transmit the disease from man to guinea-pigs except in one instance, while the transmission from man to man was common. Transmission from guinea-pig to guinea-pig was unfailing, using the urine. The bile also gave positive results as it swarmed with the spirochetes. Transmission from one guinea-pig to others was also demonstrated by means of contaminated food.

75 Epidemic Poliomyelitis with Cephaloplegia for Ten Days in Year Old Child. Recovery. R. Moreira.—p. 244.

72. **Circular Heart Murmur.**—De Mesquita refers to the murmur with circular propagation to which attention was called a while ago by Miguel Couto, the leading internist of Brazil. He had noticed it only with mitral insufficiency. De Mesquita reports two cases which show that it may be encountered both during and without asystoly. His further experience has demonstrated that neither mitral relative insufficiency nor passive congestion of the lungs has anything to do with its production. In a typical case described, the girl had had acute rheumatism a year before. The heart was somewhat enlarged and the murmur was holosystolic. It was heard starting at the apex and running around the thorax in a circle, heard in the left axilla, the interscapular region, and the right axilla, and it was still perceptible in the front right half of the chest. De Mesquita discusses the mechanism of its production. Its disappearance seems to be a favorable omen.

78 Factitious Affections. G. F. Davila.—p. 287. Conclusion.

79 Regulation of Prostitution. Committee Report.—p. 306.

76. **Present Status of Our Knowledge of Cholesterol.**—Castañeda describes the present assumptions as to the production of cholesterol in the body and its elimination, mentioning the various tests for it in vogue. The significance of the cholesterol content of the blood in different conditions is also discussed.

77. **Alcoholic Polyneuritis.**—Odriozola analyzes a case in a syphilitic in which the rapid onset of the symptoms of polyneuritis seemed to exclude tabes and the absence of sphincter trouble excluded diffuse myelitis. With syphilitic paralysis there is contracture, while in this case the paralysis was of the flaccid type. The known abuse of alcohol suggested a toxic origin for the pains and paraplegia. The prognosis of alcoholic polyneuritis is favorable, as a rule, but he has had two cases in which fatal bulbar symptoms became superposed, the clinical picture deceptively simulating Landry's ascending paralysis. In treatment, besides massage of the groups of muscles involved and reeducation of movements, systematic galvanization of all the muscles involved and strychnin are liable to give great relief and improvement. Atrophy of the muscles comes on early but the above measures properly applied arrest it almost without fail. Practically complete recovery depends only on the perseverance and skill with which the above measures are applied.

82 *Enrichment of Tubercle Bacilli in Sputum. L. Ymaz.—p. 79.
83 *Echinococcus Cyst in the Liver Perforating into Pleura. C. I. Allende and N. D. Rosso.—p. 80.

82. **Enrichment of Bacilli in Sputum.**—Ymaz first treats the sputum with a 50 per cent. antiformin solution in an amount equal to or only a little less than that of the sputum. It is possible to use instead ordinary Javel water or sodium hydrate. This does not seem to affect the shape or staining properties of the bacilli. Boiling the mixture is a help. He then adds to the homogeneized sputum an equal amount of syrup (*jarabe*) with specific gravity of 1.260. A small amount of ether is added and well mixed, to form an emulsion, but not agitating with the receptacle closed. Then, after lively centrifugation the bacilli will be found in the whitish zone that forms at the plane separating the two fluids. The ether aids in bringing the bacilli to the surface. He says this technic is an efficient method for enrichment while it does away with the necessity for estimating the specific gravity.

83. **Echinococcus Cyst of the Liver Perforating Into the Pleura.**—An operation for supposed purulent pleurisy was done on a married woman of 43, and the pleura was found to contain pus and numbers of daughter cysts, some empty and others intact. The cavity was drained with a large rubber drain but the temperature persisted high and dulness at the seventh rib confirmed the assumption of an echinococcus cyst in the upper part of the liver. This was drained from below the diaphragm through a second incision, suturing the lips of the cyst to the skin. Bile came away with pus but the condition rapidly improved. The retrospective diagnosis was that the cyst had perforated first into a bronchus, the symptoms and expectoration at the time having been ascribed to an acute bronchial affection. A few weeks later the cyst perforated into the pleural cavity, the bronchial outlet evidently having proved insufficient. The ample drainage at the lowest point at both operations conquered the disease. While the cyst was being rinsed out with hydrogen dioxid, some of it got into the bronchi through the primary perforation and poured out through the mouth, causing cyanosis and asphyxia from the foam filling the air passages on that side. The blood pressure dropped rapidly and the condition seemed alarming at first, but the suffocation was gradually overcome. The patient had become unconscious but under stimulants to the heart and inhalation of oxygen she very slowly revived, the blood pressure slowly returning to normal. The next morning there was much mental confusion and dysphasia, with a suggestion of total right hemiplegia. The motor phenomena subsided during the day but the confusion persisted and did not finally disappear until the fourth day. Recovery then was soon practically complete.

93 History of Bubonic Plague. A. M. del Pont.—p. 1115. Continuation.
94 *Best Mode of Access to the Space below the Diaphragm. L. Merola.—p. 1164.

84. **Tuberculosis and Paroxysmal Thyroid Insufficiency.**—Albina's patient was a girl of 14 who had been menstruating for eight months. Each menstrual period was preceded by a day of subfebrile temperature, sweating and persisting pains in some of the joints. They swelled and were tender but there was no edema in the region nor atrophy of muscle tissue. All these disturbances subsided with the menses; during the intervals there was no pain or fever. The findings at one apex were suspicious of tuberculosis, and the general aspect suggested defective thyroid functioning. The lack of any benefit from the salicylates suggested that the joint troubles were of toxic origin. The diagnosis of rheumatism from thyroid insufficiency on a tuberculous soil was sustained by treatment on this assumption. Under thyroid treatment the menses returned to normal, without joint disturbances and without fever. The thyroid treatment was then stopped and treatment for incipient tuberculosis was pushed. After ten months of this the patient was restored to clinical health, with no return of pains or fever after the first month. He began treatment by giving sodium bicarbonate freely for three days and then thyroid treatment for three weeks in increasing doses.

88. **Anaplastic Operations.**—Gamboa gives an illustrated description of a number of particularly interesting cases treated by restorative surgical measures. One boy of 11 who had had a large angiosarcoma of the cheek removed showed five years later very little trace of the extensive operation. The defect had been covered with a pedunculated flap from the neck. The other anaplastic operations were to correct contracture or growing together of parts after burns. The left arm of one child of 11 had grown to her side. The principle which Gamboa specially emphasizes is that the scar tissue should all be cut away and discarded, and only normal skin, with its adipose tissue should be used for flaps to repair the defects. When there is flexion from contracture the whole contracting tissue should be cut away and the resulting defect patched with normal tissue. The parts must be kept in extension until the flaps have grown into place. When the plastic operation is on the fingers he advises a single large flap taken from the abdomen. When it has healed in place another operation is necessary to separate the fingers. This gave perfect functional results in his experience.

89. **Chronic Appendicitis and Ovaritis.**—Gomez declares that chronic appendicitis is habitually accompanied by sclerocystic degeneration of the ovaries. The symptoms from the latter should not be overlooked in studying a case of chronic appendicitis. If the cysts are small and few, it suffices to obliterate them with ignipunctures, but if they are large and numerous, or if there are blood cysts or degeneration of the corpora lutea, a wedge including the lesions should be cut out, and the uterus straightened by ligamentopexy if there

is displacement. If the lesions are bilateral or only in the left ovary or there are still other lesions to be attacked, a median laparotomy is required.

90. **Hypercholesterolemia and Menstruation.**—Goñalons' curves show a marked rise in the cholesterol content of the blood during the menses. In some cases the increase was marked also during the days just preceding. He analyzed twenty-seven complete menstrual cycles, recording the cholesterol content of the blood daily for thirty days and in some cases for two or three months. The blood was drawn from the fold of the elbow; the women were all healthy or convalescent.

91. **Coagulation Index of the Blood**.—Hitce and Iribarne prevented coagulation of the blood by adding 0.0004 gm. sodium citrate to the 0.04 c.c. of blood in each of six test tubes. Then they restored the coagulating property to the blood by reactivating with progressive amounts of calcium. The amounts used in his tests were, respectively, 0 gm.; 0.0001; 0.0002; 0.0003; 0.0004 and 0.0008 gm. In addition to the coagulating power, he tested the resisting power of the red corpuscles, using a 7 per thousand salt solution in amounts of 4 c.c.; 3.8; 3.6; 3.4; 3.2 and 3 c.c. This supplied an index of coagulation for the individual blood. Discovery of an excessive tendency to coagulation suggests measures to ward off embolism. On the other hand, low coagulating power may give the clue to unsuspected liver disease.

92. **Cicatricial Atresia of the Nose.**—The atresia was the consequence of smallpox lesions. Jorge corrected it by making a horizontal incision just below the nose and suturing to the lower lip of the incision the edge of a square pedunculated flap from the upper arm fastened across the face. The raw side of the flap was turned upward, and the plastic operation when concluded proved very satisfactory, the patient now breathing freely through her nose, and with scarcely a trace of the incision below.

94. **Access to Space Below the Diaphragm.**—Merola lauds the advantages of a slanting incision with resection of the rib. The incision runs from the scapular line downward and inward, following at first the ninth rib. The operation is transpleuro-abdominal and requires a U-shaped suture. This incision is the best mode of access also to the cardia and lower esophagus, as he shows by illustrations taken from the cadaver. For this, the incision is supplemented by a vertical incision beginning at the upper end of the first. This allows a triangular flap to be turned back and after resection of the tenth rib and of part of the eleventh and twelfth, the organs below are exposed. The important field thus opened up is amazingly extensive and access to the deep lying organs rendered simple and easy. The suprarenals are under one's hand, as also the posterior aspect of the liver, etc.

Semana Medica, Buenos Aires

June 28, XXIV, No. 26, pp. 767-810

95 Hemorrhoids. J. M. Jorge, Jr.—p. 767.
96 *Lymphocytosis in Syphilitics. C. P. Mayer and A. C. Gourdy.—p. 779. Conclusion.

96. **Lymphocytosis in Syphilitics.**—This is the conclusion of this extensive communication which has been appearing weekly in the *Semana* nearly all the year. The present installment brings to 502 the number of cases of syphilis tested for lymphocytosis, the data in each case being given with the differential blood count on different occasions. Mayer and Gourdy regard the lymphocytosis as the most constant sign of syphilitic infection saying that it appears with the infection and persists throughout life. With inherited syphilis it does not appear until after infancy. Superposed infectious processes may mask the syphilitic lymphocytosis, but as they subside the latter reappears. It is an earlier phenomenon than the Wassermann reaction, and persists after the latter has disappeared. The lymphocytosis is reactivated by specific treatment although not directly, as the latter does not induce lymphocytosis in nonsyphilitics. They are convinced that the lymphocytosis is a biologic reaction which indicates persistence of the causal spirochetes. Also that this alone justifies the diagnosis of syphilis even when no other signs or symptoms of it are apparent. It may be the only sign of syphilis in the wife or husband of a syphilitic, and lymphocytosis in a wet nurse should always be regarded with suspicion. In conclusion they reiterate that the lymphocytosis persists as an indelible sign of syphilis, and that this persistence indicates that treatment for the syphilis should be kept up interminably. The lymphocyte count is therefore the indispensable complement of the Wassermann test in diagnosis and in estimation of the prognosis. Specific treatment modifies the lymphocytosis but never abolishes it entirely.

98. **Hematuria with Kidney Stone.**—Martin remarks that nephrolithiasis should be suspected when the urine shows blood after exercise but only a small amount and only transiently. In three of the four personal cases reported this transient hematuria was the only symptom to call attention to the stone in the kidney. In the other case there was pain in both kidneys and occasional hematuria. The cystoscopic findings in the bladder were normal but one kidney was very large, tender and knobby, and the diagnosis of sarcoma was confirmed by other findings.

102. **Treatment of "Pretuberculosis" in Children.**—Blumenau is convinced that certain subjective symptoms are the work of tubercle bacilli before they have started manifest tuberculosis. This is particularly evident in children, and he recommends for it tuberculin treatment by the inunction technic. He reports experiments on guinea-pigs which apparently confirm that toxins rubbed into the intact skin, after it has been shaved and cleared of grease with ether, pass through the skin as through a special filter, and induce the production of antibodies in the organism. The animals kept well and even increased in weight although they were being given inunctions of diphtheria toxin, given by Moro's technic in a 50 per cent. ointment, rubbed into scarifications, and they survived then the subcutaneous injection of four times the fatal dose of diphtheria toxin. His experiments on animals were not numerous, but the results were so convincing that he applied the method at once to seventy children. The technic he found most effectual was to apply a drop of pure tuberculin to the forearm and then shave off a scrap of skin through it. The mixture of the superficial layer of the epidermis and the tuberculin formed a thin salve, like lanolin, and this mixture on the back of the razor was then rubbed into the skin until dry. A scrap of sticking plaster was then applied over the spot. When removed twenty-four or forty-eight hours later the skin underneath may display a strong, moderate or weak reaction, and the inunction is repeated after an interval corresponding to the strength of the reaction. The dose of tuberculin is also progressively increased to a total of four drops. At first the intervals are usually three or five days, but when the four drop dose is reached, the intervals are a week. The results in the cases of well defined tuberculosis, especially of the lungs, were what might be expected as these types are scarcely amenable to treatment. But in incipient or occult tuberculosis the therapeutic results were prompt and striking.

He gives a brief summary of eighteen cases of various types. Some of the children were only 9 or 10 months old but the majority were between 2 and 13. One child of 13, for example, had been having for six weeks pains in the chest, head and side, coughed a little, sweated freely at night and felt chilly. The appetite was poor and the child was growing thin. There was dulness over the right apex and the temperature wavered between 36.9 and 38.3 C. The tuberculin inunctions were given for a month, a total of ten inunctions. The reaction was pronounced at first but gradually grew less and less distinct while the improvement was marked in every respect. There were no further pains except occasionally in the left side at night when the child lay on that side. The cough disappeared, the appetite returned and the temperature keeps within the normal range, while the child has increased in weight. One 9 months babe had long been coughing and there was a discharge from the ears and from a fistula in suppurating cervical glands, with diffuse dry râles in the lungs. In the course of three and a half months the child had been given twelve inunctions and had increased in weight from 9,000 to 9,500 gm., the cough had ceased, and there was no further discharge from the ears or fistula. The râles had also disappeared.

The parents of children brought to the dispensary often call attention to the child's lassitude, apathy and drowsiness or the reverse, excessive nervousness and irritability, with loss of appetite, restless sleep, frequent and persistent headache, palpitations, cough, pains in the side or chest and in the bones of the arms or legs. The majority of such children are frail, and badly nourished but not all present anemia. The diagnosis of "school anemia" should not be accepted until all other causes have been excluded. It is not enough to examine the child himself; inquiry must be made as to the health of the parents and other relatives, whether any of them have had pleurisy or lingering lung trouble, or any children have died from meningitis, and whether there is any one in the building that coughs much. None of the subjective symptoms are pathognomonic of tuberculosis, of course, but when a possible source of infection is known, the tuberculin test will reveal in many instances that they are the work of chronic self-intoxication.

110 *Alimentary Gastro-Enteritis and Xerophthalmia in Infants. S. Monrad.—p. 1177.

107. **Roentgenotherapy of Sarcoma.**—Nordentoft makes a practice of reporting once or twice a year on the present status of patients to whom he has given a course of treatment with the Roentgen rays at some time for malignant disease. He lists them alphabetically by arbitrary letters, the first series being Aa, Bb, etc., the third, Ca, Cb, etc. He here describes the outcome in eleven cases of sarcoma. One farmer of 37 had had one testicle removed on account of sarcoma. Within a few months there were signs of extension of the tumor into the abdomen, with great emaciation, anemia and pains requiring morphin constantly.. Under a month of rœntgenotherapy the pains disappeared, weight, appetite and sleep became normal and the hard tumor deep in the abdomen could no longer be palpated. Now, four months later, his earning capacity is fully restored. The pains subsided by the next day after the first exposure. Apparently complete recovery is also evident in two other men of 25 and 71 with sarcoma in the pelvis. A third succumbed later to infarction of the lung and recurrence of the tumor. One man of 60 with a large ulcerating sarcoma on the buttocks, of eight months' standing, by the fifth week after the first exposure had merely a depressed cicatrix left as the relics of his malignant disease. Another man of 70 had a tumor in the neck encroaching on the median line and causing suffocation. It had been growing for four months. Under a single exposure it subsided like dew before the sun. Six months later there was a fatal recurrence in the mediastinum. A similar sarcoma in the neck and mediastinum of a man of 64 did not seem to be influenced by the exposures and the patient succumbed, but the improvement was pronounced in a third case, the large tumor visible in the roentgenogram finally disappearing almost completely. A clinical cure was also realized in a case of sarcoma of the small pelvis in an unmarried woman. There has been no recurrence in one case of melanosarcoma of the iris and orbit treated by Roentgen exposures after the operation, but in several similar cases the patients died within a few months from heart failure or diffuse metastasis.

108. **Widening the Indications for Roentgenotherapy.**—Supplementary to the above communication, Nordentoft describes excellent results from roentgenotherapy in a case of acromegaly, the subjective disturbances subsiding and earning capacity being regained, although the acromegalic changes were stationary. Also in a case of polycythemia, the much enlarged liver and spleen subsiding to normal size, although the blood picture showed no change. Also in a case of retroperitoneal tuberculous glands after a number of glands had been removed by a laparotomy. Great improvement followed the exposures also in a case of hypertrophied prostate with retention. Even those writers who do not admit that the prostate is sensitive to the Roentgen rays, recognize that they may have a favorable action on the irritative and nervous symptoms with hypertrophied prostate. Their action here parallels that of Roentgen exposures in case of pylorospasm and hypersecretion with gastric ulcer. Nordentoft emphasizes that roentgenotherapy in the early stages of prostate trouble might prevent the development of the hypertrophy, adding that it would be interesting to investigate whether hypertrophy of the prostate occurs among men working on or with Roentgen apparatus.

110. **Alimentary Gastro-Enteritis and Xerophthalmia in Infants.**—Monrad does not agree with Bloch's statements summarized in abstracts in The Journal, May 12 and 19, 1917, pp. 1444 and 1516), in regard to disturbances in infants from too exclusive carbohydrate feeding or fat deficiency. Monrad has examined the recent records of his service and has found that 205 infants with fat dyspepsia were kept on fat-poor diet for over two months without any symptoms developing suggesting injury from fat deficiency. His experiments and experiences apparently indicate that it is immaterial whether an infant is getting 0.75 or 0.5 or 0.1 per cent. of fat if it is getting the suitable amount of carbohydrates. He protests against Bloch's assumptions as to xerophthalmia being a fat deficiency affection, saying that it is not fat deficiency but pasteurization of the milk which entails the xerosis. Five infants with severe fat dyspepsia and complicating pyuria, otitis or pyodermia, kept on fat-poor food, did not thrive but lay with eyes closed and it was found that all had xerosis of the conjunctiva. Until a few months before this the children in his service had been given raw milk, but a change of owners at the dairy was followed by pasteurization of all the milk. These infants had thus been fed with sterilized milk mixtures, a denatured food, lacking in vitamins, and the conditions were thus propitious for the development of xerosis. Proof of this assumption was obtained by keeping the children on the same food as before but preceding each feeding with 10 gm. of raw fresh milk. The result was the prompt subsidence of the xerosis. It had entirely disappeared by the end of a few weeks. This experience, he thinks, establishes beyond question that it could not have been the small amount of fat in the fresh milk given, but the vitamin content which was responsible for the subsidence of the xerosis. Xerophthalmia must thus be regarded as a consequence of lack of vitamins.

COOPERATION BETWEEN PHARMACOLOGY AND THERAPEUTICS *

ALBION WALTER HEWLETT, M.D.
SAN FRANCISCO

It is important that a healthy cooperation should exist between those who are engaged in the scientific study of drug action and those who use drugs for the purpose of curing or alleviating disease; for the problems of pharmacology, like those of pathology, have a very immediate bearing on medical practice. Established modes of treatment frequently form the starting point of scientific studies, and the exact knowledge thus gained leads in turn to greater precision in treatment. Pharmacologic studies have uncovered new therapeutic possibilities that have ultimately proved useful in the clinic. Finally, a clear recognition of the fact that substances of similar chemical structure frequently possess pharmacologic properties that are similar but not identical has opened up a vast field of research. Numerous compounds of a given type are now produced with comparative ease by the organic chemist. While many or most of these may possess no great practical advantage over their original prototypes, yet such studies are constantly leading to improvements in our remedies, and the possibility is always present that the systematic combination of chemical and pharmacologic research will tap important fields that have hardly been suspected hitherto.

Now more than ever before, therapeutic advance depends on an intelligent utilization of the methods, the criticisms and the new discoveries of pharmacology. Older remedies are being restudied, and from the host of newer ones that are constantly being placed before the profession an intelligent choice must be made. Before I undertake to discuss how cooperation between the pharmacologist and therapeutist may be promoted, however, it may be well to point out some of the factors which tend to separate these two classes of workers. In the first place, their attitudes toward their respective problems are essentially different. The pharmacologist contemplates with scientific skepticism that which is unproved, and he proceeds slowly and carefully from the known to the unknown. The therapeutist, on the other hand, brought face to face with a crisis in the life of his patient, cannot refuse to try the unproved when remedies of known efficacy are lacking. Hence he often grasps at straws, being restrained only by the possibility of doing harm to his patient. Such a practice, justifiable in itself, too often leads to those habits of inaccurate reasoning that are reflected in therapeutic literature. Optimism in practice often means an unjustified and uncritical enthusiasm in the interpretation of results.

The pharmacologist and the therapeutist are further separated by the conditions under which their observations are commonly made. In the laboratory the action of drugs is usually studied on normal animals, and toxic doses can be administered with impunity. In the clinic, on the other hand, therapeutic doses alone are used, and the effects of these are often modified by disease. The pharmacologist is permitted to employ methods of study which involve operative or other harmful procedures. The clinician is restricted to those methods of study that can be used without harm to his patient. Finally, the laboratory worker plans a series of experiments, and he endeavors to eliminate errors by repetition and by controlling the various factors that might influence his results. In therapeutics the number of observations is necessarily limited by the available clinical material, and the interpretation of results is often hampered by the fact that the effect of other factors, such as the natural course of the disease and the action of the other drugs used, is difficult to estimate and is, indeed, often estimated incorrectly. Under such conditions, years may elapse before even a simple therapeutic problem is conclusively answered.

As I have said, pharmacologic studies are usually made on normal animals. In seeking to utilize the knowledge thus obtained for therapeutic purposes, the following questions arise: 1. Are the effects observed produced by doses that can safely and easily be administered to patients? 2. Will the human organism react in the same manner as the animal studied? 3. How is this reaction modified by disease?

The question of dosage, simple as it may seem, has caused and will probably continue to cause occasional therapeutic stumbles. The fact that large doses of strychnin were known to produce a marked rise of arterial pressure in animal experiments was in part responsible for its extensive use by clinicians in conditions of low pressure. Yet it now seems established that in safe doses strychnin does not raise the blood pressure materially, either in man or in animals. The rise of pressure, therefore, is a toxic effect; and, so far as we know, it is not available for therapeutic purposes. Due consideration must also be given to the fact that in the laboratory intravenous injections are frequently used, whereas in medical practice these are seldom given except in emergencies. Finally, different species of animals may vary in their reactions to a given drug. When the reaction is essentially the same in a variety of mammals, it may be assumed that the human organism will respond in a similar manner;

---

* Chairman's address, read before the Section on Pharmacology and Therapeutics at the Sixty-Eighth Annual Session of the American Medical Association, New York, June, 1917.

but when the reaction varies, the effect on man cannot safely be predicted from laboratory studies. In practice, moreover, even lesser quantitative variations in response may become of paramount importance, for it is our purpose to secure therapeutic results, and at the same time to avoid unpleasant side effects.

One of the most important methods for helping to bridge over the gap between animal pharmacology and practical therapeutics is the accurate study of the ts produced when drugs are given in the usual inal doses to human beings. The methods loyed in making such studies must naturally be free from the possibility of doing harm. Fortunately a great variety of new methods have been developed in recent years which may be applied to the study of human functions. Without attempting to name all of these, I mention the following: bloodless determinations of the arterial and venous pressures; graphic records of the gastric contractions, of the arterial and venous pulse waves and of the electric changes accompanying cardiac activity; roentgenographic examinations of the alimentary tract; determinations of the rate of metabolism; chemical analyses of the alveolar air, of small quantities of blood and of excreta, and estimations of the various immune bodies in the blood. Each new method that can be applied to the study of human functions not only advances our knowledge of these functions and of their perversions in disease, but also makes possible more accurate studies on how functions are influenced by various remedial measures. In many cases such studies can be carried out on normal individuals, and within a short space of time sufficient data can be accumulated to establish with scientific accuracy certain aspects of drug action.

Ultimately, however, we must answer the question: Are these drug effects of value in combating the disturbances of functions that are encountered in disease? The final answer to this question can seldom if ever be given from studies either on normal animals or on normal men. In certain instances the diseased function is unusually susceptible to drug action. The body temperature of a febrile patient, for example, is reduced more easily by antipyretic drugs than is the body temperature of a normal person. Digitalis in therapeutic doses has relatively little effect on the heart rate when this is controlled in the usual way from the sinus region. Its reputation for slowing the heart of patients is based almost exclusively on observations which were made on those suffering from auricular fibrillation. Diuretics of the caffein group produce a moderate diuresis in the healthy man, and may be ineffective or harmful in nephritic edema, whereas in cardiac edema they often cause a veritable flood of urine. The dilatation of the bronchi produced by epinephrin is most plainly demonstrable in conditions of bronchial constriction, whether produced experimentally or occurring during asthma. Finally, the treatment of infections can manifestly be tested only on infected animals or human beings.

Not infrequently the remark is made that the value of a therapeutic measure is determined solely by clinical experience. While I have no desire to contradict this assertion, it should be pointed out that ordinary clinical observations are often extremely difficult to interpret, owing to the vagaries of disease and to the many remedies that are so commonly employed in a single case. The past history of therapeutics warns us that in order to avoid error we need as much assistance as possible from every source. Pharmacology may not, indeed, answer therapeutic problems directly, but at least it aids in their solution. It shows how drug action may be made the subject of accurate study, and the critical attitude which it adopts must be carried over into the interpretation of therapeutic results, if progress in that subject is to be placed on a firm foundation.

On the other hand, pharmacologists could, I believe, be of greater help to those who work in the clinic if they would fully realize how their results may be given a form more suited to clinical needs. What, for example, is the effect of a given drug in small doses, especially when given over a long period of time? How are the effects modified when animals have been made the subject of disease? What pharmacologic problems can be studied on man himself, and especially on patients who are taking the treatment usually given for their disease? Work on such lines as these whether by pharmacologists or by clinicians, will help to maintain contact between the science of drug action and the art of treatment.

THE PROTECTION OF THE HEALTH OF THE WORKER IN WAR *

W. IRVING CLARK, Jr., M.D.
WORCESTER, MASS.

The preservation of the health of the war worker is one of the most important problems of the next two years and one which, if a correct solution is found from a rational and practical standpoint, may lead to revolutionary changes in the majority of factories in the United States. The health of the war worker is a national asset, and must be scrupulously guarded along the most approved lines compatible with present factory administration. It must be remembered that any revolutionary project, no matter how carefully thought out, is potentially destructive, and that the greatest care must be taken in introducing reforms and changes to do so in such a way that maximum results can be obtained with a minimum amount of expense and change from existing conditions. In this paper I shall present briefly the experimental and practical data which apply to the protection of the health of the war worker, and a definite system of organization which is applicable to all factories doing war work and employing 1,000 or more employees.

HEALTH IN RELATION TO PRODUCTION

"Health is a condition of physical soundness or well being in which an organism discharges its functions efficiently."[1]

To maintain health means to maintain working efficiency, while reduction of health means loss of efficiency. Sickness decreases the individual's production, increases the risk of accident, and militates against the efficiency of the department. An epidemic of sickness can completely disorganize a department or even a whole shop.[2]

Health may be affected (1) by outside factors (environment, fatigue, accident), and (2) by internal factors (disease and defects).

---

* Read before the Section on Preventive Medicine and Public Health at the Sixty-Eighth Annual Session of the American Medical Association, New York, June, 1917.

[1] Encyclopaedia Britannica, Ed. 11, 13.

[2] Newman, George: Sickness and Injury, Memorandum 10, British Health of Munition Workers Committee, 1916.

OUTSIDE FACTORS

(*a*) *Environment.*—In factory work the health of the worker is menaced by three factors of environment, each of which can to a certain extent be overcome. These are poor ventilation (which should be coupled with heat and humidity), poor light, and dust. We will consider these briefly in order.

In muscular activity the glycogen of the muscle unites with oxygen from the blood, producing heat and combustion products, the most important of which is carbon dioxid. During work such as that done by the average factory worker, the amount of carbon dioxid thrown off in the expired air is about double the amount that is thrown off by the same person at rest. Along with this carbon dioxid there are thrown off by the working body emanations containing toxic protein products. These toxic products cause the odor and closeness of an ill ventilated room.

Recent investigation tends to show, however, that the lassitude, headache, and malaise experienced in a close atmosphere are due to heat and humidity rather than to the inspiration of waste products, and that the effect of heat and moisture on the skin is the determining cause of the discomfort. From these facts it is evident that not only must there be a free circulation of fresh air, but also the heat and humidity of the air surrounding the worker must be within certain definite limits. Briefly stated, factory air should not contain more than six parts of carbon dioxid in 10,000. The temperature should not, if it is possible to avoid it, exceed 68 F., and the humidity should not be higher than 72 wet bulb.

Good light is necessary not only for the health of the worker, but also for the efficiency of his work. This fact has been definitely realized in modern factory construction. Artificial illumination by electricity may be furnished by direct, indirect or semidirect methods of lighting. General semidirect supplemented by shaded individual lights probably give the best practical results. Each worker or group of workers can then control the light over the machine or group of machines being operated. The light should fall on the work, not on the operator's eyes. There are three dangers to be avoided: (1) overillumination, causing overstimulation of the retina and contracted iris; (2) underillumination, producing eye strain, and (3) reflected light from brightly polished metallic surfaces which tends to confuse and to produce the effect of overillumination. Poor illumination, besides injuring the worker and reducing the output, increases the number of accidents.

"The lighting of a factory is deemed to be insufficient if the illumination taken on the horizontal plane, 1 foot above the floor, falls below one third of a foot candle."[3]

(*b*) *Fatigue.*—"Fatigue is a diminution of the capacity for work which follows excess of work or lack of rest; and which is recognized on the subjective side by a characteristic sensation of malaise."[4]

No subject that has to do with industrial health has received more careful attention and consideration than industrial fatigue. The British Ministry of Munitions devotes a whole pamphlet or section of its report to its investigations and findings. Fatigue has also been exhaustively studied by Lee, Goldmark, Mosso and many others. Physiologically considered, muscular fatigue results from (1) poisons produced by contraction of striated muscle; (2) catabolism of the glycogen in the muscles, and (3) consumption of the glycogen stored in the muscles and the liver. Fatigue products are chemical substances acid in reaction. They consist of sarcolactic acid, monopotassium phosphates, and carbon dioxid. These substances circulating in the blood produce fatigue. They act not only on all the muscles of the body, but also on the central and end nerve cells. These waste products are eliminated slowly, and the body requires a period of rest for their complete elimination and the necessary tissue repair. If sufficient rest is not allowed between working days, a physiologic deficit must result. According to Goldmark,[5] "this is the essential injury of consecutive days, weeks and months of overtime work which we (shall) find common to many branches of industry — that the normal season of tissue repair between working days is cut down at the very time when the severest demands are being made on the human organism. Strain or work done after fatigue has set in not only costs more effort but accomplishes less."[2] This has been graphically shown by Lee:[6] "Effort increases with fatigue, but if work is reduced by one half the period of necessary rest can be reduced one half or three fourths as much again."

There are three stages of working power. In the first the working power gradually increases; it is the limbering up stage and is known as the stage of incitement. During this stage the output of the individual worker gradually increases. The second stage begins when the worker has gotten into full swing. This stage is known as the stage of practice; work becomes automatic, speedy and leaves free will for application to the general consideration of the work. After a certain period of time, the duration of which depends on the work, the physical condition of the worker and many other factors, the stage of fatigue is reached. This stage is usually characterized by a spurt or effort on the part of the worker to overcome the lassitude caused by fatigue products. These stages correspond to the action of isolated muscle electrically stimulated. Before fatigue reduces the contracting power of muscle there is a steplike rise, each contraction being more powerful than the last, until a certain height is reached, after which there is first a slow, followed by a rapid, fall in power. We must remember, however, the volitional control of the worker, and this is shown in the spurt. The spurt may occur at any time during the stage of practice, but it is particularly prevalent toward the end of a working period or during the stage of fatigue. This spurt is known as the end spurt, and "occurs where a worker makes a special effort to do his best before leaving off. This effort is coupled with a stage of excitement which is psychological depending on the approaching rest period. During this period accidents diminish."

It is evident on physiologic and psychologic grounds that overwork, an insufficient number of rest periods, and insufficiently long periods of rest all militate against the health of the worker, and increase the danger of accident.[7]

The type of work in different departments varies, and the physical condition of each worker varies. It is obvious, therefore, that to make hard and fast working hours for the whole factory, as is now done, is working a grave injustice on the workers of some departments and on the workers not physically fitted to work in certain departments. Therefore, I submit these principles: 1. Whenever possible, the working hours of a department should be governed by the type of work of the department. 2. Rest periods should be introduced as indicated by production and by the number of accidents. 3. In each department, only workers physically fit for the work of that department should be employed.

(*c*) *Accidents.*—Accidents are largely due to workers' so-called "carelessness." In a recent investigation of 1,000 accidents occurring at the Norton Company plant, 85 per cent. were found to be due to this cause. In many occupations, accident is undoubtedly due to monotony, breaking of rhythm, or complexity of work. The rendering of machinery safe is a science in itself, and large factories now employ safety engineers whose business it is to see that machines are fitted with the proper safeguards.

In the scientific consideration of accidents, injured workmen continuing to work should be classed and considered in the same way as are defectives, until they have completely recovered.

The proportion of accidents to sickness is generally considered very low. This is true in regard to time lost from work, but in actual numbers the records of the Norton Company show a remarkable equality. Thus, during the first three months of this year the number of employees applying for dispensary treatment was in the proportion of nineteen cases of sickness to twenty cases of accident.

Accidents should be treated promptly by trained assistants. When serious they should be treated by a physician. By prompt treatment I mean treatment within ten minutes of the time the accident occurs. The exact method of treatment of accidents has been discussed in a recent article.[8]

INTERNAL FACTORS

(*a*) *Defects.*—Physical defects militate against the health of a worker unless he is so placed that the character of his work and his mental ability allow him to keep up normal production without strain and without materially increasing the defect from which he is suffering. A defective worker is not by any means an inefficient worker. Inefficiency occurs only when the physical defect through fatigue or discomfort prevents the worker from producing a normal output. Often defective workers are the best workers in a department, but they will not remain so unless properly supervised. The method of supervision will be discussed later.

(*b*) *Disease.*—Sickness is prevalent among any large body of workers. It is most marked during the four winter months, and is an important factor in causing lost time. Our experience at the plant of the Norton Company during December, January and February, the worst months for sickness, showed that 27 per cent. of the men investigated were absent because of sickness, the remaining 73 per cent. being absent for personal reasons. Approximately 2 per cent. of the working force were absent each month because of sickness. It is obvious that sickness is probably the most important factor to be controlled in considering the protection of health, and I hope to show later the possibilities of reducing this to a minimum.

In considering the foregoing factors which control the health of the worker, it is evident that the responsibility for the workers' health falls on four men: the engineer of the plant, the safety engineer, the manager of the works, and the factory surgeon.

1. The engineer of the plant controls the external factors of environment.

2. The safety engineer controls the external factors of danger.

3. The manager of the works controls the external factors of fatigue.

4. The factory surgeon controls the internal factors of disease and defects.

No further consideration will be given the first three. Each is a specialty in itself.

We will now consider the work of the factory surgeon and the medical supervision of war workers.

The object of medical supervision is to control the health of the working force by instituting methods of prevention of disease and maintaining them; by the prompt attention to accidents and through careful after-care preventing disability as far as possible; by finding defects in workmen and repairing them, and if this is not possible, endeavoring to place the defective workman where he will be most efficient; by the education of the workman in matters of hygiene, and by the control of sanitation and matters pertaining to the health of the factory at large.

PHYSICAL EXAMINATIONS

The keystone of efficient knowledge of the physical condition of the worker is a physical examination. This fact is recognized in every hospital, college and army. With the knowledge gained by physical examination, defects discovered may be remedied, employees may be placed in departments in which their defects will not only not militate against their efficiency but where they may be actually improved. Workers may be stimulated to cooperate with the physician in helping themselves, and the close touch necessary for future supervision and advice established. The value of physical examinations to both factory and worker is becoming more plain each year.

Outside of the specific fundamental data obtained by the examination, perhaps the most important feature is the use of the knowledge thus obtained in placing defectives in their proper departments. With the Norton Company there are at present 401 defectives so placed that they are all doing excellent work and apparently improving rather than retrogressing.

Defects may be divided into two classes: (1) Those which can be relieved by medical supervision and by proper placing, and (2) those which can be assisted only by medical supervision.

In the first class belong defective eyes, defective ears, defective hearts, defective lungs, and certain defects of the extremities. Defective eyes and ears are of particular importance in certain office departments and in shop departments requiring keen vision in the work. Slight refractive errors if not corrected lead to eye strain and poor work, which is of advantage to neither factory nor worker. Slight deafness among stenographers using the phonograph causes great nervous strain, and such work should not be assigned. Defective hearts are more or less of a bugaboo. The average patient with compensated endocarditis is capable of considerable work without danger, provided sudden or prolonged strain is avoided. My experience tallies exactly with that of MacKenzie, who says: "If the rule that exercise should stop short of exhaustion be followed, it is surprising what an amount of effort can ultimately be endured by patients who may once have suffered from extreme heart failure. This will be appreciated by those who practice among the classes employed in hard manual labor."

---

[8] Clark, W. I.: Medical Supervision of Factory Employees, The Journal A. M. A., Jan. 6, 1917, p. 5.

The Norton Company has ninety-two workers with defective hearts. Only two of these men have been forced to stop work because of broken compensation, and both after a rest were able to return and are now working. All are, of course, under careful supervision. The question of the seriously defective lung is quite different. Here the function of the health department must be to make an early diagnosis of tuberculosis or pneumonia, and see that the worker receives immediate and adequate care. In neither condition should one be permitted to work, but outside treatment should be arranged. It seems remarkable that not only have many persons with tuberculosis applied to the Norton Company for work, but even a few with pneumonia.

The handling of defective extremities is such a broad subject that it cannot be considered here.

In the second class belong those numerous minor defects so common among workers which if not checked and cared for sooner or later lead to marked disability.

In order that no defective may be transferred from a suitable to an unsuitable department, another physical examination should be made on all transfers, and this, together with the examination which all sick employees should receive at the main or subhospital when applying for relief, obviates the necessity of periodic examination of the entire factory force. Workers with severe defects should, however, be kept under close supervision, and should be reexamined once every six months or year.

Medical supervision should begin with the physical examination of the applicant and continue as long as he continues to work in the factory. He should be provided with careful and thorough examination and advice when he is sick. He should be given prompt and efficient treatment for every accident, no matter how slight, and this treatment should continue until the worker is able to resume work. Medical supervision should preserve the general health of all workers by supervising hygiene and sanitation at the factory, and it should educate by affording an opportunity for direct contact between physician and worker, and by the distribution of leaflets simply and clearly written on health subjects.

The great bulk of sickness among workers is of a minor nature; but unless this is given careful treatment, much more serious conditions are likely to follow. Thus at the Norton Company's plant, where the number of employees in office and shop approximates 4,500, during the first three months of this year, 1,920 patients applied for treatment, of which only 319, or a little under one sixth, could possibly be considered more than minor cases. The whole comfort, and much of the efficiency of the worker, however, depends on the relief of these milder ailments, and many, if not cared for, tend rapidly to become serious.

When we are confronted with figures like these, we realize the necessity of a sickness prevention movement similar to "safety first."

In short, sickness among workers is as prevalent as accidents, and should receive the same care and attention as accidents, if we are to preserve the health of the war worker. The best index as to the amount of sickness and the number of accidents at a factory is the lost time record. This may be divided into time lost from sickness, time lost from accident and time lost for personal reasons. I consider the personal lost time as a normal for sickness. If the sickness curve is lower than the personal curve, good medical service is being provided, and workers are availing themselves of it. During the past year the average number of hours lost from accident per month at the Norton Company plant employing about 4,500 workers was 328, or about six weeks' working time. In other words, the lost time each month was equivalent to six injuries each severe enough to incapacitate one worker for one week.

Good results can be obtained only by keeping a most careful check on each case of accident and sickness and by an efficient follow-up system; in other words, a close personal touch is the keynote of success.

The whole question of the preservation of the health of the war worker resolves itself into education and service: education of the employer as to the economy of preserving the health of his employee; education of the employee as to how to live and how to avail himself of medical supervision. Once this education has been accomplished, success is assured. The proper service is now to be considered.

The instruments of service are the industrial physician, the industrial nurse and the industrial hospital. The industrial physician is a specialist. His equipment and training are special, and more closely approximate those of the military surgeon than any other branch of the profession. His duties and responsibilities have been outlined above. The industrial nurse is also a specialist, and should receive a special form of training. In my experience the most adequate training is that given in the United States Army or Navy Medical Corps. The industrial hospital is a combination dispensary containing both medical and surgical units. It must be equipped (1) to provide room for physical examination; (2) to provide equipment adequate for the treatment of accidents, and (3) to provide for diagnosing all general medical cases and for the treatment of minor medical conditions. These three factors form a unit, and this unit can be extended as far as necessary by multiplication. It is customary, in large factories, to have an employment department where all applicants for positions apply. Therefore, the hospital should be placed in close proximity to this department in order that applicants after being registered may step into the examining room for their physical examinations. This examining room should be in immediate communication with the hospital in order to save the physician's time. It becomes evident that the hospital in connection with the employment department becomes a medical supervisory center and should be situated in the topographic center of the factory if possible. Depending on this main hospital, secondary units may be thrown out, each one complete but small, these in turn being situated in topographic centers of activity throughout the plant. Each subhospital should be capable of caring for accidents and minor sicknesses, and should be in touch with the main hospital by telephone. Each subhospital is in charge of an industrial nurse. This system can be carried out almost indefinitely, is absolutely pliable, and can be adapted to any type of factory. In small factories of 1,000 employees a main hospital alone is necessary. In larger factories one or more subhospitals are placed as indicated by the necessity. One subhospital is capable of handling the accidents and sicknesses of a thousand employees. It therefore can be rapidly figured how many subhospitals will be needed for the service of the employees in a factory.

All records, including physical examinations, should be kept in the main hospital, and all cases appearing in subhospitals should have records made, copies of which should be sent to the central hospital, in order that this record may be entered on the original report of the employee.

An industrial physician should make the rounds of each subhospital daily, and should go over the subhospital records and find out exactly how each case is progressing. If there is any reason to suspect that an employee is not doing well, he should be summoned by telephone and seen by the physician personally. The nurse should also have ready for the physician on his arrival any case which he does not consider himself competent to treat. Any serious cases arising in the subhospitals should be referred at once to the main hospital, or the physician should be summoned from the main hospital to give the necessary treatment.

The advantage of this subhospital system is that every injury is treated within ten minutes from the time it occurs. Redressings are done with great rapidity without the patient's being obliged to wait. Minor injuries and minor sicknesses receive adequate attention at the hands of a specially trained nurse without requiring the time of the physician.

The expense of maintaining a subhospital is less than the expense of time lost by injured and sick employees going a long distance to the central hospital. The records are kept carefully by this method, as every case of injury or sickness is reported directly to the central hospital.

This system has been used by the Norton Company for a year. During that time the subhospitals have administered on an average twenty-five treatments each a day. In the large number of minor accidents treated we have had no case of sepsis.

It must be remembered, however, that only industrial nurses should be given this responsibility, and that the limits of their power to treat cases should be firmly fixed. The industrial physician should remember that he is absolutely responsible for every case thus treated, and should go over the nurses' records with this in mind.

In closing, I feel that I cannot do better than quote the report of the British Health of Munition Workers Committee:

> The committee have received evidence and reports from all parts of the country of the economic and industrial value of the proper organization of a medical service within the factory, and they are convinced that both on grounds of health and of securing improved output this subject demands the immediate attention of employers, and that adequate schemes of treatment, especially of minor injuries, are an important means of preventing loss of time and efficiency among the workers. They recommend, therefore, that provision for organized treatment should be made in every munition factory.[2]

37 Pearl Street.

ABSTRACT OF DISCUSSION

Dr. John R. Williams, Rochester, N. Y.: I think the study of the physical vigor of the worker is quite as important as the physical examination. By the use of the Collin dynamometer it is possible to measure and get a comparative estimate of the physical vigor of every person in this room in a few minutes. By making such observations under the definite conditions which one wishes to investigate, it is possible to determine whether or not the worker is being injured by the occupation.

I have employed this method with satisfactory results in some brief studies on the effect of undernutrition on certain persons. According to Dr. Ales Hrdlicka of the National Museum, Washington, the dynamometer as a means of measuring the muscular tone of the individual is quite as valuable a diagnostic instrument as is the thermometer or stethoscope. The effects of dissipation, bad food, worry, improper ventilation and fatigue, all have an appreciable effect on the muscular tone, which can be measured easily by this instrument. It seems to me that with this very simple apparatus we could readily determine whether the conditions in a factory were promoting the highest degree of efficiency in the worker.

Dr. David L. Edsall, Boston: In regard to Dr. Clark's paper, the present time is, as we know, a time in which things ought to be done as effectively as possible, and not from the accident of impulse. I want to urge the members of this section present, and other physicians whom they may influence, to make themselves familiar in detail with the reports of the British Health of Munition Workers Committee, from the standpoint of being able to give some wise advice to people from the hygienic standpoint; in regard to the control of industries at the present time under pressure because of the war.

Physicians, knowing this subject somewhat, ought to be familiar with those reports, at least they ought to be read, to give some wise advice as to controlling this matter, not through any patriotic impulse, which is wrong, if driving us to do too much, rather than to do a little; but do something based on better knowledge, based on the attitude of men like Dr. Clark, who has had much experience in it.

The other point is this: Medical men have properly had some feeling against the establishment position as that has sometimes been managed. I have not the slightest doubt that establishment physicians are here to stay and are going to increase in number, from the standpoint of doing work well for the public at large, as well as for certain employers of the people at large; but I have in mind that establishment physicians are going to increase, and going to increase in very great numbers, and more than there will be need to increase, unless the profession at large becomes more familiar with problems such as Dr. Clark has been describing. At the Massachusetts General Hospital in the past year or two we have had an industrial clinic running in the hands of Dr. Wright, just a big dispensary clinic of patients of industrial accidents and the effects thereof. He has seen in that time, in that one hospital, about 5,100 people who are exposed to very definite industrial accidents. They have not been recognized by the ordinary familiar methods. Dr. Wright has diagnosed in one year 147 cases of lead poisoning; and the doubtful ones were all proved by finding lead in the stools, or urine, or both. The physician needs to recognize, as Dr. Clark said, that this is technical work and needs technical training; and we need to recognize in the medical schools that we should teach the students something more about this than we have yet done; but the man who wishes to retain the power of competing against establishment physicians has still to recognize that he has got something there apart, but still has to learn it with an open mind, and to realize the fact that he does not know it.

Dr. J. W. Schereschewsky, Pittsburgh: You must remember that it is not men alone that win a war, but, coincidently, our ability to furnish the military establishments with all the supplies they can possibly need. Now the bulk of these supplies is something which we, used as we are to gigantic industrial operations, can hardly conceive of. If we are to wage this war effectively we must not forget the necessity for maintaining armies which may amount to several million persons. As these are necessarily able-bodied men, they reduce by that amount those available for industry. This means that not only must every industrial worker be more efficient than ever before, but that women must enter industries to a hitherto unprecedented extent.

In order to secure maximum individual effectiveness, we must not only carefully supervise the physical condition of the worker, but each individual must be placed under circumstances and in an environment enabling him to perform a maximum amount of work. Therefore, measures for the conservation of the health of workers are of vital importance to the country.

In order to secure this result, provision must be made for the following: (1) the establishment of minimum standards of industrial hygiene in work places; (2) prevention of occupational diseases and poisonings; (3) medical supervision of workers, and (4) community sanitation.

The object of all these provisions is, of course, not only to secure conditions favoring maximum production, but so to safeguard the health of workers that an absenteeism from preventable sickness shall be reduced to a minumum. One point which was brought out in Dr. Clark's paper must be insisted on, namely, the adaption of the worker to his job and the utilization of everybody, including physical defectives, to the fullest possible degree. We should by no means reject a skilled workman because of a certain minor physical defect, for if he is given work which can be satisfactorily performed without injury to the health, we can utilize him as effectively as though the defect had never existed. Finally, we must not lose sight of the necessity for creating good sanitary conditions in our industrial communities. It will not be enough for us to secure ideal factory conditions and effective supervision of the health of workers while in the working place unless at the same time we see that their surroundings after they leave the factory are also healthful.

The production of effective conservation and utilization of the resources of the nation in this period of national emergency evidently require the fullest cooperation of all the health resources of the country. We cannot hope to put forth our best efforts in carrying on this great struggle into which we have entered unless there is an effective union of all the health agencies of the country.

Dr. Oscar F. Dowling, New Orleans: Those of us who have been interested and have made investigations know that the best medical training is what we should set as the standard. Recently I had the pleasure of having some health officers say to me that when they got through and returned to their work they would show us "some sanitation." Camp experience has already convinced them that a county or town can be made healthful, something they did not believe a short time ago. If all the medical men not called to the front could serve a term in one of the camps, especially health officials, it would make for cooperation in the enforcement of protective measures. As it is, so few of them know anything of the value and effectiveness of this work.

This war will give us added respect for law. With us, and I presume it is true of every section, in theory the people have now a profound respect for the law, but once written, they think enforcement will take care of itself. No one feels responsible. We will now have an object lesson in the effect of obedience.

Dr. Herbert J. Cronin, Cambridge, Mass.: Dr. Clark's system of medical supervision of employees at the Norton Plant in Worcester is practically perfect. I would advise the physician, unacquainted with industrial medicine and about to establish medical supervision in a plant, to introduce Dr. Clark's system complete.

The operating expenses of medical supervision in industry must always be the serious consideration of the physician. A too expensive system may fail because the plant may feel that it cannot afford it. General managers ask, "How much does this cost?" Cost will interfere with your plans; it may even discourage you; but industry must be operated for a profit and a return demanded for money spent. The physician can show a large return if he proceeds slowly and spends cautiously. From my own observation of Dr. Clark's system, I consider it a most practical and inexpensive one.

The establishment of a first-aid hospital should be the first step for the physician on taking charge of the medical supervision of employees in industry. Gradually add the allied departments, such as physical examination of employees, visiting nurses, etc., but use the hospital as a center from which these other activities radiate.

Dr. R. W. Corwin, Pueblo, Colo.: The importance and benefit of first aid cannot be overestimated. The day is past when first aid can be neglected in any line of public industry; it must be considered in every branch of work, and, with equal justice, it should be extended to the home. The welfare of the man or employee should first be considered, then his family, and, last, the public or its representative, the employer, but all are vitally interested and should be keenly awake to its benefits and justice.

Dr. Otto P. Geier, Cincinnati: One point stands out which has not been mentioned, it seems to me, in connection with this paper and the discussion. We talk about shortage of labor and shortage of material; but there is bound to result a shortage of medical attendence as a result of the war. We point to the fact that over on the other side anywhere from 25,000 to 50,000 doctors have been withdrawn from attendance on the civil population. That will mean that there will be a shortage of 20 to 50 per cent. of medical attendance in this country, which in itself means a serious thing to the community and to labor. I think that the medical profession should take such steps as will intensify the plans of preventive medicine, as that is the only way to meet the extra service that is going to fall on the medical profession in this country. The industrial physician through his control of the medical problems of large groups of workers can assist considerably in meeting the problem.

Dr. W. Irving Clark, Jr., Worcester, Mass.: I urge every one to use every influence he has to have established in any factory that he may come in contact with medical supervision of factory employees, for three reasons: In the first place, because it is good for the employee; in the second place, because it is good for the community; in the third place, because it is good for production; and, if you want to put such a small thing in as the fourth place, it makes money for the factory. All of those points have been absolutely proved; and I simply want to make that one appeal to every one. I think that there is great danger at the present time of long hours and insufficient medical attention to the laborers. It is going to reduce the production; it is going to hurt the laborer; and if arrangements were made so that when a factory is established medical supervision is established with it as one of the definite departments of that factory, it would save both factory and workmen in a great many ways.

Contract Practice in the Netherlands.—The *Nederlandsch Tijdschrift voor Geneeskunde* states that an agreement has now been signed which puts an end to the discord between the organized profession and certain sickness insurance societies, especially those at Amsterdam. One of the ninety-five clauses in the contract is to the effect that the loss of membership in the national medical association automatically excludes from sickness insurance practice. The practice of the individual sickness insurance physician is restricted to 2,500 adults, and the income limit is, for the unmarried beneficiaries, 800 florins and for the married, 1,400 florins, allowing an extra 100 florins for each child after the first, to a maximum of five. The honorarium for the physician is at the rate of 3 florins per adult and 0.6 florins per child. (The Netherlands florin is a fraction over 40 cents.) For exceptional obstetric cases he is to get 10 florins, and for night visits, 1.50 florins extra. Other clauses state that the physician must not take money from the insurance patients, and do no insurance practice outside the societies signing the contract. A control bureau is provided for, with representatives from the physicians, the societies and pharmacists. The contract covers a five-year period, with optional renewal for three years further.

THE EARLY RECOGNITION OF MULTIPLE SCLEROSIS

WITH REPORT OF THIRTEEN CASES *

LEO M. CRAFTS, B.L., M.D.
MINNEAPOLIS

In the experience of European observers, disseminating multiple sclerosis is considered one of the most common organic diseases of the central nervous system, but is spoken of by American writers as of unusual occurrence, Church referring to it as uncommon. There is no evident reason why it should not occur as frequently in this country as abroad, and the only explanation for its infrequent recognition with us must be that many cases are at present overlooked; and if we are to withhold a positive diagnosis until the so-called classical syndrome of Charcot is presented in its entirety, or even a very close approach to this picture, a great majority of all cases of this exceedingly interesting and widely variant congeries will continue to pass unrecognized, for there is but a comparatively small proportion of all cases that present this grouping.

Close analysis of the commonly attributed etiologic factors, when applied to the life history of the process, must lead to the conclusion that the real cause or causes are as yet really entirely unknown. In what manner can previous acute infectious diseases, such as typhoid fever or pneumonia, traumatism, exposure or the puerperium act to initiate the development of succeeding foci of gliosis scattered with entire abandon throughout the sphere of the central nervous system, occurring, receding, with apparent clinical recovery, latent perhaps for years, again and again recurring and receding throughout a course of great chronicity? In what manner is it possible for these long past incidents to so affect the organism as to cause the repeated turning into the blood stream of some genetic agent, probably autotoxic in nature, to attack here and there limited patches of white or gray matter, destroying the myelin sheaths, leaving the naked axis cylinders and the cells largely intact and functioning, although suffering to some extent degenerative effects?

The only conceivable manner in which they can possibly operate, if at all, must be by establishing in the multiglandular system some vice of secretion, thus disturbing metabolism and at intervals pouring a toxin into the circulation. The alternative possibility, setting aside the usually attributed factors, would be some microbic agent acting directly or through its toxins. There is at present no conclusive proof whether the causes are endogenous or exogenous. Krafft-Ebing and Strümpell deny the importance of infectious diseases; Redlich believes the cause is exogenous; Strümpell and Hoffman incline to the endogenous origin of the process, and the peculiar characteristics of the disease certainly favor their position, for in a great majority of all cases no sufficient cause can be found.

In my series of thirteen cases no possible causative factors, even remote, could be found in six. Quite severe trauma had occurred in two, but in each case it antedated the initial symptom by a period of two years, too far in the past to be rationally included as a cause. In two others there had been exposure, one incidental to a country practice and the other to a farmer's life, while with two that gave a history of previous infectious disease, years had intervened. When we consider the many who suffer from these infections and do not develop multiple sclerosis, and the few who do, they cannot be logically regarded as causative unless the sequence is immediate or close. All the cases in this series are of a distinctly or highly neurotic type.

In sharp contrast to the entire uncertainty of all initial etiologic factors is the clear and striking influence of trauma and the puerperium in promoting the recrudescence of symptoms. The importance of both these factors is notably illustrated in Case 1:

REPORT OF CASES

Case 1.—Mrs. W. M. D., aged 30, housewife, came under observation, Jan. 22, 1917, having been referred by Dr. A. A. Laurent. Her family history was good, but she had had much trouble with tonsillitis as a child. When 15 years old she got wet at the time of her menstrual period. This was followed by what was called "dropsy" in the legs, and she could not walk without support at this time. She recovered and was married at the age of 17 and has had eight children. Following the birth of a child four years ago she could not walk well; the legs felt clumsy, and became almost powerless in five months; but she gradually got so she could walk quite well (never naturally), but could not run. With the birth of a child seven years ago she had weakness in the left arm. This hand was numb for a time, with the attack four years ago. At that time she had a severe fall on the steps and thinks she was made permanently worse by it.

About two years ago, after the birth of a child, her legs began to grow worse, and numbness again developed in the left hand. She had another fall at this time and was numb to the waist for three weeks, and the left leg has dragged more since then. This leg has always been the weaker. At times she has a sensation as if something were dropping in front of the eyes—black spots and flashes. She had a little trouble with speech seven years ago, and friends tell her that her voice has changed. She had some occipital headaches two years ago. Her memory is somewhat impaired. She has pyorrhea and several devitalized teeth. She is subject to sharp and sudden changes in ability to walk. She is in a good state of nutrition and has good color. She has a slight hitch in speech at times. The right pupil is somewhat the larger; both react sluggishly. There is an irregular moderate lateral and vertical nystagmus. The facial muscles and tongue are free. The right tonsil is large and has some pyorrhea. The reflexes at the right elbow are sharper than at the left. The patellar responses are sharply overactive and equal. There is no clonus, but there is a Babinski reflex on both sides and an Oppenheim sign on the left. While abdominal reflex is lacking, epigastric is present and greater on the left. There is slight diminution of tactile sense over the left hand. There is distinct ataxia of station and the gait is uncertain and somewhat stiff. Steps are short, with moderate limp in the left foot. There is no intention tremor, but some incoordination. A roentgenogram of the spine was negative. The eye grounds are normal. The Wassermann test of the blood was negative.

Case 2 shows the importance of the puerperium alone:

Case 2.—Mrs. V. B., aged 23, came under observation, Nov. 1, 1915. She was seen in consultation with Dr. J. H. Higgins. The family history was not significant.

The patient had measles at the age of 3, but no other acute illnesses, accidents or exposure. She was always anemic and suffered from chronic constipation. At the age of 19 she suddenly noticed that the hands were clumsy and shaky when she tried to use them. A day or two later she found difficulty

* Read before the Section on Nervous and Mental Diseases at the Sixty-Eighth Annual Session of the American Medical Association, New York, June, 1917.

* Because of lack of space, this article is abbreviated in The Journal. The complete article appears in the Transactions of the Section and in the author's reprints. A copy of the latter will be sent by the author on receipt of a stamped addressed envelope.

in walking, staggered, and had to hold something for support. There was some difficulty also in speech. This condition continued for three months, then largely but not completely cleared up. Numbness has been present in the hands and feet, but has now entirely disappeared. Speech also has become normal. There was also some dizziness. She gave birth to a child in May, 1915, and soon afterward noticed difficulty in walking and a numb feeling in the hands and feet. She had dizzy attacks, and in about two weeks got so she could not stand alone. She could not write legibly for a long time. No trouble was noticed with her speech. The right leg has been worse than the left. She is pale and poorly nourished. The pupils are negative. There is a quite marked nystagmus, lateral, rather slow, of quite wide amplitude and jerky. The corneal reflex is active, the pharyngeal somewhat slow. The face reflexes are negative, the face muscles free. The arm reflexes are negative; the grip weak and equal. The hands show very slight tremor and distinct incoordination. The gait is spastic-ataxic, chiefly ataxic, and there is marked ataxia of station. Speech is good. The patellar reflexes are overactive and about equal. Achilles reflex, clonus, and the toe sign of Babinski were demonstrated. Oppenheim and Gordon signs were present on the right, and there was a slight Babinski reflex on the left. The pulse was 72; pressure, 120 systolic, 85 diastolic; sounds clear. There was distinct improvement under fibrolysin. The patient was seen again, Feb. 17, 1917. She was now able to walk alone with difficulty; the condition varied at times, but in the main was stationary. During the past week the vision had become very dim; she could not read ordinary type at all. Dr. Pratt reports nothing except pallor of the disk. Vision is not improved by refraction.

The characteristic oscillation of the hand, or it may be of the head or leg, commonly denominated intention tremor, is distinct from the element of incoordination, but is probably closely allied with it. This occurs in only a moderate percentage of cases, and not always continually. Speech defects vary from a simple flat or monotonous tone, or slight dysarthria, to stuttering or occasionally showing complete scanning type, being present in only two cases here recorded, while some form of disturbed articulation was found in eight. One of the most frequently observed motor phenomena is nystagmus, said by Redlich to occur in about 50 per cent. of all cases. If the eye muscles are tested by being put in position of extreme imbalance laterally or vertically, a distinctly larger proportion will probably show this sign, and it may vary widely in amplitude, rapidity and rhythm. It was readily demonstrated in eleven cases of this group, and in the remaining two, the patients had poor fixation of the globes. Diplopia is found occasionally, but is not frequent.

The pupils often show distinct inequality, one being larger than the other, but this difference is often variable, present at one moment and not at another, or it may be constant. The light reflex may be sluggish; accommodation is usually normal. Ordinarily the pupil is circular, and the iris never takes on that flat, tightly drawn tense look; the velvety softness is gone, a condition as characteristic of the tabetic eye as the Argyll Robertson sign, but which I have never seen mentioned in any text. Disturbances of vision are of moderate frequence, occurring early, according to Stölting; in about one third of all cases, being the exact percentage in this series. It varies from simple dimness to irregular restriction of the field or amblyopia, sometimes with a degree of optic atrophy or some choking of the disk.

In the congeries of symptoms, subjective and objective, that unfold before the observer, we approach a most fascinating study. While the advent of the initial manifestation is usually abrupt and marked, it may at times be vague and indefinite. Perhaps an irregular and patchy hysteroid area of disturbed sensation, involving one or all of the sensory percepts, may herald its advent, or an immediate loss, in part or whole, of motor power in one or more extremities, or sudden dimness of vision; and not infrequently an apoplectiform attack may prove the prelude to many scenes to follow, as occurred in the following cases:

TABLE 1.—SUMMARY OF FINDINGS

Possible Etiologic Factors:	
Trauma	1 (2 years previous), 1, (2 yrs)
Condition aggravated by trauma	2
Exanthems	measles at 3, pneumonia at 10
Condition aggravated by pregnancy	2
Neuropathic heredity	4
Marked pyorrhea present	2
Miscellaneous	anemia, 1, frail, 1
Exposure, including overtax	5
Tonsillitis	1
Gonorrhea	1
Age at onset	14, 15, 15, 19, 21, 23, 23, 25, 27, 37, 42, 45, 69
Initial Symptoms:	
Dimness of vision	1
Motor disturbances	5
Sensory and motor disturbances	2
Apoplectiform	3
Extreme headaches	1
Sex:	
Males	6
Females	7
Symptoms:	
Inequality of pupils, 55 per cent.	7
Sluggish reflex of pupils	2
Nystagmus, 85 per cent.	11
Poor fixation of globes	2
Speech disturbances	8, 60 per cent. (only two being true scanning)
Intention tremor	5 (3 of these slight)
Tremor of head	2, 53 per cent.
Paresthesias, including hypesthesia:	
Hypalgesia and thermal sense	11, 85 per cent.
Motor disturbances:	
Monoparetic	3, trophic changes (with fibrillation) 1
Paraparetic	7, 85 per cent.
Hemiparetic	1, propulsion, 1
Disturbances of coordination	10, 80 per cent.
Disturbances of Vision:	
Dimness	4, 35 per cent.
Diplopia	2
Qualitative Changes in Deep Reflexes:	
Heightened	11, 85 per cent.
Abolished	1
Changes in epigastric and abdominal reflexes (usually diminution or loss on one side)	10, 80 per cent.
Pharyngeal reflex absent	2
Control of bladder lowered	5
Stereognosis diminished	2
Spontaneous Remissions:	
Marked	9, 70 per cent.
Slight	1
One case too recent, but showing marked improvement under treatment	
Marked vertigo	4, 30 per cent.
Severe headache	4, 30 per cent.
Mental Effects:	
Lowered memory and attention	2
More emotional	1
Depression	1
Results of Treatment:	
Improved under fibrolysin	6
Not improved under fibrolysin	1
Now under treatment	1
Not treated	5
Wassermann and Nonne tests, and cell count	Negative in all cases tested, 5

Case 3.—Dr. J. P. V., aged 57, a physician, married, came under observation, Jan. 26, 1916. His father was of a nervous temperament, and there was also some tuberculosis in the family. The patient has worked had, and is of a nervous temperament. He had "writer's cramp" some years ago; he had also "neuritis" at the right shoulder, and intercostal neuralgia. He wrote with the left hand for a time. The right hand has never been fully useful since. He had a spell of sudden unconsciousness twelve years ago, with a good deal of dizziness after that. He is subject to sinking or fainting spells on exposure to cold or fatigue.

About three or four years ago he began having trouble with his speech; he could not pronounce words clearly, and a tremor of the head developed. He noticed also increased difficulty in the use of the right hand, and some tremor on closely adapted movement. He had no trouble with his legs. There has been no dizziness of late. He had some cramplike pain in the foot a year ago. He has control of the bladder, and there is no change in the sexual function. Color and nutrition are fair. He has a halting, tripping difficulty in speech, and the tone is rather flat. He uses his lips peculiarly in speaking. There is no nystagmus, but fixation is not sustained when looking to the left. There is some rhythmic tremor of the head at times; the right hand also shows tremor on movement, slight but distinct. Arm and leg deep reflexes are negative. Epigastric and abdominal reflexes are much less on the right than the left. The cremaster is normal; there are no disturbances of cutaneous sensation, and no aralysis; there is some pyorrhea. The pulse is 76; pressure, 24 systolic, 90 diastolic. The heart sounds are clear. The urine is negative.

Case 4.—Mrs. O. F. K., aged 45, came under observation, Feb. 6, 1917, having been referred by Dr. G. W. Bass. The family was of a nervous temperament on the mother's side. The patient was frail as a child up to 8 years of age. She was not fond of school; she was in the eighth grade at the age of 19. She had no serious illness. There were three children, all normal. When 15 years old she had "water on the left knee" for a year. One morning, three years ago, she had a sense of confusion, became unconscious, remained so for three days, and was in a dreamy state for several weeks. She has never felt well since then, is dizzy all the time, her memory is poor, and she is absentminded, has little interest in things, is inclined to be gloomy and cry, and is in a constant state of worry. The bowels are regular, and she has full control of the bladder. There is a numb and weak feeling in the left leg that is increasing. She often staggers about the house. She has cramps in the left lower leg at night, and also at times in the hands, The urine has been slow in starting the past four months. The patient is well developed and well nourished and her color is good, but her expression is dull. The right pupil is slightly larger than the left, but both are small and react poorly to light, somewhat better to accommodation. The arm reflexes are all sharply exaggerated and equal. The face reflexes are negative. Speech is free. Fixation of globes is not good, but there is no actual nystagmus. There is quite marked intention tremor in both hands. Patellar response is markedly increased on the right, less so on the left. There is no clonus, but a distinct Babinski and Oppenheim reaction on both sides. Station is fair; there is some ataxia of gait and the step is short, favoring the left leg. There is slight dulling of pain and tactile and thermal sense over the right arm and leg. There is marked anesthesia and analgesia throughout the left leg. Epigastric and abdominal responses are absent on both sides to stroke. Epigastric response is present on both sides to tap, but is distinctly greater on the right.

Usually the subject is a young adult under 30, there being no predilection for sex.

In the present analysis one began with extreme head pain, one with sensory involvement alone, five with pure motor disturbance, two with combined sensorimotor trouble, one with dimness of vision, and three with an apoplectiform picture.

The progress of the individual case is strikingly variant and irregular. Areas of paresthesia suddenly develop, extend or remain stationary for indefinite periods and gradually diminish or disappear. They may occupy any site, may be monoparesthetic, paresthetic, or hemiparesthetic in distribution. They may or may not be accompanied by corresponding disturbances of motor function. The gait may be slightly or profoundly affected, mostly spastic or almost entirely ataxic, and of the cerebellar type, this being evidently due to plaques in the peduncles.

The reflex phenomena are striking and significant. While a simple quantitative increase may possibly be the only alteration noted, in practically all cases there are definite qualitative changes, with either an ankle clonus, or the great toe sign developed in the Babinski, Oppenheim or Gordon test, on one or both sides, or perhaps a clonus on one and a Babinski on the other. In one rare case of my group, all these reactions were found on both sides.

Case 5.—Olaf O., aged 26, single, a Dane, entered City Hospital, Jan. 19, 1915. The family history shows no significant factors. The patient had pneumonia at the age of 10. He came to this country at 15. He is a heavy smoker and has had gonorrhea twice.

Three years ago he noticed difficulty in walking. He had chills and cold sweats. This improved for a time, but then became much worse; he could not stand or walk; the right leg was completely paralyzed. He took mud baths for three months, improving somewhat. The bowels are constipated, but he has control of the bladder. He has a sharp pain in the abdomen at times. The lower legs are cold. The vision is hazy. He has had headache for three weeks. The patient is well developed and in good nutrition. His manner is nervous, speech hurried but with slight trip in it. The right pupil is slightly larger at times. There is a marked rhythmic, lateral nystagmus of quite wide amplitude; there is reaction to light and accommodation.

The arm reflexes are sharply increased and equal, and there is no intention, tremor. There is slight incoordination in the arms; very slight diminution in tactile sense in the hands; marked unsteadiness in gait and station, and a spastic element. The legs show overextension at the knees. The patellar responses are sharply exaggerated and equal. There is ankle clonus on both sides. The great toe sign is present on both sides in all three tests. Appreciation of touch, temperature and pain stimuli is markedly reduced over both legs. The cremaster is active and equal. The epigastric and abdominal reflexes are abolished on the right and present on the left. For a time the right leg was much weaker, then gradually improved. The Wassermann test of the blood was negative. All reactions of the spinal fluid were negative.

Intramuscular injection of fibrolysin was employed for about two months, with apparent improvement in the use of legs and in vision.

While, as has been stated before, the reflexes are commonly heightened, in an occasional rare case they may be abolished, as they were in Case 6.

By some writers the superficial reflex reactions are not considered of material importance, but variations in the epigastric and abdominal responses are highly significant. They will usually be found active on one side and diminished or lost on the other. This was true in ten of these patients.

Disturbances in sense perception are not usually considered as frequent as those in the motor sphere, but if both subjective and objective changes are included they are probably fully as common and possibly more so; and thermal hypesthesia may be more pronounced than the diminution in either tactile or pain sense, as in Case 13.

Case 7.—Mrs. E. J., aged 35 years, housewife, came under observation, May 14, 1917. She was seen in consultation with Dr. E. G. Warne, St. Paul. The family history was negative. The patient comes from a family of very large people, and she was always large for her age. She matured at the age of 11. When 14 she had trouble with dimness of vision, and had glasses fitted. She was told she had cataract. The vision gradually cleared entirely. She had no material illnesses as a child. She was married at the age of 18, had two children, the last fourteen years ago, and she had several abortions, the last eight years ago. When about 20, she had trouble in walking. From time to time she has had numbness in the extremities, worse in the right hand and left foot. Vision at times has been misty and then cleared; she thinks she sees better in the evening. She has sudden temporary increase in the difficulty in walking or the feeling of numbness. Several years ago she had an interval of severe headache; dizziness is constant. Fifteen years ago she had a large fibroid removed. Menstruation is growing gradually less. Last summer she had a faint feeling; everything grew black.

TABLE 2.—ANALYSIS OF CASES

Case No. and Age at Onset	Causative Factors (?)	Initial Symptom	Motor Disturbances	Sensory Disturbances	Speech	Eye Symptoms	Reflexes	Remission (spontaneous)	Serology	Trauma and Puerperium
1—15	Exposure to wet; tonsillitis	Paraparetic	Paraparetic; spastic ataxic gait	Numbness; slight dim. touch, temp. and pain; head pain	Dysarthric (slight)	Nystagmus, both vertical and lateral; inequality of pupils; dimness	Patellar sharp, right; Babinski, both; Oppenheim, left; abdominal diminished, right	Marked	Not taken	Marked recurrences with both trauma and puerperium
2—19	Measles at 3; anemia	Arms clumsy and shaky	Paraparetic; difficulty in writing	Numbness; (subj.); dizziness	Dysarthric	Nystagmus; dimness	Clonus, Babinski, Oppenheim, Gordon on one side	Marked	Not taken	Marked increase with puerperium
3—45	Overstrain (country doctor)	Apoplectiform	Monoparesis; tremor of head; intention tremor	Dizziness.........	Scanning	Poor fixation	All tendon responses negative, abdominal diminished on one side	Moderate	Not taken	
4—37	Constitutional frailty	Apoplectiform	Intention tremor; spastic-ataxic; weak detrusor	Numbness; marked dim. all sense perceptions left leg	......	Poor fixation; inequality of pupils	All sharp: Babinski and Oppenheim; abdominal diminished on left	....	Not taken	
5—23	Pneumonia at 10; gonorrhea	Difficulty in walking	Monoparesis; spastic-ataxic	Marked dim. touch, pain and temp. perceptions; head pain	Dysarthric (slight)	Nystagmus; dimness; inequality of pupils; diplopia	All sharp, clonus. Babinski, Oppenheim, abdominal absent on one side	Moderate	Not taken	
6—42	....	Extreme head pain	Intention tremor; gait, spastic-ataxic	Numb and prickly feeling; dizziness	Dysarthric flat tone	Nystagmus; diplopia; dimness of vision	Dull in arms, absent in legs, abdominal, absent on one side	Slight	Negative	
7—14	....	Dimness of vision	Paraparetic; spastic-ataxic	Numbness; dim. in heat percep.; slight astereognosis; dizziness; head pain	......	Nystagmus, vertical; inequality of pupils	Patellar sharp, Achilles absent, Babinski and Gordon left, Babinski and Oppenheim right	Marked	Negative	Faint feelings on exposure
8—15	Nervous temperament	Apoplectiform	Monoparetic; intention tremor; paretic gait	Numbness........	......	Marked nystagmus; inequality of pupils; diplopia	Clonus and Babinski on left	....	Negative	
9—69	Pyorrhea	Paraparetic	Diplegic; trophic wasting; spastic-ataxic, weak vesical sphincter	....	Dysarthric (slight)	Nystagmus	Patellar sharp; clonus and Babinski	Moderate	Not taken	Aggravated by trauma
10—23	Nervous temperament	Local area of numbness	Paraparetic; almost purely ataxic gait; weak vesical sphincter	....	......	Nystagmus	Pharyngeal absent; Babinski and Oppenheim on both sides; abdominal absent right	Marked	Negative	Recurrence with overstrain
11—27	Trauma two yrs. previous	Paraparetic	Intention tremor (slight); spastic-ataxic	Slight local paresthesia; slight astereognosis	Scanning	Marked nystagmus; inequality of pupils; dimness	All sharp, Babinski, Oppenheim, Gordon, both sides; abdominal abolished	....	Negative	
12—21	Nervous temperament	Weakness and numbness in legs	Intention tremor (slight); marked incoordination; spastic-ataxic	Numbness........	......	Slight nystagmus	Clonus, Babinski, Oppenheim, both sides; abdominal absent one side	Marked	Not taken	Faint feeling from any exposure to cold
13—25	Trauma two yrs. before	Monoparetic	Monoparetic; slight incoordination; weak detrusor	Numbness; slight dim. tactile, marked of thermal perception	Flat tone	Nystagmus; inequality of pupils	Patellar inc. on right, Oppenheim and Gordon on right	Marked	Not taken	Recurrence following trauma

She had another attack four weeks later which lasted several hours, although she was not entirely unconscious. She tires easily, and the difficulty in walking and the numbness are aggravated. There is no diplopia. She had tremor of the head for a time. She could not write last winter. She had her feet scalded and she did not know the water was hot. There was loss of control of bowel and bladder for a time last winter. Control is now partially restored. She is very large, and weighs 240 pounds; her color is good. The left pupil is large at times; both react. The jaw jerk is sharp; the teeth show much dental work, the arm reflexes are negative. There is no tremor of the hands. There is a marked vertical nystagmus on looking to the left, but slight when looking to the right, of rather wide amplitude and somewhat irregular. Patellar response is sharply overactive and equal. Achilles reflex in absent on the left and slight on the right. There is no clonus. A Babinski and Gordon response on the left and irritation of the skin on the dorsum of the foot produces extension of the great toe. There is a Babinski and Oppenheim response on the right, and there is extension of the great toe on irritation of the skin just above the ankle. There is slight incoordination in the hands. The patient has a spastic-ataxic gait, slight diminution in tactile and pain sense and marked loss of thermal sense; also slight astereognosis in the right hand. The pulse is 84; pressure, 138 systolic, 105 diastolic (radial).

Stereognosis may be occasionally affected. Difficulty in either holding or passing the urine, transitory or more continued, is not infrequent. More or less severe and persistent vertigo is rather common, severe headaches are not considered a frequent occurrence, but were noted in more than one fourth of these cases. Intellection is not materially compromised, but there may be slight reduction, and somewhat lowered power of memory on increased emotionality.

Ordinarily there is little difficulty in arriving at a positive diagnosis. The clinical combination is unique, presenting both cerebral and spinal symptoms pointing to multiple, widely separated foci. It is not important what these individual symptoms are, provided we have any one characteristic spinal and cerebral sign combined. It may be, for instance, a clear lateral or vertical nystagmus and motor disturbance in one leg, including qualitative disturbances in the deep reflexes, which constituted the picture in Case 8.

Case 8.—Miss Martha W., aged 19 years, was referred by Dr. M. J. Jensen, and came under observation, June 19, 1916. Her family history shows no important elements. Her health was good up to four years ago, when she had a "fainting spell." She had another two years ago and a third a few months ago.

About a month ago she noticed numb feelings in the left hand (the patient is left handed). She has had some diplopia at times. For several weeks she has noticed that she could not use the left leg naturally, dragging the foot. She has not noticed any trouble with speech. She has very little headache, but some dizziness. There is no trouble with the right nutrition are fair. He has a halting, tripping difficulty in speech, and the tone is rather flat. He uses his lips peculiarly in speaking. There is no nystagmus, but fixation is not sustained when looking to the left. There is some rhythmic tremor of the head at times; the right hand also shows tremor on movement, slight but distinct. Arm and leg deep reflexes are negative. Epigastric and abdominal reflexes are much less on the right than the left. The cremaster is normal; there are no disturbances of cutaneous sensation, and no paralysis; there is some pyorrhea. The pulse is 76; pressure, 124 systolic, 90 diastolic. The heart sounds are clear. The urine is negative.

Case 4.—Mrs. O. F. K., aged 45, came under observation, Feb. 6, 1917, having been referred by Dr. G. W. Bass. The family was of a nervous temperament on the mother's side. The patient was frail as a child up to 8 years of age. She was not fond of school; she was in the eighth grade at the age of 19. She had no serious illness. There were three children, all normal. When 15 years old she had "water on the left knee" for a year. One morning, three years ago, she had a sense of confusion, became unconscious, remained so for three days, and was in a dreamy state for several weeks. She has never felt well since then, is dizzy all the time, her memory is poor, and she is absentminded, has little interest in things, is inclined to be gloomy and cry, and is in a constant state of worry. The bowels are regular, and she has full control of the bladder. There is a numb and weak feeling in the left leg that is increasing. She often staggers about the house. She has cramps in the left lower leg at night, and also at times in the hands. The urine has been slow in starting the past four months. The patient is well developed and well nourished and her color is good, but her expression is dull. The right pupil is slightly larger than the left, but both are small and react poorly to light, somewhat better to accommodation. The arm reflexes are all sharply exaggerated and equal. The face reflexes are negative. Speech is free. Fixation of globes is not good, but there is no actual nystagmus. There is quite marked intention tremor in both hands. Patellar response is markedly increased on the right, less so on the left. There is no clonus, but a distinct Babinski and Oppenheim reaction on both sides. Station is fair; there is some ataxia of gait and the step is short, favoring the left leg. There is slight dulling of pain and tactile and thermal sense over the right arm and leg. There is marked anesthesia and analgesia throughout the left leg. Epigastric and abdominal responses are absent on both sides to stroke. Epigastric response is present on both sides to tap, but is distinctly greater on the right.

Usually the subject is a young adult under 30, there being no predilection for sex.

In the present analysis one began with extreme head pain, one with sensory involvement alone, five with pure motor disturbance, two with combined sensorimotor trouble, one with dimness of vision, and three with an apoplectiform picture.

The progress of the individual case is strikingly variant and irregular. Areas of paresthesia suddenly develop, extend or remain stationary for indefinite periods and gradually diminish or disappear. They may occupy any site, may be monoparesthetic, paresthetic, or hemiparesthetic in distribution. They may or may not be accompanied by corresponding disturbances of motor function. The gait may be slightly or profoundly affected, mostly spastic or almost entirely ataxic, and of the cerebellar type, this being evidently due to plaques in the peduncles.

The reflex phenomena are striking and significant. While a simple quantitative increase may possibly be the only alteration noted, in practically all cases there are definite qualitative changes, with either an ankle clonus, or the great toe sign developed in the Babinski, Oppenheim or Gordon test, on one or both sides, or perhaps a clonus on one and a Babinski on the other. In one rare case of my group, all these reactions were found on both sides.

Case 5.—Olaf O., aged 26, single, a Dane, entered City Hospital, Jan. 19, 1915. The family history shows no significant factors. The patient had pneumonia at the age of 10. He came to this country at 15. He is a heavy smoker and has had gonorrhea twice.

Three years ago he noticed difficulty in walking. He had chills and cold sweats. This improved for a time, but then became much worse; he could not stand or walk; the right leg was completely paralyzed. He took mud baths for three months, improving somewhat. The bowels are constipated, but he has control of the bladder. He has a sharp pain in the abdomen at times. The lower legs are cold. The vision is hazy. He has had headache for three weeks. The patient is well developed and in good nutrition. His manner is nervous, speech hurried but with slight trip in it. The right pupil is slightly larger at times. There is a marked rhythmic, lateral nystagmus of quite wide amplitude; there is reaction to light and accommodation.

The arm reflexes are sharply increased and equal, and there is no intention tremor. There is slight incoordination in the arms; very slight diminution in tactile sense in the hands; marked unsteadiness in gait and station, and a spastic element. The legs show overextension at the knees. The patellar responses are sharply exaggerated and equal. There is ankle clonus on both sides. The great toe sign is present on both sides in all three tests. Appreciation of touch, temperature and pain stimuli is markedly reduced over both legs. The cremaster is active and equal. The epigastric and abdominal reflexes are abolished on the right and present on the left. For a time the right leg was much weaker, then gradually improved. The Wassermann test of the blood was negative. All reactions of the spinal fluid were negative.

Intramuscular injection of fibrolysin was employed for about two months, with apparent improvement in the use of legs and in vision.

While, as has been stated before, the reflexes are commonly heightened, in an occasional rare case they may be abolished, as they were in Case 6.

By some writers the superficial reflex reactions are not considered of material importance, but variations in the epigastric and abdominal responses are highly significant. They will usually be found active on one side and diminished or lost on the other. This was true in ten of these patients.

Disturbances in sense perception are not usually considered as frequent as those in the motor sphere, but if both subjective and objective changes are included they are probably fully as common and possibly more so; and thermal hypesthesia may be more pronounced than the diminution in either tactile or pain sense, as in Case 13.

Case 7.—Mrs. E. J., aged 35 years, housewife, came under observation, May 14, 1917. She was seen in consultation with Dr. E. G. Warne, St. Paul. The family history was negative. The patient comes from a family of very large people, and she was always large for her age. She matured at the age of 11. When 14 she had trouble with dimness of vision, and had glasses fitted. She was told she had cataract. The vision gradually cleared entirely. She had no material illnesses as a child. She was married at the age of 18, had two children, the last fourteen years ago, and she had several abortions, the last eight years ago. When about 20, she had trouble in walking. From time to time she has had numbness in the extremities, worse in the right hand and left foot. Vision at times has been misty and then cleared; she thinks she sees better in the evening. She has sudden temporary increase in the difficulty in walking or the feeling of numbness. Several years ago she had an interval of severe headache; dizziness is constant. Fifteen years ago she had a large fibroid removed. Menstruation is growing gradually less. Last summer she had a faint feeling; everything grew black.

temperament and his mother "at times dragged a foot." The patient is the youngest of six children. His father was 54, the mother 44, when he was born. He is of a nervous temperament, but his health was good until about eight years ago, when, while working very hard, he began to notice a drop in general condition of health. Then numbness came on in the right arm and side of the body down to the groin; this lasted for five months. In 1912 a numb area developed in the left arm and side of the neck but cleared in about a month. In 1913 the feet and lower legs were numb for about a month and in 1914 he had several numb patches over the body. Some difficulty in walking accompanied this attack, which cleared up in about a month's time. He has been a heavy smoker and has used a good deal of coffee. The present attack came on about a month ago. He had been carrying more responsibility than usual before this occurred. Numbness developed, with difficulty in walking, the lower body and legs throughout being numb. He has a little difficulty in holding the urine. There is no venereal history.

The patient is well developed and in good nutrition, with a highly neurotic eye. He is prematurely gray. The pupils are negative. The field of vision is apparently normal. There is a distinct lateral nystagmus of moderate amplitude. Pharyngeal reflex is absent. The ears are large and prominent, the hands steady. The arm reflexes are negative, and the patellar response is overactive and equal. There is no clonus. Both great toes show a slight but distinct upward tendency to both Babinski and Oppenheim tests. The epigastric and abdominal reflex is absent on the right. There is a slight epigastric reflex on the left. There is no objective loss of sensation. The gait and station are good. A quite marked incertitude in gait developed shortly after the first examination, with only slight spastic elements. The urine is negative, and the blood and spinal fluid are negative.

Six ampules of fibrolysin were given, resulting in rapid improvement in gait, which became practically normal in a month; nystagmus was much diminished.

Disturbances in the gait, the pupil and the sensory sphere are the only possible points of remote resemblance to locomotor ataxia, those of sensation being the most similar. The gait is markedly different. While the pupils may vary in size in both conditions, in locomotor ataxia they are irregular in outline, and response to light is affected and the iris has lost its normal velvety softness of texture and has a tense flat look like a tightly drawn curtain, presented earlier in this context as a new sign in that disease. There is less excuse for confusing these two diseases in diagnosis than almost any other that can come into consideration, and yet the following classical Charcot syndrome was designated as tabes even by a neurologist:

Case 11.—Miss K., aged 35 years, came under observation, April 19, 1916, having been referred by Dr. A. Gullickson. There was nothing of note in the family history. The patient was well until 20 years old, when she was thrown out in a runaway and was unconscious for perhaps five minutes. There were no surface injuries, although she was slightly lame for a time. About two years later trouble began in the use of her legs. This has steadily increased down to the present time. Slight trouble in holding the urine began about five years ago. This difficulty has increased slightly. There has been no trouble with the bowel. There has been some peculiarity in sensation in the left thumb and forefinger for the past two years. She has had some difficulty in getting words at times. Her vision is somewhat dimmed. There is no vomiting, headache or dizziness, and no diplopia. Her memory is normal. Menstrual periods have been too frequent of late. She is gradually losing flesh, and is quite emotional and irritable.

The patient is poorly nourished, and her face is highly flushed. The pupils are moderately dilated, the right being distinctly larger than the left. Reactions are sluggish to both light and accommodation. There is marked nystagmus of moderate amplitude, lateral, and more toward the right. She has several devitalized teeth. The throat is negative. There is slight tremor of the left hand on closely adapted movement. Her handwriting is very irregular. There is slight diminution of sensation in the left thumb and forefinger, and slight astereognosis. The arm reflexes on the left are sharper than on the right. Patellar reaction is decidedly overactive, greater on the right. Clonus is nearly sustained on the left, and there is a Babinski, Oppenheim and Gordon response on both sides, more marked on the left. There is decided ataxia of station. The gait is spastic-ataxic. Abdominal and epigastric reflexes are absent on both sides to stroke, but slightly responsive on the right to tap. There is slight dulling of tactile sense over the legs. Pain perception is normal. There is distinct slurring and trip in speech, but not actually scanning. The pulse is 72; pressure, 122 systolic, 90 diastolic (radial). A Wassermann test was not made.

The patient is very emotional and irritable. There is an element of propulsion in the gait. She was under observation for six months, a total of about 30 ampules of fibrolysin being used, with distinct gain in general nutrition, control in walking and in strength.

The course of multiple sclerosis is one of great chronicity, extending over a period of many years. Symptoms develop, are added to, shift or remain stationary for indefinite periods, or recede and disappear spontaneously, to remain latent perhaps for years, only to again recur, sometimes with identical, sometimes with widely different manifestations. This remarkable characteristic makes conclusions on the effect of any medication very uncertain; but when we find prompt and distinct improvement beginning and continuing on the administration of any medication, it is fair to conclude that it exercises at least some beneficial influence over the process. In this series of thirteen patients five did not remain under observation; of the others one showed no improvement with intramuscular injection of fibrolysin, one has only begun treatment, and the remaining six all showed either moderate or decided improvement, one with rapid and practically complete disappearance of all symptoms. Whether further recurrences will be influenced at all is at present uncertain; and the presentation of this paper with its limited group of case reports has been prompted chiefly by a desire to stimulate interest in closer attention to the protean pictures presented by disseminating multiple sclerosis; its earlier and more frequent diagnosis, as well as a more critical study of its causes, and possibly better methods of treatment.

ABSTRACT OF DISCUSSION

Dr. A. L. Skoog, Kansas City, Mo.: The differential diagnosis of multiple sclerosis from cerebral syphilis is often difficult to make. There is a diffuse arteriosclerosis affecting the brain and spinal cord. The diffuse scleroses perhaps do not fall under the group of multiple sclerosis. It has been said that we need not consider syphilis as a cause of multiple sclerosis simply because the serologic tests give the sign. I agree heartily with this. When we consider the large number of persons afflicted with syphilis, it is not surprising that some of them develop multiple sclerosis. We have had illustrated the same fact with tumors of the brain. I wish to cite a case under my observation about one year. The man was doing interior decorating on a government building when he developed his first symptoms of multiple sclerosis. A number of volatile oils were used in this work. He was informed by physicians and believed that his trouble was caused by inhalation of these fumes. The other workers did not work as long hours as he did. The onset was rapid, making one think of acute multiple sclerosis. During the past year the disease has taken the ordinary course, and now he has all the classical symptoms. He is in a bedridden, helpless state. Serologic analyses are negative. Personally, I do not think the volatile oils had anything to do with causing the disease. I believe multiple sclerosis is caused by some teratologic defect which becomes evident at a selected development epoch.

Dr. E. E. Mayer, Pittsburgh: Believing, as I do, in the infectious origin of multiple sclerosis, Minneapolis must be a very unhealthy place. I am surprised at the large number of cases that Dr. Crafts has observed. Even at as high a percentage as is observed in institutions, namely, about 1 per cent. of all nervous diseases, his number averages high. We do not secure many necropsies in Pittsburgh. A consultant, I believe, in the early stages cannot often positively diagnose multiple sclerosis. The family physician rarely returns these patients for further study, and if they go to state institutions we lose track of them. My low number of multiple scleroses may be accounted for in that way. But the many multiple inflammatory myelo-encephalitic processes and the numerous cases of syphilitic meningo-encephalitis are not diagnosed by me as multiple sclerosis, though I know that later, if I saw them, I would perhaps make this diagnosis.

Dr. Charles R. Ball, St. Paul: In the United States we have been slow to recognize the protean symptomatology of multiple sclerosis, and Dr. Crafts' paper has called our attention sharply to this fact. Multiple sclerosis has an extensive symptomatology which is often much different from the classical description given in most textbooks. We must get, in general, a broader conception of this disease and then we will find that it is not at all an uncommon affection.

Dr. D. I. Wolfstein, Cincinnati: We do not see as many well developed cases as are shown in European clinics, but we do see cases rather frequently in which the diagnosis is justified. Long ago attention was directed to the so-called cases of "formes frustes," and most of the suspicious cases fit into this designation. Often there is difficulty in distinguishing between this disease and hysteria, but if one keeps a sharp lookout for organic signs, such as a Babinski sign or mild clonus, or slight rigidity, the proper diagnosis may be made. I have a case now which shows a marked astereognosis of the affected hand, and this without other involvement of sensation. I wish Dr. Crafts would give his experience on this point of astereognosis. Are there any contributions to the treatment? Is there any value in the silver nitrate method? I have relied on thiosinamin sodium salicylate (fibrolysin) and sodium cacodylate.

Dr. G. A. Moleen, Denver: The abundance of literature is an index of our ignorance in regard to this disease. In Colorado I have seen a number of cases, but not in proportion to the number mentioned in this paper. It, like other conditions, has an apparent tendency to run in groups. There is one point which was omitted in the paper and that is the frequent mistaking of this condition for hysteria. Risien Russell says that in this condition we make many mistakes, and he was often forced to revise his diagnosis of hysteria. The characteristic striking remissions after very grave symptoms are misleading. This would suggest hysteria, but is, after all, a characteristic of this disease. The character of the disease would lead one to believe that it is constant in type. The eye symptoms mentioned by Kennedy I have never seen. I have seen attenuation of the vessels and glistening appearance of the nerves, with some degenerative patches. Kennedy has seen a number of cases in which there was papilledema. I have thought that the idea that there was some improvement with thyroid was justified. I have had improvement in one case endure for eighteen months on thyroid extract. The patient still shows a slight degree of spasticity in his gait.

Dr. B. Sachs, New York: I am sure that now we are recognizing disseminated sclerosis here as frequently as they do in Europe. The early stages must be considered suspicious. The disease is a protean one and the onset varies in many cases. I think that formerly cases were largely classed as chronic myelitis and spastic paraplegia. There is a diffuse myelitic disturbance. Seventy-five per cent. of these cases are early disseminated sclerosis. The absence of abdominal reflexes is a characteristic sign. I must differ with Dr. Moleen. We recognize pallor of half the disk as a symptom of disseminated sclerosis, and a nystagmus confirms this. Stammering is a rare symptom. Intention tremor is less frequent than absence of abdominal reflexes. We will have to improve our diagnostic ability in this particular. The cause of the disease is puzzling. I do not know whether it is hereditary or due to deficiency of glandular secretion (though I hesitate about that), or that there is a toxic origin of some kind, or some basis of deficient development. As for the treatment, we have found no specific. I find a large number of youthful spastic paraplegias that are really early cases of disseminated sclerosis. We can treat the spasticity by massage, baths and electricity. Perhaps we can use sodium cacodylate and push it to the extreme. The disease has remarkable remissions and exacerbations.

Dr. Frank R. Starkey, Detroit: I have in my care at present a patient with multiple sclerosis with a peculiar onset. The patient, 34 years of age, at the age of 17 became lame in the right leg and was unable to walk without assistance. She went home and rested for an hour, the lameness disappeared and she went to a dance and danced. After three or four weeks the trouble returned in the right knee, particularly; there was, however, no pain. At first the condition would clear up after rest and return with fatigue. The condition grew gradually worse and she was confined to her room for weeks. She took osteopathic treatments and obtained relief. She married, and within ten days the lameness returned and affected both legs and the right arm and she is, at present, unable to stand or walk without assistance. From this description I concluded that the case was one of hysteria and was therefore greatly surprised on examining her to find that she was extremely spastic in both legs, the right arm and both hands. She had increased reflexes, including ankle clonus and the Babinski reflex. There was no intention tremor or scanning speech. There was, however, a slight nystagmus and absence of the abdominal reflexes. I took one of my colleagues to see her who made a diagnosis of lateral sclerosis, which was also made by others. I, however, believe the case to be one of disseminated sclerosis. She gave a distinct history of abscesses of the roots of the teeth at the time of the onset and more or less trouble of this kind since, and at present has a number of old roots in her mouth. I believe there is a definite relation between the tooth trouble and her nervous phenomena. The picture at the beginning, however, was that of hysteria, and now the signs of lateral sclerosis predominate.

Dr. Andrew H. Woods, Canton, China: It has been repeatedly pointed out during the past ten years that syphilis of the cerebrospinal system produces, at times, multiple, millet-sized sclerotic lesions which are in some cases with difficulty distinguished microscopically from the lesions of "disseminated sclerosis." The accompanying meningomyelitis in syphilitic disease is an important diagnostic point. There is, however, no reason to consider the syphilitic virus as the cause of "disseminated sclerosis." The distribution of the sclerotic lesions, both in these cases of syphilis and in ordinary "disseminated sclerosis," points to the blood lymph system as the avenue of approach of the causative agent. It almost certainly does not enter through the pia. The appearance of the pia-arachnoid in syphilitic cases is consistent with what we would expect from its protective function. The sections show round-cell infiltration, often intense. Inflammation may spread by contiguity to a thin segment immediately behind the membrane. The arterioles that enter the cord from the arteries of the pia are interfered with. The whole appearance is that the pia is keeping the irritant away from the underlying nervous tissues. The function of the cerebrospinal membranes and fluids is not nutritive. It is mechanical—lubricant and protective. The fluid is a hydraulic buffer for the cord which is suspended in it. The pia is not meant to absorb and transfer substance into the cord, but it is a barrier to keep things out. Hence, if organisms are acting within the tracts and gray matter of the cord and brain, we would antecedently expect that chemical agents injected into the intramembranous space would fail to penetrate the cord and act on those organisms.

Dr. E. D. Fisher, New York: The subject of the frequency of multiple sclerosis was taken up in the New York Neurological Society some years ago, and the number of cases reported was very small. After that, as Dr. Sachs said, we began to study the symptoms more carefully and found more cases, but I think that then some cases were included which were not multiple sclerosis. The differential diagnosis between multiple sclerosis and hysteria is often difficult to make. Many apparently hysterial cases turn out to be multiple sclerosis. In London, in 1913, at the International Congress, many cases were presented at the Hospital for Paralytics and Epileptics. I think it was asserted that it was one of the most common diseases of the nervous system. As to the etiology, it may be of toxic origin, a disseminated myelitis. This differs from a primary degenerative disease. When we come to examine conditions in the cord and brain we find degeneration, but the peculiar characteristic of the primary disease is that the degeneration does not descend, as in myelitis. Where we have a localized sclerosis it is permanent and there is no such thing as a cure. No treatment will affect the sclerosed tissue and no new formation is possible, so far as we know. All that we can do is to alleviate some of the symptoms. I should not place my diagnosis on any two symptoms. It is a general picture and cannot be diagnosed by one or two signs. The prognosis is unfavorable and the disease is incurable.

Dr. L. M. Crafts, Minneapolis: I think there is as much multiple sclerorsis in Pittsburgh as in any other city. Dr. Sachs says it is as fully recognized now in the United States as abroad. If he means by the United States, New York, possibly so. I was asked by Dr. Bramell why our observers were not reporting more multiple sclerosis. In Europe it is considered the most common form of organic nervous disease. It is a matter of closer observation. It is well not to make a diagnosis on one symptom alone, but with two characteristic symptoms, one referring to the cord and the other to the brain, one can make a diagnosis. In reference to the differential diagnosis from hysteria, that is at times difficult. One case I considered hysteria until I found Babinski's sign, which is never found in hysteria. One speaker mentioned astereognosis. I had two or three cases with astereognosis. In regard to the teeth and tonsils, there were a number of my patients with this coincidence. I had one case resembling amyotrophic sclerosis in a man of 69 who got out of his buggy after a long drive and found he could not walk. Dr. Fisher spoke of it as myelitis; it is agliosis. For treatment I have used thiosinamin sodium salicylate (fibrolysin), and there have been distinct remissions; but these may occur spontaneously. The case must be watched for long periods of time. The neurologist is the one who should be consulted. I think the Charcot picture should be revised. Scanning speech is not typical. There are many variations as typical as the Charcot type.

The First Infant Welfare Work.—In France, about twenty years ago, 1892, Dr. Budin stated a movement of paramount importance for France—I may say, for the world. He observed that physicians took care of the mother, but let the infant child take care of itself. The result was an infant mortality so great that between a man of 90 and a child of 1 day, the chance of living one week was in favor of the man of 90. In many parts of the country, out of two children, one was sure to die; in the more thickly populated industrial quarters in certain cities out of three children, two were sure to die. Dr. Budin thought it was necessary first to learn and secondly to teach; thus he came to establish his "Consultations for Nurslings," which have done wonders. Mothers come with their babies every week. The children are examined and the mothers are instructed how to rear their offspring to strong, healthy men and women, and produce citizens to enjoy a useful life. He especially taught that children were meant to be nursed by their own mothers, and that the use of the best cow's milk or of a most scientifically prepared mixture could not compare with the mother's milk.—*Jules Jusserand. Some Checks to Infant Mortality. Trans. American Association for Study and Prevention of Infant Mortality. First Annual Meeting, 1910, p. 34.*

NOTES ON THE STANDARDIZATION AND ADMINISTRATION OF ANTIMENINGOCOCCIC SERUM *

HAROLD L. AMOSS, M.D.
NEW YORK

Now that wide and repeated experience here and abroad with reliable preparations of the antimeningococcic serum in the treatment of epidemic meningitis has resulted in a consensus of opinion favorable to its value, it is time to take up seriously the question of providing federal standardization in order that the public may be protected from poor and worthless preparations.

Unfortunately, as the distressing English experience of 1915, later retrieved when supplies of potent serum became available, showed, the commercial producer of the serum cannot be left to determine his own method of manufacture and his own standard of potency.

There has been misconception also as to the practicability of standardization, which needs to be removed by a statement of the essential facts of the case.

Undoubtedly, our minds have been clouded and our action impeded by the notion, which is only slowly giving way, that the only therapeutically active serums are those which are antitoxic in the strict sense, while the other class of antibacterial serums stands on an insecure therapeutic foundation. In the face of the convincing data available relative to the effects of the antimeningococcic serum and the growing favorable testimony to the value of the antipneumococcic serum Type I, this prejudice is being overcome.

The essential obstacle in each case—that of the antimeningococcic and antipneumococcic serum — arises from the circumstance that neither the meningococcus nor the pneumococcus is a consistent species, both being separable into more or less distinct type groups. As regards the pneumococcus, the practical case is simple and the whole matter of standardization is reducible to a formula, since up to the present the serum Type I alone is therapeutically effective, and no serum should be accepted as up to the standard which does not contain given quantities of antibodies for Type I pneumococcus.

While the case is not quite so simple for the meningococcus, it is by no means so complex as to defy ready solution. In one respect, the therapeutic possibilities of the antimeningococcic serum are far wider than serums for pneumococcus, since it can be made effective against all the meningococci causing epidemic meningitis.

Fortunately for our purpose, 80 per cent. or more of all the cases of epidemic meningitis are caused by two type strains or groups of the meningococcus, regular or normal and parameningococcus, and nearly the remaining 20 per cent. by two more strains not quite so definitely marked off biologically as the former or intermediate meningococcus A and B.[1] Hence, a potent serum may be prepared with, say, the four type cultures, which, if of sufficient titer, may be accepted as standard.

---

* From the Laboratories of the Rockefeller Institute for Medical Research.

[1] A comparative study might readily reveal that the four type groups here given correspond with the so-called Types I, II, III and IV of the English classification.

Any one familiar with the recent invaluable English experience which has been collected into a pamphlet issued by the British Medical Research Committee[2] will know that, by pursuing a course similar to the one just outlined, they have insured supplies of an efficient preparation of the antimeningococcic serum, whereas formerly, without this control, they were grievously disappointed in the action of the available product.

This procedure will, as stated, yield a valuable and reliable preparation. In following it, there is nothing to prevent a more conscientious or ambitious manufacturer improving further his particular brand of serum by adding to the selected type cultures examples of the variants from the types which are occasionally encountered. This practice should indeed be encouraged; but it should not permit any clouding of the essential issue, which is to produce a highly potent serum for the standard cultures of meningococcus.

It is my intention to define what would be a readily realizable and adequate standard of potency. But before doing this, I wish to describe a series of tests which were carried out very recently with commercial samples of the antimeningococcic serum and, coincidently, with three other samples prepared by departments of health and the Rockefeller Institute.

TESTS OF COMMERCIAL SERUMS

Several immunity reactions have been employed in testing the value of therapeutic serums. When applied to the antimeningococcic serum, they arrange themselves in the following order of specificity: (1) agglutination at 55 C.; (2) opsonization; (3) complement fixation; (4) anti-infectious power, and (5) antitoxic power. Gradually, agglutination of the type cultures of the meningococcus is displacing other and less indicative methods of standardization. Accurate clinical experience also is confirming this decision. We have made a series of observations, which extend now over two years, on the relation of agglutination to the therapeutic efficiency of the serum. Thus, we have tested the meningococci isolated from the cerebrospinal fluid against several so-called polyvalent samples of the serum; and we have noted that when the sample of serum failed to influence the course of the disease, agglutinating power was either absent or very low. Moreover, we have also noted that the replacement of the impotent preparation of serum with one carrying agglutinins for the culture in question would, as a rule, control the infection. A serum of proper standard should agglutinate the four type cultures mentioned in dilutions of from 1:400 to 1:1,000. The still more efficient serum may show agglutination for all the variants in dilution of from 1:200 to 1:500.

Five samples of antimeningococcic serum produced by the larger producers of biologic products were purchased in the open market. The dates for return on all the samples were 1918. Presumably, therefore, they were recent products. To them were added three other samples: two had been obtained not long before from departments of health, and the third was a recent sample of the Rockefeller Institute preparation. They were examined for physical properties and for agglutination against four type cultures. The results are given in the accompanying table. The dilutions of the serum were set up by letters so that

[2] Bacteriological Studies in the Pathology and Preventive Control of Cerebrospinal Fever Among the Forces During 1915 and 1916, Special Report Series, No. 3, National Health Insurance, Medical Research Committee, London, 1917.

the worker carrying out the agglutination tests was not aware of the origin of the several samples.

Moreover, the physical properties of certain samples were such as to make their employment by intraspinal injection, to say the least, dangerous. To explain this point, the accompanying illustration was made.

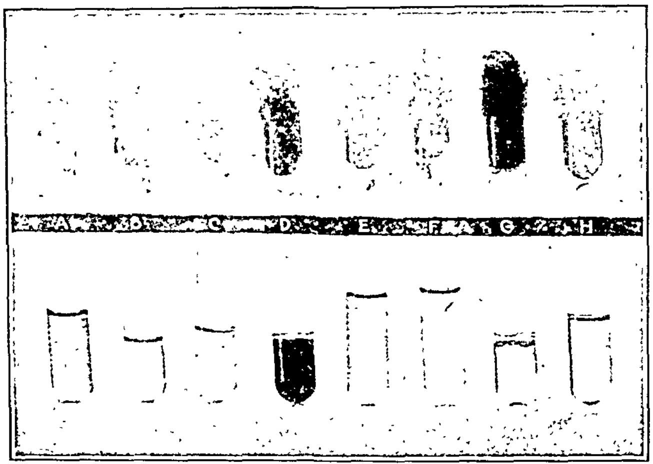
SUMMARY OF THE RESULTS OF THE TEST

Serum A (commercial) is slightly active against normal or regular culture No. 10 and sufficiently active against the parameningococcus culture No. 60. In other words, it is not sufficiently representative of the different type cultures to be suitable for therapeutic purposes. Moreover, the sample, while transparent, contains hemoglobin in excess and in an amount giving a red color to the serum. Severe reactions would follow its administration.

Serum B (board of health). The agglutinins are somewhat developed for the regular or normal meningococcus Nos. 1 and 7, well developed for the two irregular cultures Nos. 10 and 30, and for the parameningococcus. It is a useful product, but could be improved by the employment for immunization of larger quantities of the regular meningococcus cultures.

Serum C (commercial). Agglutinins are present in doubtful or small amounts for the regular meningococcus Nos. 1 and 7, and in somewhat larger quantity for the irregular culture No. 10 and the parameningococcus. This serum, which fulfils the requirements in physical condition, is of uniformly low titer and improperly balanced in type agglutinins. Its therapeutic efficiency is dubious.

Serum D (commercial). The physical properties of this sample (as shown in the illustration) condemn it wholly. It consists of a dark, opaque, rather heavy liquid, which did not clarify on centrifugalization for twenty minutes at 3,500 speed. The preparation would undoubtedly give rise to severe, possibly to dangerous, reaction. And yet the product is marketed in dark amber glass so that the physician would not detect the color and suspect the danger. In order to be fair, it should be stated that another sample obtained directly from the New York office of the firm was straw colored and clear; but there is no excuse for putting out the former preparation. Had the container been clear glass, the sample would have been rejected; hence until clear white glass is used, it is advisable to pour out or inject about 1 c.c. of the serum into a test tube or other receptacle before administering it. Moreover, the agglutinins are present in low quantity except for irregular type culture No. 10. Aside from the physical properties of the one specimen, the preparation is unsatisfactory for therapeutic purposes.



Specimens of antimeningococcic serums illustrating variations in the physical condition of commercial products.

Serum E (commercial). Agglutinins are present in adequate quantity for irregular culture No. 10 and for the parameningococcus culture. The quantity present for the regular meningococcus is minimal. The preparation is unsatisfactory for therapeutic purposes.

Serum F (commercial) represents the regular meningococcus and parameningococcus and the two irregular type cultures, but is improperly balanced. Taken as a whole, its agglutination titer is too long.

Serum G (Rockefeller Institute) represents adequately all the type cultures. A balanced serum which should fulfil therapeutic expectations.

Serum H (board of health) is a satisfactory product that should be therapeutically active.

COMMENT

A critical examination of the results of the tests exhibited in the table brings out points both interesting and practically of high importance.

The first thing that impresses one is the striking inferiority of the commercial as compared with the noncommercial products. There would appear to be very little excuse for this discrepancy. It is particularly true of the antimeningococcic serum that it is unsafe to reduce its preparation to mere routine. Second bleedings without further injections of cultures should not be made, and in no instance should the horses be bled for serum until a test bleeding has shown that agglutinins are present in adequate amount for the principal type cultures. The practice of mixing samples of serums of high and low titer to increase the volume collectable should never be practiced.

There is nothing involved in the preparation of a satisfactory serum that cannot be mastered in a properly organized commercial laboratory. But knowledge of the subject, conscientiousness and vigilance are demanded to obtain a product that will fulfil reasonable standard conditions and be therapeutically effective. It is to be trusted that merely by pointing out present deficiencies, rectification will be made; and it may also be hoped that the constituted federal authorities will establish and enforce a standard which is readily attainable and secure.

There is one point of technical interest in the table. Comparison of the agglutinability of regular or normal cultures Nos. 1 and 3 shows that one is more readily agglutinable than the other. This is a familiar phenomenon and one recognized in respect to many bacterial species. Its practical import in this connection is to the effect that in controlling the agglutination titer, reliance is not to be placed merely on a highly agglutinable culture.

There is no difficulty involved in this procedure, since it will practically never happen, and indeed it should not be permitted to conduct the immunization with a single regular or a single parameningococcus culture. Several of each, together with the representatives of the intermediate types, should properly be employed for injection.

It will be sufficient and a great gain to have progressed so far. As already indicated, a still more perfect serum product can be turned out by paying constant attention to the rarer variants and introducing them into the scheme of immunization, controlling their effects also by agglutination tests. But this refinement is one not to be introduced into the plan of standardization.

STANDARDIZATION

The next question relates to a practical standard for the serum. It should include two requirements. The first should define the physical qualities of the product which are acceptable. This definition should

Any one familiar with the recent invaluable English experience which has been collected into a pamphlet issued by the British Medical Research Committee[2] will know that, by pursuing a course similar to the one just outlined, they have insured supplies of an efficient preparation of the antimeningococcic serum, whereas formerly, without this control, they were grievously disappointed in the action of the available product.

This procedure will, as stated, yield a valuable and reliable preparation. In following it, there is nothing to prevent a more conscientious or ambitious manufacturer improving further his particular brand of serum by adding to the selected type cultures examples of the variants from the types which are occasionally encountered. This practice should indeed be encouraged; but it should not permit any clouding of the essential issue, which is to produce a highly potent serum for the standard cultures of meningococcus.

It is my intention to define what would be a readily realizable and adequate standard of potency. But before doing this, I wish to describe a series of tests which were carried out very recently with commercial samples of the antimeningococcic serum and, coincidently, with three other samples prepared by departments of health and the Rockefeller Institute.

2. Bacteriological Studies in the Pathology and Preventive Control of Cerebrospinal Fever Among the Forces During 1915 and 1916, Special Report Series, No. 3, National Health Insurance, Medical Research Committee, London, 1917.

But Hans Bode[1] wisely remarks, "It is very important that the eye shall rest on a substantial support and that the oral and nasal cavities shall be separated from one another."

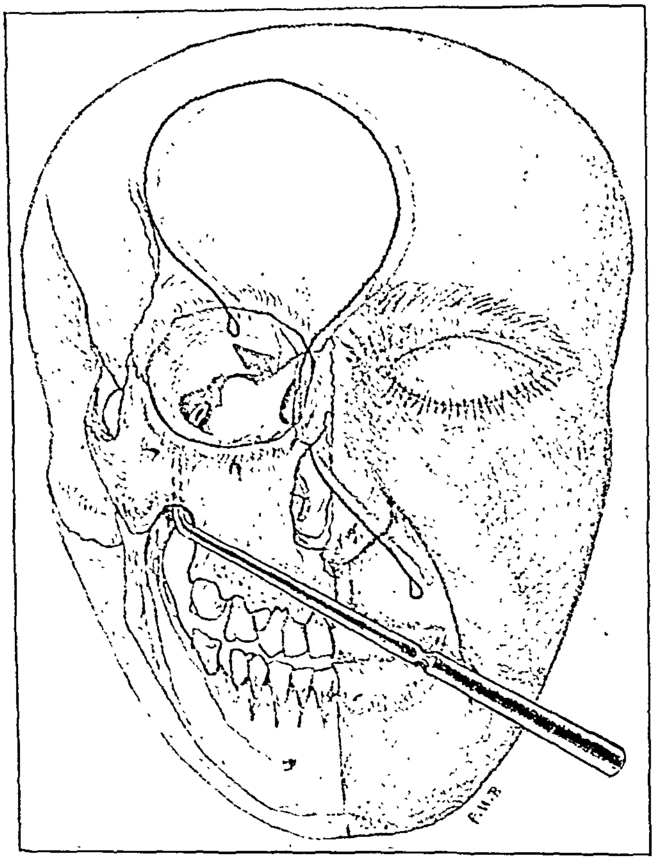

Fig. 2.—The saw carried across the orbit to make its exit through the sphenomaxillary tissue into the zygomatic fossa.

As early as 1859, Langenbeck preserved the periosteum of the orbit, and Bode tells us that his literary studies reveal the fact that Heine, Jacobs, Israel, Peyrat, Jallaguier, Koenig and Kuester have operated in this way. Koenig, Jr.,[2] in 1900, provided support for the eye by splitting from the outer part of the temporal muscle a flap one and a half finger-breadths long which contained the coronoid process and the anterior edge of the submaxillary border, together with the muscle insertions. This substantial flap he applied below the globe in order to supply a firm base of resistance where the bone had been removed. Riese obtained a good result with the method.

Another ingenious substitute for the lost support was provided by Schoenstaedt,[3] who used the transplanted middle turbinate as a flap.

Bode remarks that, since most of the operations of resection of the superior maxilla are undertaken for the extirpation of malignant growths, it is frequently not feasible to leave the periosteum. With this statement I am entirely in harmony. Kuhn,[4] who worked with the advice of Rehn and who used the material of the latter's clinic, strongly recommends more radical operations than have been, as a rule, performed.

I have been appalled, when first viewing the cavity left after resection, at the inroads made by malignant disease in the structures contiguous to the part removed. But I can substantiate the statements of Kuhn that much can be done to prevent recurrence by extensive removal of invaded tissues about the base of the skull, the soft palate and the neighboring accessory cavities.

It is with the conflicting necessities in mind—on the one hand that the globe shall be substantially supported, and on the other hand that the malignant disease shall be thoroughly extirpated—that this paper is presented. Yet it is to be remembered that there are not a few cases of superior maxillary cancer which begin at points remote from the orbit, and that some resections are made for nonmalignant disease.

Since the floor of the orbit is very thin and the lower border of the orbit is not massive, the retention of this tissue may frequently be practicable with the aid of the method to be presently described.

Curiously enough, but few advances have been made in the actual technic of these resections in many years. Kuhn's[5] anesthesia by tracheal tubage and preliminary ligation of the external carotid artery are most desirable advances in management.

There are many incisions from which to choose in laying bare the structures to be removed. Any incision through the soft parts may be used. I prefer the one which vertically divides the upper lip in the median line, passes around the ala of the nose, runs then toward the inner canthus of the eye, and, before reaching that point, curves along the lower orbital edge to the end rather far out toward or on the malar bone. This flap is first turned out and held wrapped in gauze. The hard [illegible] soft palates are divided in

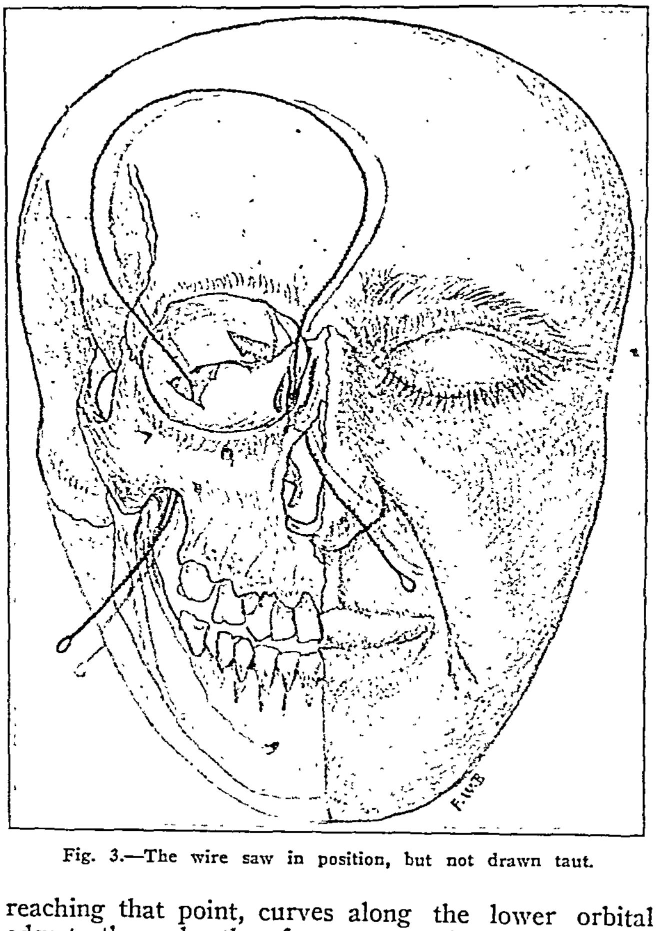

Fig. 3.—The wire saw in position, but not drawn taut.

the usual way, with the chisel or with the Gigli saw.

Then the separation of the floor and the margin of the orbit from the body of the bone is effected as follows:

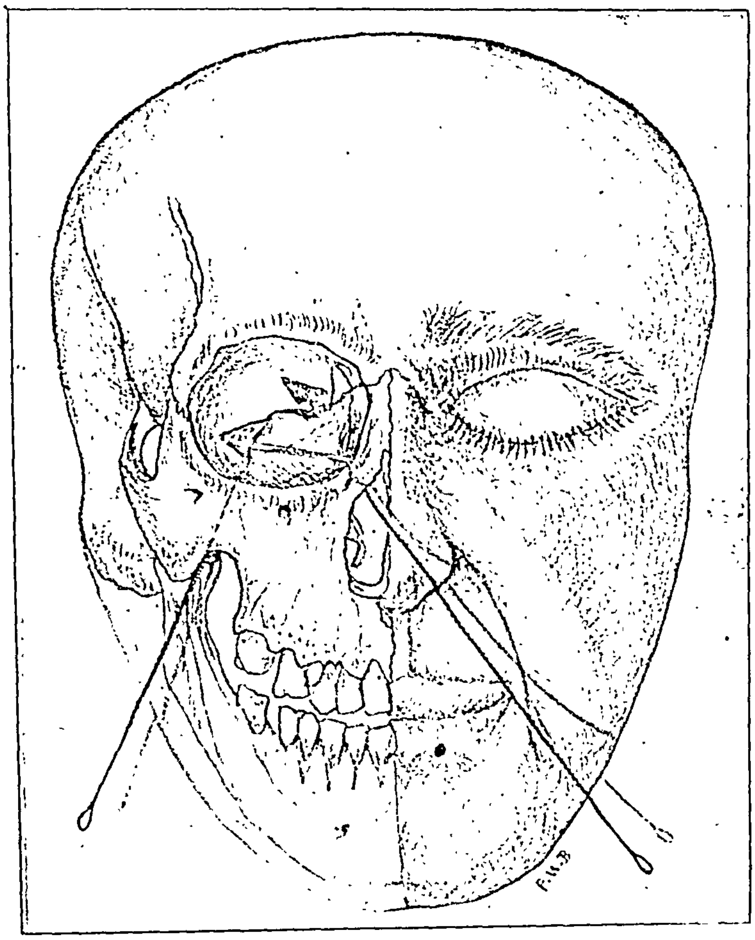

Fig. 4.—The approximate line of the saw-cut.

With a spatulous retractor, the contents of the orbit, including the periosteum, are held up, after the soft parts have been separated carefully from the bony edge and floor of the orbit. Now an ordinary grooved director is bent into a large hook and passed into the orbital cavity. With its point the anterior part of the sphenomaxillary fissure is found and the point is passed out into the zygomatic fossa, where it can be first felt by the finger-tip and then caught in a heavy silk loop. Withdrawal of the instrument brings with it the loop by the aid of which the end of a light, and therefore easily flexible, Gigli saw is carried through.

Next the grooved director is passed from within the orbit toward the median side, to the lacrimal groove and, with slight pressure, caused to perforate the thin bone and enter the nasal cavity. By being pushed further on, its point may be made to emerge around the bony margin of the nasal cavity. There it is again grasped by a loop of heavy silk, which is withdrawn as before through the wound below the globe. This loop of silk, removed from the grooved director, grasps the loop of the Gigli saw and carries it across the floor of the orbit and out through the nose.

This gives us a wire saw passing under the malar bone to the anterior part of the sphenomaxillary fissure, thence traversing the cavity of the orbit to the lacrimal groove, entering the nose through a perforation of the shell-like bone and emerging from the bony nasal framework.

The operator is now to attach the handles of the saw, and make his cut with the usual precautions of keeping the saw at work as nearly in a straight line as possible, and making the excursion of the handles as great as he can, in order to diminish to the utmost the danger of breaking the saw.

It will be seen that this maneuver accomplishes at once three of the classical steps of the operation: It divides the malar bone, separates the superior maxilla from its orbital connections, and transects the nasal process of the upper-jaw bone.

The remainder of the operation is conducted in the way described in the textbooks of surgery.

The drawings, made by Dr. F. W. Beilstein, show the steps of the maneuver in reverse order.

I have had one opportunity to carry out this procedure in the case of a man, aged 75, suffering from carcinoma of the superior maxilla, the disease beginning in the antrum of Highmore just above the left canine tooth. After preliminary extirpation of the regional glands in the neck and ligation of the external carotid artery, the usual flap was made and the procedure which has been described was carried out.

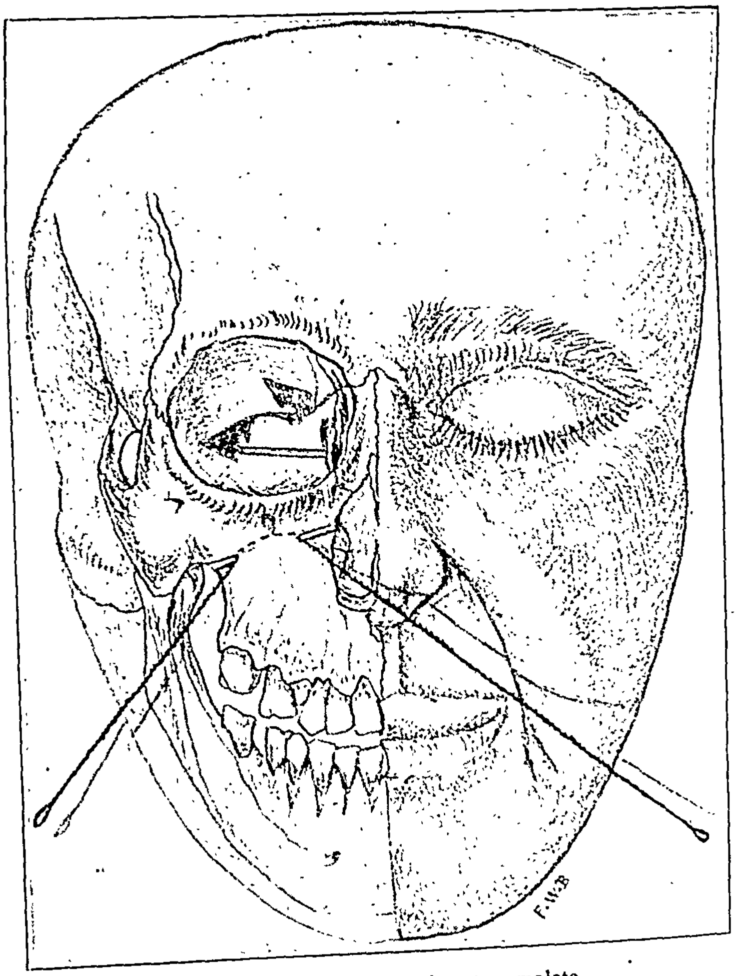

Fig. 5.—The saw-cut almost complete.

This experience taught that the grooved director chosen should be large and easily bent to any curve, and that the silk should be braided and very heavy to avoid breaking. No difficulty was experienced in raising the contents of the orbit and working beneath them. Sharp bleeding occurred when instrumentation was carried out through the nose. But this ceased spontaneously after a few minutes. The total amount of blood lost was not great. With the greatest regret it must be recorded that the patient died on the table before the sutures had been applied, but after the extirpation had been completed. The pulse continued beating at the wrist long after respiration had ceased, making it evident that ether poisoning was the cause of death. The feasibility and practicability of the operation were proved.

I recommend this modification of the usual procedure, when the floor of the orbit has not been invaded by disease, in order that the globe of the eye shall retain its full support, that the palpebral muscles shall have their attachments unimpaired, and that the disfigurement of the face by collapse shall be maintained at the minimum of necessity.

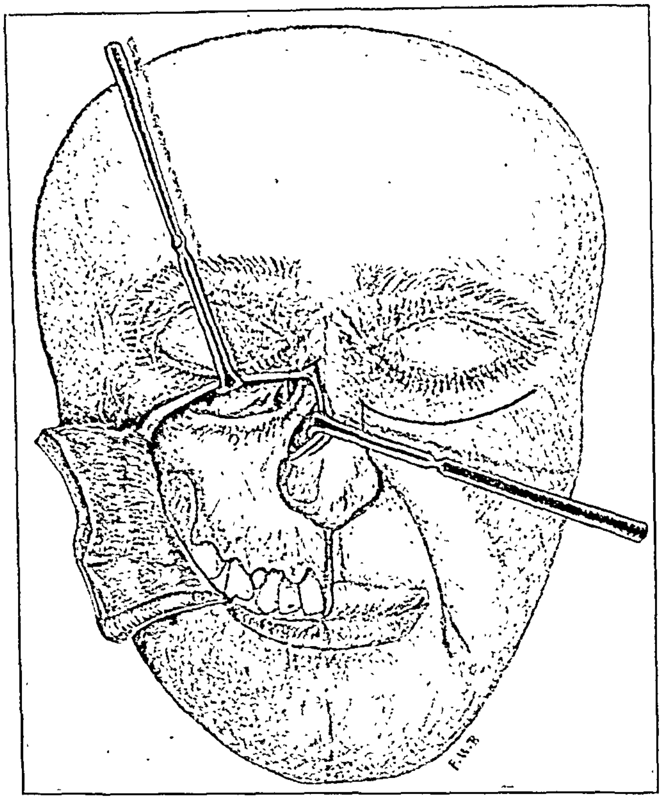

Fig. 6.—The exposure of the orbital floor and the entrance to the nose.

31 North State Street.

FRACTURES *

H. R. ALLEN, M.D.

INDIANAPOLIS

In presenting this paper I cannot include all fractures, nor all of the details of any one fracture. I have selected certain conventional methods usually employed in every day practice, and I shall attempt to show that those methods are defective, and with each defect I shall submit my reasons for calling them defective, in each incident supplying what I consider a correction of the defective method. In other words, I believe there are sound logical reasons that explain bad results in treating fractures, and I also believe that better and more consistent results will follow better methods. The better methods, at least, are logical, they are consistent with the unalterable laws of nature, and they are approved by physicists and mechanical engineers.

By directing my first attack on the popular use of the weight and pulley in treating broken femurs, I shall bring to light the absurdity involved in at least one conventional method. However, if any one can defend this traditional usage, we shall all be glad to hear from him.

Back in the dark ages and probably before that time, and at the present time, bone setters searched for a consistent force to hold broken bones in a constant normal position. Hence they selected the constant force of gravity, knowing that bones would unite in the position in which they were held. They did not stop to consider that they were using the force of gravity, first, on the patient's body, where it acted as a fixation force, and secondly, on his leg, where it acted as an active kinetic force to oppose the most varied of all opposing influences which are to be found in the varied and irregular contractions of muscle tissue. Muscle tissue, if prodded with a sharp piece of bone, may exhibit spastic contractions, a tremor, relaxation or irregular contractions, all of which are to be opposed and balanced between the active force of gravity applied through the weight and pulley, and the fixation force of gravity applied to the body of the patient as it holds him down on his bed.

It is a difficult matter to convince any physicist that there is any balance or constancy in a formula that uses gravity as a fixation force on one end, and the active and acting force of gravity on the other end, while between the two there is present the unconstant and varying opposition of muscle contractures. Hence, in defending the use of the weight and pulley, I propose not to drift into a dissertation on the wonderful results following its employment, but rather to adhere to the fixed basic mechanical principle involved. Those wonderful results obtained can be logically explained and obtained without the weight and pulley. What we are really striving for is the hope of putting our specialty on an unassailable basis, at least from a mechanical point of view, and I desire to see eliminated all possible guesswork and bunglesome misuse of mechanical principles in this age of sound mechanics. If I am wrong in the hope or in my mechanical claims, we should all know it.

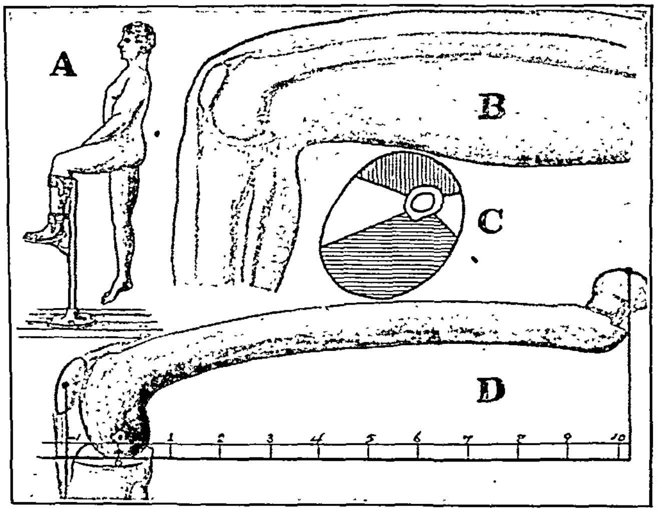

Fig. 1.—Mechanical principles involved in correcting a fracture of the femur: *A*, the powerful leverage of the femur in lifting the body; *B*, thigh muscles which cause direct traction; *C*, cross-section of the thigh illustrating groups of muscles concerned in reducing fracture of femur; *D*, the femur pictured as a scale beam.

---

* Read before the Section on Orthopedic Surgery at the Sixty-Eighth Annual Session of the American Medical Association, New York, June, 1917.

* Because of lack of space, this article is abbreviated in The Journal. The complete article appears in the Transactions of the Section and in the author's reprints. A copy of the latter will be sent by the author on receipt of a stamped addressed envelope.

Believing that there is no constancy, balance or logic in the principle of the weight and pulley, I will, before suggesting some substitute, take up one more absurd item in regard to the amount of the weight used with the pulley.

Figure 1 *A* represents a young man with his leg fastened securely to an iron frame. Without unusual effort he lifts the entire weight of his body directly from the floor. Suppose he weighs 225 or 250 pounds; then, while lifted clear of the floor, the only part of his body not lifted by the extensor muscle would be his leg and foot which rest on the steel frames. In other words, the rectus muscle through the agency of the femur as a lever is lifting a total of 200 pounds.

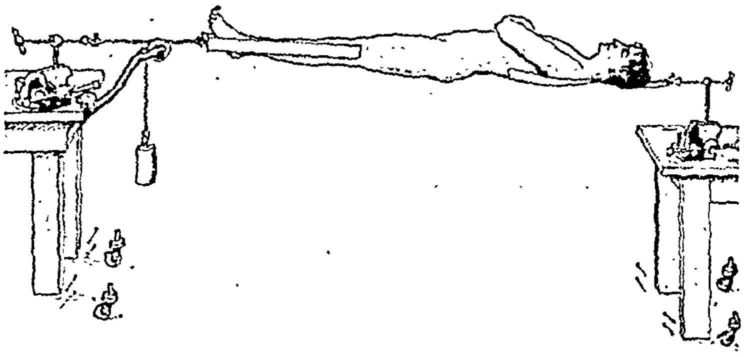

Fig. 3.—The mechanical difference between fixation energy and the weight and pulley. Fixation of support is secured by nailing the two tables to the floor instead of having them mobile on the casters, and thus the patient's body may be fixed as desired.

Figure 1 *D* represents the femur laid off as a scale beam; — 1 represents the length beyond the fulcrum *O*, while more than 10 units extend back to the long arm of the lever. Thus when he lifts his body, 10 × 200 pounds represents the strain or traction of the rectus muscle. I believe no one could tolerate the traction of 1 ton during the time of bone union.

In Figure 1 *C* it will be noted that the cross-section of the thigh at point *B* represents the total amount of the thigh muscles capable of making direct traction. The total traction released for activity in the event of a fractured femur would amount to several tons. It will be observed that the segment in the cross-section indicated by vertical lines represents the rectus. The lateral unstriated segments plus the lower, laterally striated segments exceed the rectus by five or six to one. This being the case, what special or particular function would a 10, or 50, or 100 pound weight perform in the event that the patient sneezed or contracted his thigh muscles, or during a spasmodic contraction while sleeping or dreaming? We all know that some muscles tire out and others never seem to offer much resistance. We also know the spastic type of muscles that resist, such as a finger in writers' cramp.

If the formula or principle of the weight and pulley is wrong, and if the weight is insignificant, then it behooves us to employ correct mechanical principles. The idea is constant normal position. We must use fixation energy for fixation purposes.

Figure 3 represents the mechanical difference between fixation energy and the weight and pulley. The weight and pulley would allow the body of the patient to sag. The same is true if the traction screws were employed, provided the two tables were mounted on rollers. But, if fixation energy should be applied (by first nailing the tables in place on the floor), then the traction screws would drag the patient's body to a straight horizontal line like a tight rope, if such unpardonable traction were used. By placing the patient in bed the traction screws merely guarantee a fixed distance between themselves, any part of which fixed distance may be occupied by the patient. If steel pins above and below the fracture are held at a fixed distance apart, they serve as fixation energy. A Lane plate serves as fixation energy. If the square ends of bone rest against each other, or if the bony spicules and their retaining notches rest against each other, there is fixation energy. But, if the patient disturbs such contact by using the bed pan, or by coughing or other commotion, then the bones are apt to be displaced and must be reduced to opposing position again. It is easy to understand how a good result might be obtained with the projecting spicules and notches of bone, even if a trifling weight was or was not employed. If the projecting spicules of bones caught and hung in muscle tissue, a fair result might occur in spite of a trifling weight and pulley.

In regard to the reduction of the shaft of the femur, there are cases in which screw traction will draw the fragments down past each other and permit the ragged ends of bone to come into their proper places. There are other cases, and plenty of them, in which the hamstrings and gastrocnemius and soleus muscles prevent reduction, provided the knee joint is extended.

Figure 4 *A* represents the knee flexed and relaxed, while *B* represents the knee extended with the posterior muscles tense. Any one who will extend the knee joint will find the hamstrings tight. They will surely be loose if the knee joint is flexed. Now the so-called transverse fractures are not like the sawed edges of a bone. If they were, the bones would go into place with the knee extended. But the transverse fracture is transverse roughly with bony spicules and notches left. Hence, in order to get the bones in line, the muscles must provide the requisite length for the rough areas to pass each other. But if the muscles are tight, when the knee is extended, they will not stretch enough to permit the rough ends to pass each other; consequently, the thigh must be muscularly unlocked by flexing the knee. Under knee flexion the bones easily go into place and, in these cases, will lock in place if the knee joint is again extended. This

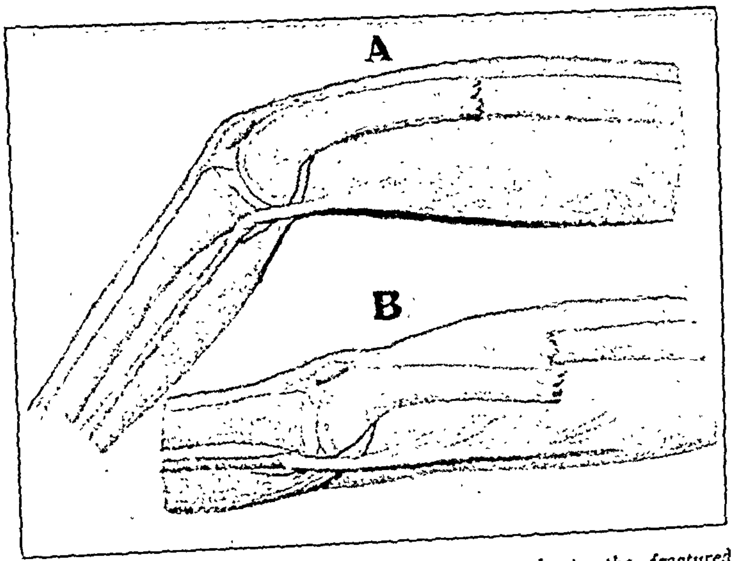

Fig. 4.—Unlocking the thigh so as to approximate the fractured ends: *A*, the knee joint flexed and muscles relaxed with bone fragments in perfect apposition; *B*, the leg extended and the fragments displaced.

matter of unlocking the thigh is so helpful that it is strange it could have escaped mention in our textbooks.

There is another item involving the use or misuse of good mechanics that should be mentioned. In the treatment of hip joint disease and in manipulation of certain fractures and dislocations, a line of traction parallel with the neck of the femur is sought. It is regularly attempted, as shown in Figure 5 *E*. Adhesive plasters, *B B*, on the leg have traction applied to them, while a band, *A*, is passed around the thigh and is pulled laterally. The composite result of the traction on *A* and *B* is supposed to result in a downward and outward traction in line with or parallel to the neck of the femur pointing from the acetabulum to *C*. The actual result, however, is almost directly at right angles, as indicated by the arrow pointing toward *D*.

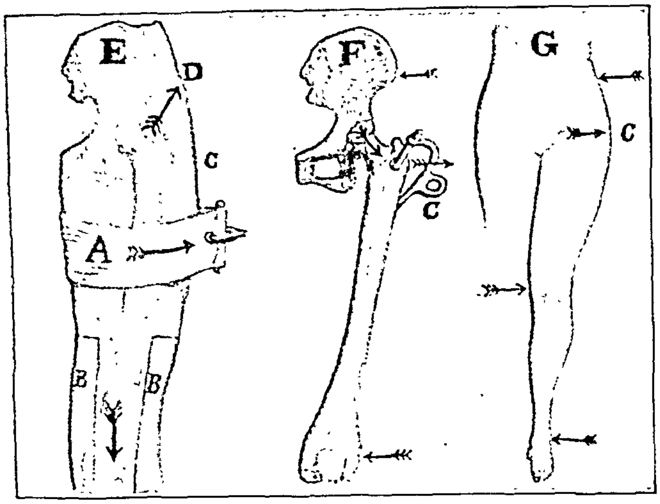

Fig. 5.—Traction to be applied in a line parallel with the neck of the femur: *A*, band applying lateral traction; *B*, adhesive strips making downward and outward traction in line with the neck of the femur pointing from the acetabulum to *C*; arrow pointing to *D*, actual result of such traction; *F*, proper position maintained by downward and lateral traction as indicated by arrows; *G*, points of pressure at which desired traction is secured.

The desired traction can be accomplished by following the unusual suggestion indicated in Figure 5 *F*, or to a limited degree by following the lines of pressure indicated by the arrows in *G*.

Figure 6 indicates one of the important triangles of the thigh in regard to which I wrote quite extensively twenty years ago. Two sides of the triangle are bone, while the third is muscle. If one side or one angle of a triangle is changed, the entire triangle is altered. Thus, if the side *A–C* is bent inward, the rest of the triangle must change. It does change, and as the femur is dislocated or fractured and free to move and the rest of the triangle is intact, the shaft or line *C–B* will travel upward or outward or in the two directions simultaneously.

Figure 7 is interesting in showing how a little pressure on the gracilis and adductors will become a tremendous upward pressure. If in *B* there is a 1,000 pound weight suspended by a rope, a very slight pressure at the middle of the rope will bend it, and if bent at all the weight has been lifted, although it may have been lifted only a fraction of an inch; yet it is true that 1,000 pounds has been lifted.

C represents the same state of affairs, except that the 1,000 pounds are secured to the top of a rod, while the rope is secured to the bottom of the rod. A pressure of a few pounds, or even a few ounces, against the middle of the rope will produce a pressure of a thousand pounds upward. This illustrates how we may create tremendous destructive pressure in the head of the femur and acetabulum by applying lateral pressure or traction to the gracilis or adductor muscles.

D represents, in all fairness, the increased pressure required to lift the same weight by applying more pressure or traction when the rope makes an angle of about 90 degrees. But the gracilis and the adductors make no such angle.

Figure 8 represents various positions employed in using the weight and pulley method.

In considering the basic mechanical principles appropriate to the treatment of fractured femurs, the ingenuity of the physician will be greatly improved if he does not consider this or that transverse or spiral or compound complicated fracture, but pictures constantly in his mind how he would treat a patient who had the middle third of the shaft entirely shattered and disconnected. By keeping this picture in mind, the physician will be stimulated to consider basic principles. If they are appropriate to a shattered femur they might be appropriate to a more simple form of fracture, since after all the thigh is merely an eccentric muscle tube with a bone filling its lumen. Of course a shattered or simple fracture of the neck of the femur are treated alike, as fractures of the neck of the femur are the easiest of all fractures to treat without deformity or shortness. The rules of fixation energy for fixation purposes are borne out here as elsewhere, and I know of no case of nonunion or "ligamentous union" which is genuinely nonunion to have resulted from this method of treatment at any age. In very old people of 80 or 90 years the bones unite. These patients may die with or without any treatment, but I believe their chances are better if no analgesic or any anesthetic is used at any time during the period between accident and recovery, and there is no occasion for using anesthesia or analgesics, as the treatment is not painful nor pain-inflicting, but is absolutely comforting from the moment it is begun. This, of course, is a statement to be substantiated by the physician's own patients when this method is adopted. The simplicity of the method is the feature most difficult of comprehension to the average practi-

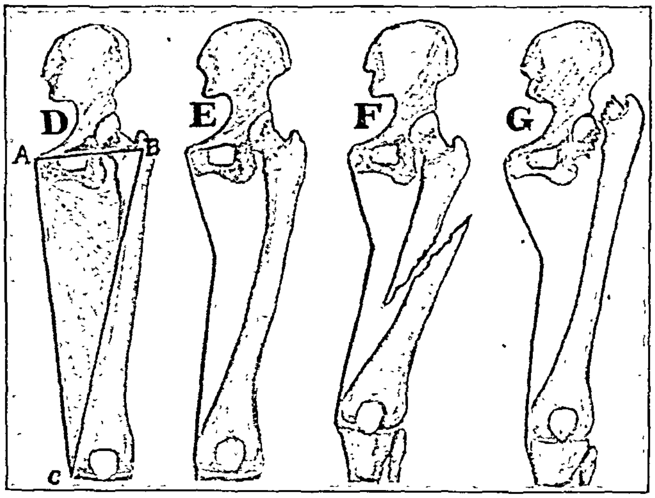

Fig. 6.—Triangles, two sides bone and one side muscle; if line *A-C* (muscle side) is altered, bone shaft *C-B* will travel upward or outward, as shown in *E*, *F* and *G*.

tioner who employs it. An ordinary army stretcher with a traction screw or strap at each end and a hole in the canvas for the bed pan service is a simple, direct and efficient fracture splint. But the details are trivial; the essential features are the selection of appropriate mechanical principles.

Allied to fractures of the femur are fractures of the humerus. Here the principle of fixation energy for fixation purposes is equally essential. Instead of using the tuberosity of the ischium as a superior fixation point, we use the muscles in front and behind the axillary space protecting the blood vessels and nerves from pressure. The inferior fixation area is the angle pad anterior to the elbow resting down on the forearm and back against the arm.

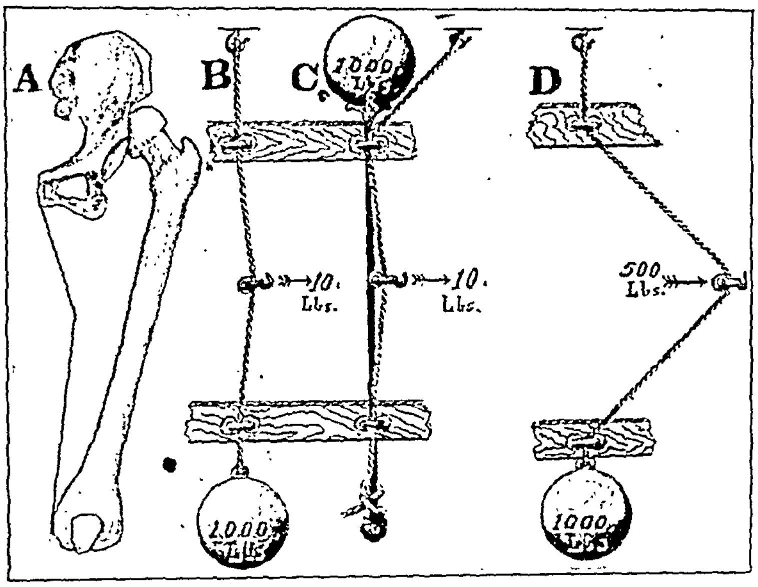

Fig. 7.—Illustrations of possible destructive pressure on the head of the femur and acetabulum by applying lateral pressure or traction to the gracilis or adductor muscles: *A*, displacement of the femoral head through improper traction or pressure; *B*, slight lateral traction in the center causing weight to rise; *C*, weight on top of rod raised by lateral traction; *D*, extreme traction required to lift the same weight to an angle of 90 degrees.

In Figure 9 a band under the wrist serves to hold the elbow in right angle position, affording a base for the angle pad. This type of splint is not new and untried, but has been in use by me for twenty-five years. The wire and adhesive plaster brace, as will be noted at *C*, is light, rigid and clean, permits free inspection at all times and is easily adjusted, is neither expensive nor difficult to construct, and is efficient in affording constant diastasis and maintaining constant normal length of humerus. The fixation area is supplied by the superior axillary base and the lower base on the forearm close to the arm as shown in Figure 9 *C*. Likewise, *B* represents the axillary sling, crutch or bandage showing the pectoralis muscles in front and the latissimus dorsi behind, against which the padded sling rests protecting the axillary blood vessels and nerves. *A* is a transverse section through the arm and chest showing that the padded axillary sling should not compress the blood vessels or nerves of the arm.

Figure 10 shows in series the construction of the angle or elbow pad. I have frequently made them out of empty ether cans. Have the nurse hold the can over a gas flame until the solder melts, quickly throw the can on the tile floor to prevent its resoldering itself, then cut and bend it, stick it together with adhesive plaster and pad it, and apply it with bandages that do not encompass the arm or forearm, but attach to the brace as shown in the drawing.

Fractures of both bones of the forearm seem to give considerable trouble for a variety of reasons. These bones are provided not only with muscles paralleling them capable of long axis compression, but also diagonal pronators and supinators, and one other not to be forgotten is the rotator. The last and universally overlooked condition is the fascia. The fascia is inelastic, built to fit over a forearm containing only two bones. If the bones are broken obliquely and override each other, the inelastic fascia is called on to provide space for three or four bones instead of two.

Figure 11 *A* represents normal cross-section of the forearm, showing the interosseus membrane in a straight line. *B* represents fractured bones overriding and taxing the inelastic fascia to its full capacity. The interosseus membrane no longer occupies a straight line position.

A frequently used method of treatment consists, first, of traction, and, second, the application of a padded separator to be crowded down between the bones, as shown at *F*. If the fascia is loose and flabby, this scheme might be feasible; but after fracture there is usually sufficient swelling to fill the fascia to its capacity. If already tense, then any pressure will draw the bones closer together instead of separating them. This is shown at *C* and *D*. It is a well known and established fact that a circle surrounds the greatest area of any geometric figure for a given fixed length of peripheral line. Consequently, if the circle is compressed at any point, the compression is equal for all parts and the compression is extended to the contents of the circle. Therefore the intervening separation pad becomes an interosseus approximator, and obviously should not be used.

The question of using fixation energy in this case becomes complicated. Some experienced operators use Lane plates, although Lane informs us that they are not as good for arms and forearms as they are for legs and thighs. I dare say many physicians have had good and bad results with them.

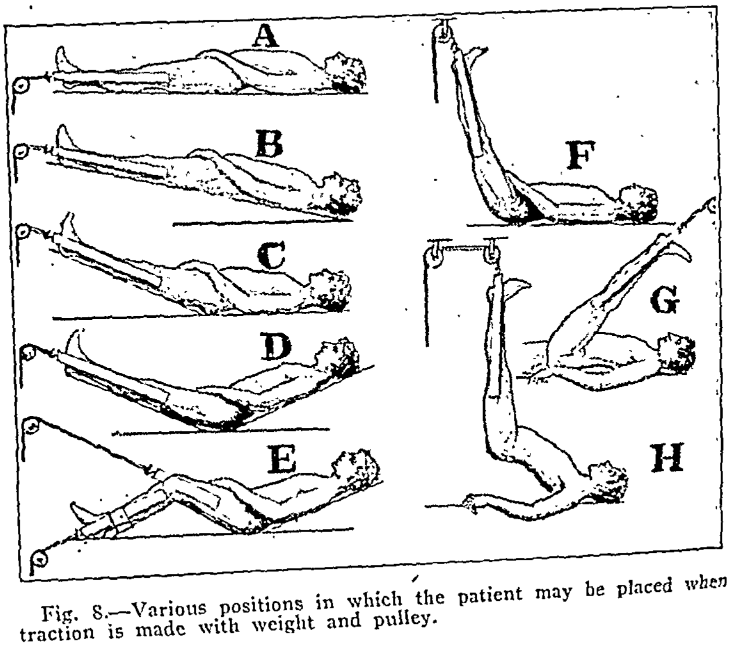

Fig. 8.—Various positions in which the patient may be placed when traction is made with weight and pulley.

Figure 12 shows a Lane plate installed. It will be noted that only one or two turns of thread are confined to the durable, hard shaft of the bone, while six or seven turns of the thread extend into the open space of the canal of the bone. Of course, no efficiency accompanies this unengaged portion of the screw. Furthermore, the round hole that fits so snugly the newly installed screw becomes oval or egg-shaped in a week or two, and then even the upper thread or two become as useless as those sticking down into the marrow or open canal.

Figure 13 represents the bone gimlet with its low melting alloy handle compared with the screw. It will be noted that the screw at best has only one-eighth to three-sixteenths inch bearing, while the pin goes clear through the bone, engaging both sides. Now the little round holes for the pins become just as oval as they do for the screws. The difference is that the pins transfix the entire forearm, and at all times provide external control over internal conditions. If the pins become loose, the slack can be taken up outside. It cannot be taken up with a Lane plate, but the plate can slough out while the pins remain in position. In the event that the Lane plates succeed in staying in, they remain in forever; but the pins are removed after bone union, and the forearm is not half human and half hardware. Another advantage of the pin is the long leverage obtained from passing from one side of the bone to the other. The strain is divided and the holes remain round longer. The details concerning lack of infection and freedom from pain have been covered in previous papers, although they are open for discussion at any time.

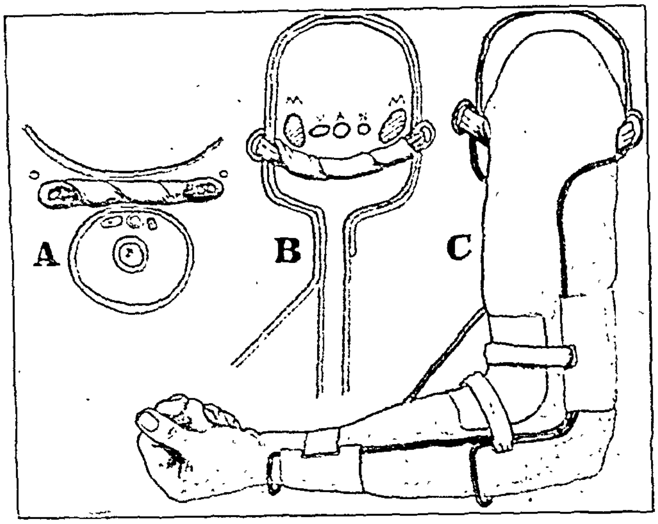

Fig. 9.—The principle of fixation energy as applied to fractures of the humerus: *A*, cross section of the arm illustrating the relationship of vessels and nerves to the humerus and showing the correct position of the axillary sling to prevent compression of the blood vessels, and nerves; *B*, relation of important structures to the padded axillary sling; *C*, axillary sling and wire brace applied so as to hold the humerus in the correct position.

The last fixation device that I shall take up is the wire stabilizer shown in Figure 14. In this diagram there are presented four or five technically different types of wire stabilizers attached internally to the broken bone and externally to the straight edge, which straight edge is usually made of the low melting alloy. In badly shattered bones these stabilizers and external straight edges are indispensable. I prefer the plain flat metal to the tube instruments. Sterilization is more certain and easier to accomplish. This device forms the simplest type of stabilizer.

CONCLUSIONS

I trust that I have been both fair and successful in presenting just a few of the many defects in treating fractures, and also successful in presenting efficient and unquestionably sound remedies for the methods I have referred to as inappropriate or deficient.

In the department of mechanical surgery, the surgeon's methods will be judged to some extent by their mechanical soundness. Consequently, fractures and dislocations and other cases involving mechanical problems will be referred to that department which is the most efficient and most capable of treating them. If it can be shown that we can best treat these patients, they will not be classed as general surgical cases.

1899 North Illinois Street.

ABSTRACT OF DISCUSSION

Dr. Jefferson D. Griffith, Kansas City, Mo.: Fractures of the long bones, especially the fractures of both bones of the forearm, are difficult to treat and get a perfect result. One may get a functional result with the bones overlapping, and a useful arm, but the thing is, How can we get a perfect result? We can all use this apparatus of Dr. Allen's. I think very well of it. The claim made of reducing and having an aseptic condition is all right.

Some years ago Dr. Parkhill of Denver employed the same principle, with screws and clamps which he connected afterward. They could be put on without any trouble at all with the patient under an anesthetic. I have used his device, and I could succeed in maintaining reduction very well with it after I got it on. But it required the use of his complete outfit, which you must have on hand before you commence reducing the fracture. After you have the pins through, by Dr. Allen's method, you have to use the fusion clamp to maintain the malleable metals in position. If this can be done easily, I like it. The Parkhill method was the same as that of Dr. Allen, except that it had the screws with it, with movable plates on both sides. I have his apparatus at home now and have used it in fractured femurs and forearms. I like Dr. Allen's method much better, I think, if I can find a way to get at it and do it easily.

Dr. Edwin W. Ryerson, Chicago: I should like to ask whether Dr. Allen has any difficulty with paralysis from the crutch under the arm in fractures of the humerus treated by his ingenious apparatus.

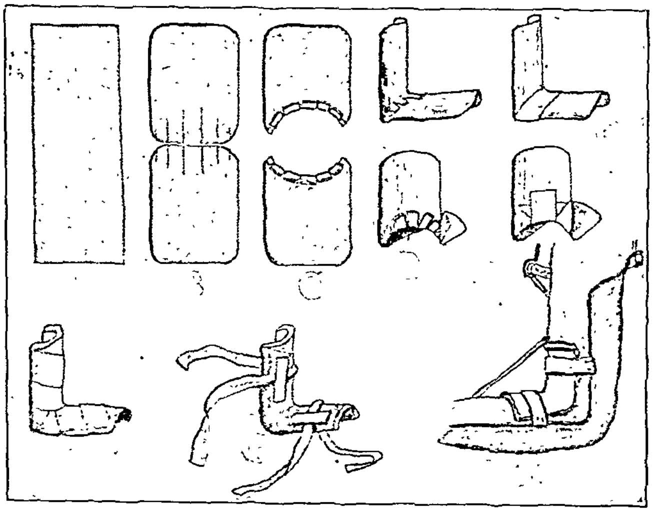

Fig. 10.—Method of construction of the angle, or elbow pad from an ether can: *A*, ether can flattened out; *B*, ends cut ready for bending; *C*, ends curved; *D*, ends approximated to form an angle; *E*, adhesive strips fasten ends together; *F*, the can padded; *G*, arm straps placed in position; *H*, the elbow support applied.

Dr. Joseph E. Root, Hartford, Conn.: I wish to emphasize the value of a constant fixation, instead of the old method of using a weight and pulley, which are inconstant. We have in Connecticut a celebrated family of Swedes who are natural bonesetters. The best representative of this family once made this remark, which has always stuck with me, and has been my guide in my entire work with bone: "Doctor, if you put on a variable extension,"—he referred to the ordinary

At every meeting I am asked for the formula of this alloy. It contains 50 per cent. lead, 25 per cent. tin, 12.5 per cent. cadmium and 12.5 per cent. bismuth. The wire loop stabilizers are not through and through devices. I have seen real pus accumulate about them and flow out over the skin without one degree of temperature rise. They are so constructed as to provide sufficient outlet from their base out.

I am very glad that Dr. Ryerson has called attention to the possibility of establishing crutch paralysis by using the splint for fractures of the humerus. Like any crutch made on the nonrigid straplike plan there is less danger of crutch paralysis than with the rigid type of crutch. But it must be remembered that any crutch paralysis also depends on a prolonged and a considerable degree of pressure which is never necessary in this system of treatment for the following reasons.

In the first place there is little or no traction necessary to hold broken bones in their proper place after they have once been pulled down to their proper place. For twenty-five years I have worked diligently on the application of mechanical principles to surgical procedures and I want above all else to have orthopedic surgery put on a sound dynamic basis, since it represents the mechanical division of all medicine and surgery and it should be unassailable in its very foundation. Not one has come out and attempted to discuss the basic principles I have come to present to you. There is not one who can logically account for the basic mechanical principles that he uses every day.

THE THERAPEUTIC VALUE OF ORAL RHYTHMIC INSUFFLATION OF OXYGEN

WITH DESCRIPTION OF A SIMPLE APPARATUS FOR ITS EXECUTION *

S. J. MELTZER, M.D., LL.D.
NEW YORK

The literature on the relation of oxygen to the processes of life, the rôle which oxygen plays in internal and external respiration, and the availability of that gas as a therapeutic measure, is immense. I shall not attempt to review it even in a cursory way, but it may not be amiss to discuss some of the problems of this subject, especially those which we encounter in recent medical literature. We may conveniently divide the discussion of our subject into two aspects: the physiologic and the therapeutic.

THE PHYSIOLOGIC ASPECT

It seems to be the dominant opinion among physiologists that inhalation of pure oxygen or air strongly enriched with oxygen is of no greater oxidative value to the normal organism than the inhalation of simple atmospheric air, which contains about 20 per cent. of oxygen. This view seems to be upheld by two considerations. In the first place, it is a fact that the oxygen in the blood is carried chiefly by the hemoglobin, which, it is generally assumed, is nearly saturated with oxygen and would not take up more of it even if the individual were breathing pure oxygen. The only part of the blood which may take up more oxygen when offered under higher pressure is the serum; but it seems to be generally accepted that the amount of oxygen which the serum is thus able to take up is a small and negligible quantity. The second influential consideration is the assumption, which seems now to be quite generally accepted, that the decision as to the amounts of oxygen which the organism is to absorb rests finally and exclusively with the body cells, that is, with their necessities, activities and storing capacities, and is not influenced by the oxygen pressure within the tissue lymph. In other words, oxidation, the chief process of life, depends on cell activity and not on the tension of oxygen within the blood or within the tissue lymph.

The question under discussion has been the subject of numerous investigations. Lavoisier and Seguin, as far back as 1789, were the first to draw the conclusion from their experiments that "there was no increase in the vital processes as the result of breathing pure oxygen." Probably the last, and surely one of the best and apparently most careful investigation, is the one that was published a few years ago in this country by Benedict and Higgins.[1] They say that a critical examination of the entire literature strongly favors the belief expressed by Lavoisier. But they say that "nevertheless we find that there is much that is lacking in the evidence thus far secured, so that the matter is not yet definitely settled." Their careful investigations, however, led them to a similar result, namely, that there is no difference in the gaseous metabolism between breathing ordinary air and breathing oxygen mixtures of 40, 60 or 90 per cent.

But even with regard to this careful research, Krogh[2] said: "It is extremely probable, however, that there is in these experiments a slight systematic error," and he comes to the conclusion that the "breathing of oxygen does increase the metabolism to some slight extent."

Apparently there are many factors of greater or lesser importance that have to be taken into consideration before we shall be justified in accepting as final any estimate of the extent of the influence that the inhalation of air with a higher partial pressure of oxygen may exert on the normal gaseous metabolism. The hemoglobin is even normally not completely saturated with oxygen, nor is the oxygen in solution in the blood serum normally an entirely negligible quantity, and it is certainly not negligible during an increase of the partial pressure of oxygen of the inhaled air.

There is no real quantitative analysis of the amount of oxygen present in the tissue fluid. The analysis of the various body secretions does not mean the same as an analysis of the tissue fluid. There are some authoritative investigators who still believe in the storage of oxygen, intramolecularly or extramolecularly, in loose chemical combination or in physical solution. There are other considerations to be solved; but I shall not attempt to discuss any of these points. However, I wish to call attention to one factor which has not yet been taken properly into account, or at least not from the proper point of view, as it seems to me, and that is that element in biology which I designated, a decade ago, as the factor of safety.

All experiments under consideration start implicitly from the point of view that the oxygen content in the air is the physiologic amount sufficient for the maintenance of the life of the animal under normal conditions. But is this entire amount also indispensable? It has been established by many experiments that the

[2] Krogh, August: The Respiratory Exchange in Animals and Man, London, Longmans, Green & Co., 1911.

organism remains in a normal condition even if the partial pressure of the oxygen in the air amounts to only 12 or 13 per cent. What is the significance of the considerable surplus of oxygen that the animal is normally breathing? From my point of view it presents a factor of safety in the function of respiration, a factor which I have shown to exist in most of the functions of the animal body.[3] I shall not attempt to discuss again this problem in its details. But it will not be amiss to give an example taken from every day life which will suffice to illustrate the meaning of the underlying principle of the factors of safety and the simplicity of its requirements. Let us take, for instance, two houses of about the same size, of which we have good reasons to expect that each house uses up the same amount of coal in a given time. But while the occupant of one house, who may possess larger means and a greater foresight, lays in a larger supply of coal, let us say, twenty tons at a time, we find the occupant of the other house, perhaps because of lack of means or the necessary foresight, provides himself with only one ton of coal at a time. The difference in the fate between the occupants of the two houses becomes strikingly evident when unexpectedly necessities arise for greater consumption of coal, and when, furthermore, these necessities set in under circumstances of time and place that make coal difficult to obtain.

Life is characterized by the instability and variability of its states, and all its functions must therefore be so arranged as to be capable of being ready to meet the highest possible demands. The function of respiration has for its object chiefly the provision of the organism with oxygen, properly and safely. While, as far as the muscle system is concerned, the provision of the respiratory function with factors of safety is under normal conditions surely of a satisfactory extent, because, as we know, the muscle is capable of continuing its contractions even if the oxygen tension of its surrounding atmosphere is fairly low, it is different with the central nervous system. Here we know that a comparatively slight reduction in the oxygen tension interferes profoundly with the activities of this system. Are we justified in assuming that the addition of 7 or 8 per cent. of oxygen is just the limit of the factors of safety which the respiratory function may need and use under all conditions? Furthermore, in breathing normal atmospheric air, what is the fate of the 7 or 8 per cent. of oxygen present in the normal air above the amount actually indispensable for maintenance of life? Is this oxygen stored away somewhere and in some manner, to be ready for immediate use when needed, or is it normally unabsorbed and got rid of in the same manner as is assumed to be the case when 20 or 30 per cent. of oxygen is artificially added to the atmospheric air?

THE THERAPEUTIC ASPECT

The extensive experiments on which the prevailing view has been founded, namely, that the addition of oxygen to the atmospheric air does not affect the normal metabolism, were made on normal resting individuals. But the processes of life, even in the normal individual, and even while at rest, cannot be represented by a straight line. The processes vary continuously within certain limits; that is life. These variations in the demands have to be met by variations in the supplies which have to be ready in store to the extent corresponding to the maximum limits of the demands of normal life. The 7 or 8 per cent. surplus of oxygen in the atmospheric air is apparently sufficient to meet the maximum demands of the respiratory function of the normal individual when at rest. But would it be sufficient to cover the demands when the individual is engaged in hard work? We know that unusual physical effort leads to shortness of breath, to dyspnea. Could this not be remedied by adding oxygen to the atmospheric air which the hard-working person has to respire? This is indeed the case, a fact which has been discovered and established by Leonard Hill[4] and his co-workers. Hill and Flack[4] found that inhalation of oxygen makes running up and down stairs easier, can be accomplished in a shorter time, relieves the feeling of dyspnea, and restores strikingly the vigor after fatigue from boxing, etc. They believe that the fatigue which follows an athletic feat is cardiac in origin and due to want of oxygen. Haldane,[5] whose great merits in the elucidation of the physiologic relations of carbon dioxid to the function of respiration are well known, was inclined to explain Hill's observation as a result of the deep breathing which is apt to occur in persons to whom oxygen is administered. Haldane's view was later refuted by new experiments, carried out by Hill and Mackenzie,[6] which brought new evidence that the favorable effects that they have obtained were indeed due to the inhalation of oxygen.

From the observations of Hill we learn that the addition of oxygen to atmospheric air exerts a favorable influence under conditions of greater bodily activities. Is inhalation of air enriched by oxygen also capable of exerting a favorable influence when the body is in a condition of rest but is undergoing pathologic processes? In other words, is there any evidence that inhalation of oxygen is capable of exerting a therapeutic effect? This question concerns a wider field than I intend to cover in this paper. There is no doubt now as to the therapeutic value of inhalation of air-oxygen mixtures in cases of poisoning by gases that affect the normal condition of the hemoglobin. But I wish to confine my remarks to the use of oxygen in certain types of diseases. Here we encounter a very unsatisfactory situation. On one hand, hardly a patient, sick with a respiratory or cardiac disease, will be permitted by the physician in attendance to die without trying oxygen inhalation. On the other hand, not many practitioners will readily admit that oxygen is doing much good in these cases.

Two factors are at the bottom of the skeptical attitude of physicians toward the value of oxygen as a therapeutic agent. In the first place, many clinicians are influenced by the view entertained by the great majority of physiologists that the addition of oxygen to the inhaled air is incapable of exerting a physiologic influence, that it does not affect the metabolism, and that the added oxygen returns unabsorbed. Furthermore, many clinicians and pharmacologists are still under the influence of the teaching that there is no fundamental difference between physiologic and pathologic processes. In this connection, the present attitude of the physiologist Haldane is very instructive.

[6] Hill and Mackenzie: Jour. Physiol., 1909-1910, **39**, Proc. Physiol. Soc., **33**.

As stated above, Haldane doubted that the favorable influence which, according to Hill, the administration of oxygen exerts on the work of athletes is due to oxygen. Very recently, however, Haldane[7] came out strongly for the administration of oxygen in inflammatory conditions of the lungs. He says:

> It may be argued that such measures as the administration of oxygen are at the best only palliative and of no use, since they do not remove the cause of the pathological conditions. As a physiologist, I cannot for a moment agree with this reasoning. The living body is no machine, but constantly tending to maintain or to revert to the normal, and the respite afforded by such measures as the temporary administration of oxygen is not wasted, but utilized for recuperation.

The second, and probably the more influential factor, is the actual fact that practitioners rarely see any favorable effect that may have been brought about by the administration of oxygen. But the general conclusion drawn from this fact, namely, that the inhalation of oxygen is incapable of exerting a favorable influence in pathologic conditions, is unjustifiable. The failure to see such an influence is probably due essentially to the inefficient method of administration. In most instances oxygen is given in a weak current through a funnel which is kept an inch or more from the mouth of the patient. Under these conditions we can hardly speak of "inhalation of oxygen." The atmospheric air which the patient actually inhales is probably not richer by more than 2 per cent. of oxygen, if by so much. On the other hand, the funnel may be instrumental in making the inspired air richer in carbon dioxid and surely makes the air over the face warmer, an unpleasant sensation to the patient, who prefers to be fanned and cooled off. Therefore, we often see the patient pushing the funnel away or turning the head away from it.

THE AUTHOR'S APPARATUS AND EXPERIENCE IN THE USE OF IT

My personal experience dates back about two years. I was called up one night by a very unhappy mother who told me that her only son was dying and begged me to come over. The athletic young man of 25 years was sick with pneumonia, Type II. I arrived at about 2 a. m. and found several physicians around the patient, who was unconscious and deeply cyanotic. Respiration was rapid and very shallow. He had no corneal reflex and there was a thready pulse of about 190 per minute. The patient was apparently dying and the physicians expected death to take place within the next ten or fifteen minutes. Nurses were administering oxygen in the usual manner, that is, through a paper funnel, kept at some distance, the gas bubbling through a wash bottle at a moderate pace. I disconnected the rubber tube from the foot bellows of my pharyngeal insufflation apparatus[8] that I brought along with me, and connected it with an oxygen cylinder. I then inserted the pharyngeal tube in the mouth (not in the pharynx), turned on the oxygen and started working the respiratory valve. Within a short time after the beginning of the oxygen insufflation in the new manner, the cyanosis disappeared and the face of the patient became actually pink. Several minutes after the discontinuance of the insufflation, the cyanosis began to reappear gradually. In the course of the next five hours the experiment was repeated numerous times and invariably with the same result, that is, the cyanosis disappeared promptly during the insufflation of oxygen and reappeared several minutes after cessation of the insufflation. There was no perceptibly favorable influence on the other symptoms of the patient, except perhaps on the pulse. In the morning hours it came down to 180 per minute and was perhaps slightly fuller. At any rate, in the bedside parlance, it could be honestly stated that "the patient was holding his own." The waste of the gas was considerable. A tank of oxygen was used up in a short time. About 7:30 in the morning the supply of oxygen of the neighboring drug stores became exhausted, and it took some time before another tank of oxygen could be procured. Five minutes after the last insufflation had to be discontinued the heart stopped suddenly. The resumption of the insufflation of oxygen about ten minutes later had no effect whatever.

This patient was not saved; but nobody could have expected it when beginning treatment at that terminal stage. His life, however, seemed to have been prolonged, and it is impossible to state how much longer death would have been deferred, if the supply of oxygen had not given out. But this is an insignificant issue compared with the fact that the insufflation exerted an unmistakable effect on the profound cyanosis. Cyanosis, of whatever origin and nature, is a sure evidence that the respiratory function is profoundly disturbed. In the present case the cyanosis promptly disappeared on the administration of oxygen by the new method. Although we are dealing with only one case, each instance in this case in which the cyanosis disappeared on the insufflation of oxygen and reappeared on stopping the insufflation presents a complete experiment, an experiment that we were able to repeat at will. We made more than a dozen such experiments, and the results were invariably the same. These experiments permit at least the provisional conclusion that the insufflation of oxygen by the method employed in this case affects favorably the function of respiration when it is pathologically profoundly disturbed.

In the case here mentioned the apparatus employed was provisionally arranged and applied in great haste without consideration for the great waste of oxygen and other shortcomings. After observing the results, which seemed to be very encouraging, I devised a special apparatus for our purpose which is simple, inexpensive and works very satisfactorily.

The thick walled rubber tubing that is connected with an oxygen tank terminates in a strong rubber bag which, at its distal end, is connected with the proximal end of the respiratory valve.[9] The distal end of the last named device is connected by means of a short piece of rubber tubing with a flat metal tube which we may designate as a "hollow tongue depressor." If the ring of the respiratory valve is kept in the inspiratory position (right side), when the oxygen is turned on, the gas streams through the tube into the bag and from there escapes through the respiratory valve and the tongue depressor. If the ring is kept in the inspiratory position (left side) the oxygen cannot pass through the respiratory valve, and accumulates within the bag. The accompanying illustration shows the last mentioned position.

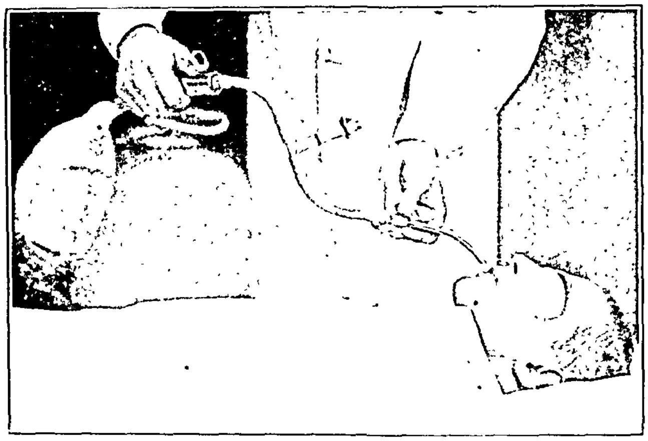
A., May 11, 1912, p. 1413; Simple Devices for Effective Artificial Respiration in Emergencies, ibid., May 10, 1913, p. 1407.

[9] A description of this device is contained in the Medical Record, New York, July 7, 1917.

The tongue depressor should be inserted in the mouth not much farther than the middle of the tongue, so that, if the patient is conscious, the presence of the depressor may cause no gagging or other discomforts. The lips should be kept closed. The ring should be moved from left to right and from right to left (a respiratory circle) about twelve times per minute. The oxygen should be turned on slowly, and the velocity of its escape should be controlled, so that it does not cause an overdistention of the bag during the expiratory pause. The turning of the ring to the right should be done slowly, so that the inspiration may develop gradually; the turning to the left is preferably done abruptly. The expiratory air escapes during the closure of the valve through the nose and through the aperture that appears above the closed valve when the ring occupies an expiratory position. It is advisable to time the inspiratory insufflation synchronously with the inspirations of the patient. However, I found that after a while the respiratory phases of the patient become involuntarily adapted to the phases of the insufflation.

I have tested on myself the action of insufflation of oxygen by means of this apparatus. When the insufflation is carried on under moderate pressure, there are no unpleasant sensations whatever. When it is done under too much pressure, the surplus of oxygen escapes through the nose and never enters the esophagus; but it causes some unpleasant sensations which conscious patients will probably not be willing to stand for any length of time.

My chest was examined by auscultation while I was receiving oxygen insufflation. It was found that each insufflation produced a distinct inspiratory blowing sound which was distinctly recognized even while I was holding my breath. It seemed, further, that the oxygen was capable of entering my lungs even when I was endeavoring to keep the glottis in a state of adduction. Some other objective and subjective effects of the insufflation experiments on myself will be mentioned later.



The oral insufflation apparatus. The rubber tubing which is connected with an oxygen tank terminates at its distal end in a strong rubber bag which in turn is connected with the "respiratory valve." The ring of this device occupies in this illustration an expiratory position; hence the distention of the bag. Above the ring an aperture can be seen, which appears only when the valve is closed (expiratory position). The respiratory valve is connected at its distal end by means of a short piece of rubber tubing with the hollow "tongue depressor." The T tube is here unessential.

The results of the observations made by the method of auscultation induced me to make a few experiments on animals. In deeply anesthetized cats, with the thorax split transversely, the insufflation by means of the apparatus was sufficient to distend the lungs moderately with each insufflation, even when the "tongue depressor" was inserted in the mouth, as in the human being, not farther than the middle of the tongue. It appeared, however, that when the tongue depressor was kept at that position, life could not be kept up indefinitely. When the tongue depressor was inserted in the pharynx, the oxygen entered readily the gastro-intestinal canal, which had to be prevented by keeping the abdomen compressed. With this precaution the artificial respiration was excellent and the animals remained in good condition. But in this arrangement the method is identical with the method of intrapharyngeal insufflation that I have described elsewhere, and is not applicable to conscious patients.

Dr. A. L. Meyer of our laboratory performed on himself a couple of experiments with the apparatus. After having been insufflated for about eight minutes, he analyzed his expiratory air at the end of the insufflations and found it to consist of nearly pure oxygen. The nitrogen of the atmospheric air was displaced by the oxygen.

The foregoing observations demonstrate that by using the "apparatus for oral insufflation of oxygen" under moderate pressure, oxygen undoubtedly enters the lungs, assists in distending them during inspiration, and displaces largely the nitrogen of the "dead space." The assistance that it renders to the inspiration ought to be of special value when the respiration of the patient is very shallow. The rhythmic character of the insufflation is, on the other hand, of value, as it does away with the resistance which the pressure of the continuous insufflation undoubtedly offers to the expiration, especially when, owing to the low vitality of the patient, the expiratory efforts fail to get succor from the activity of the expiratory muscles. Haldane administers the oxygen by means of a mask. The interruption of the continuous stream of oxygen in his method depends on the force of the expiration, which is expected to close a mica valve and, at the same time, prevents the entrance of the expiratory air into the bag that stores up the oxygen. I developed my simple apparatus about eighteen months previous to the appearance of the communication of Haldane. I then gave up the use of the mask even in my pharyngeal apparatus, mainly because it is liable to drive some deleterious material that may be present in the nasal and the postnasal cavities into the trachea and the lungs, there causing an infectious inflammation. Hill and Mackenzie[6] stated that in giving oxygen during athletic work they did not use the mask, because it increases the dead space. In dealing with sick persons some other points must be regarded as more important. Either the patient is already unconscious, in which case the respiration will be shallow and the expiratory force will be insufficient to close the valves and overcome the pressure within the bag. Or the patient is still conscious and he will surely feel the face piece, which fits over mouth and nose and is kept in position by an elastic strap, as a great inconvenience, and will not tolerate it. Haldane says he had but few opportunities to give his method a practical trial, but he reports that in a case of valvular disease he has seen the cyanosis "clear up at once on the administration of oxygen." There is some other difference between Haldane's method and mine. By Haldane's arrangement the oxygen is accumulated in a bag of thin vulcanized rubber. This oxygen enters, then, through mouth and nose, under comparatively low pressure, and it was not established whether the stream enters the lungs with any force capable of causing any degree of artificial inspiration. The bag in our apparatus, on the other hand, has thick walls and drives out the oxygen under a pressure which is sufficient, as we have previously shown, to cause a deeper inspiration and as a consequence also a stronger expiration. Haldane says that he knows from experiments on himself and others that the immediate effect of suddenly giving an abundance of oxygen may sometimes be unpleasant. I have taken oxygen many times by means of my apparatus, and sometimes as long as eighty minutes, and never felt any unpleasantness from it. Under stronger pressure and prolonged insufflation there might arise a sensation of dryness. This can be easily remedied by interpolating between the oxygen tank and the bag a wash bottle containing a Ringer solution. I agree, however, with Haldane that the oxygen should be turned on slowly.

Not being any longer in private and hospital practice, I am not in the favorable situation to have many opportunities for testing personally the value of the method. I am, nevertheless, in a position to report encouraging and instructive results obtained in a few cases, three of which were observed at the Rockefeller Hospital. I have to thank Dr. Chickering for the details in these cases. The first case was a most gratifying one. One forenoon in November, 1916, Dr. Cole, the director of the hospital, telephoned to our laboratory asking me to come over and administer oxygen with my apparatus to a pneumonia patient. To my reply that I would be over in half an hour, as I had to finish an experiment, Dr. Cole remarked that in all probability it would then be too late. I went over immediately and started the administration of oxygen by means of the oral insufflation. That patient recovered. Concerning the details of that case I shall quote Dr. Chickering.

REPORT OF CASES

Case 1.—The patient came in on the second day of his disease having signs of consolidation of both lower lobes of the lungs. . . . A Type II pneumococcus was recovered from the sputum. . . . He was treated with ethyl-hydrocuprein (optochin) on the third day of his disease, and this treatment was continued during the fourth, fifth, sixth and seventh days . . . partly by mouth and partly intramuscularly. On the fourth day of his disease the patient appeared extremely ill, temperature being 103.4 F., pulse 152, and respiration 40. He was delirious, color was ashy gray, lips and finger tips very cyanotic and tracheal râles were marked. At 10:45 a. m. the patient was given oxygen according to Dr. Meltzer's method intermittently for about two hours. While the oxygen was being given, his color changed surprisingly; his lips and ears lost their cyanotic color and took on a pinkish tint, and his general condition seemed decidedly improved. The following morning the patient's temperature and pulse were lower, 100.5 F., pulse 104 and the respirations 32. His temperature gradually came down by lysis to normal on the twelfth day of his disease. Convalescence was uninterrupted, no complications developing except a moderate amount of sterile pleural effusion which gradually cleared up without aspiration.

Case 2.—The patient was admitted, Feb. 19, 1917, and the oxygen treatment was begun on the twelfth day of the disease, one hour before death, February 28. The patient received ethyl-hydrocuprein treatment every day from the fourth day of his disease to the twelfth, the day of his death. On the day of his death, his blood culture contained innumerable colonies of pneumococci of Type II. "On the afternoon of his death his color suddenly changed . . . and severe cyanosis developed." Oxygen treatment was started. "While the oxygen was being administered, patient's cyanosis became less intense, but as soon as the oxygen was stopped cyanosis rapidly returned."

Case 3.—The patient was admitted to the hospital, Feb. 25, 1917, on the first day of the disease. "The next morning the whole right chest was involved posteriorly, and on the following day signs appeared anteriorly. At the same time the left chest became filled with fine moist râles. From the sputum an atypical Type II pneumococcus was obtained. Blood culture was sterile, blood count 29,000. . . . On the fourth day of the disease the signs became more marked for the left lower lobe; the temperature rose to 104.5 F. and the pulse to 140. The patient became pale and cyanotic. The extremities were cold and expirations labored and moist. Ethylhydrocuprein was begun at 2 p. m., and oxygen at 3 p. m.[10] . . . During the afternoon the pulse rate gradually increased to 142 (8 p. m.). The semicomatose, delirious condition deepened into unconsciousness about 7 p. m. From then on, the color could be maintained with oxygen, but the pulse quality became poorer; respirations increased from 44 to 60, and the patient's throat gradually filled with mucus. There was dulness over the left lower lobe, with râles throughout the left chest. From 2 a. m. to 6 a. m., the time of death, it was necessary to use oxygen continually in order to maintain respiration. If the oxygen was stopped for a few minutes respiration became more shallow and slow, and a dull blue flush appeared on face. This immediately disappeared with more oxygen. Gradually her color and respiration failed in spite of continual oxygen and the pulse, which was good almost to the end, became more feeble and gradually less rapid, until it failed entirely at 6 a. m."

COMMENT

In these three cases the pneumonia was due to pneumococcus of Type II, for which an efficient antiserum has not yet been developed. In all three cases the oxygen treatment was instituted very late, when the condition of the patient already appeared to be quite hopeless. Nevertheless in all three cases the oxygen insufflation manifested the tendency to exert a favorable influence. Even in the second case, in which the oxygen treatment began only one hour before death, the cyanosis of the patient became less intense while the oxygen was administered, to return rapidly when the oxygen was discontinued. This favorable effect on the cyanosis was still more striking in the other two cases, in which each short series of insufflations produced a change of color which outlasted the insufflation by shorter or longer periods. In the first case the face had a leaden, ashy gray color which is characteristic for oxygen deficiency.[11] This color disappeared quite soon after I started the insufflation, and the face gradually assumed rather a pinkish appearance. When I first saw the patient I understood why Dr. Cole thought that the administration of oxygen after half an hour might prove to be too late. I had little hope that the administration of oxygen would save the life of the patient. He was unconscious, had no corneal or lid reflex, the pulse was rapid, small, with very little tension, and the tracheal râles had the death sound. Nevertheless, that patient recovered. The third patient, who received oxygen insufflation for about fifteen hours, died; the pneumonia in this case was very extensive; it spread over both lungs. But here again, besides the pronounced action on the cyanosis, there seems no doubt that the oxygen insufflation prolonged the patient's life. We may be, in fact, we ought to be, optimistic enough to assume that in conjunction with the use of some other efficient or even only semiefficient remedies, early insufflation of oxygen may offer a chance even to patients of this type.

---

[10] In the first few hours the oxygen was administered without expiratory interruptions.

[11] Haldane: Brit. Med. Jour., Feb. 10, 1917.

The third patient has taught another favorable lesson, namely, that the oral insufflation of oxygen may assist in maintaining respiration. In the last few hours of her life, when the insufflation was stopped, the respiration became shallow and slow, and a dull blue flush appeared on her face which disappeared as soon as the oral insufflation was begun again. It acted apparently like artificial respiration. This fact reminds me of the statements previously made with reference to the auscultation of my chest while receiving oral insufflation, and to the behavior of the lungs in animals under the same condition.

I shall record further observations made by Dr. Victor Meltzer on a woman, aged 60, with marked arteriosclerosis and hypertension. For the last two years she was most of the time subject to cardiac dyspnea and had frequent and severe attacks of pulmonary edema. In the last two months of her life, oxygen was administered to her by means of the apparatus for oral insufflation during the attacks of dyspnea as well as those of pulmonary edema. It proved to be of great value, and afforded the patient great relief. When administered at the beginning of an attack of edema, not infrequently it prevented its full development. Among the most noticeable effects were the rapid disappearance of cyanosis.

Before concluding, I shall record briefly two observations made on myself. For experimental purposes I had oxygen administered to me several times by means of oral insufflation for periods lasting between thirty and eighty minutes. Objectively I can state that the insufflation brought high color into my face, which was noticed by persons who did not know of my experiment, and which did not leave me for several hours. Subjectively I found that it removed the sensation of fatigue and that I felt stimulated for the rest of the day. Of course, the latter fact might not have been due to the insufflation of oxygen. Not infrequently a successful experiment may bring about similar results. At any rate, both facts concern the problem of the possibility of a physiologic action of oxygen when administered by rhythmic oral insufflation, a problem which I shall not discuss here.

SUMMARY AND CONCLUSIONS

In four pathologic cases it was definitely established that the rhythmic oral insufflation of oxygen reduced or removed promptly the cyanosis, and in three of the cases the patient turned even pinkish shortly after the insufflation was begun. Without doubt these prompt effects must be ascribed in the first place directly to the action of oxygen. But it must be admitted that the rhythmic insufflation, since it is capable of assisting in the maintenance of the respiration, may be helpful in the ventilation of the lungs and thus helpful also in the removal of some of the accumulated carbon dioxid. The favorable action of the insufflated oxygen may be explained in various ways. It may simply be due to the presence of the oxygen in the blood serum in greater quantity, as a consequence of the greater oxygen tension in the alveolar air. It may be further assumed that in certain pathologic conditions the hemoglobin is not saturated with oxygen and therefore takes it up readily from the serum, and furthermore, in certain stages of the disease the oxygen thus taken up may be retained by the hemoglobin for shorter or longer periods even after the oxygen tension in the alveolar air and in the serum is again reduced. The same may perhaps be said of the other vital body cells; the nerve cells of the medulla and the cells of the circulatory neuromuscular apparatus. In the course of a disease either the cells are gradually receiving less and less oxygen, or they gradually lose the capacity for storing up oxygen, or both. There are other possibilities; but I shall not merely speculate as to which of these possible factors were the effective elements in the observations previously mentioned. But I shall point out the following facts. In one case of pneumonia the cyanosis returned immediately when the oxygen insufflation was stopped. In this case surely the vital cells had no longer any storing capacity. This patient died one hour after the insufflation was installed. In the case of another patient the insufflation had at first a marked after-effect when the insufflation was discontinued, but gradually this storing capacity disappeared and the patient was kept alive for several hours longer by continuing the insufflation without intermissions. In this patient, when the insufflation was first begun, some degree of storing capacity of the vital cells for oxygen was still present, but it was on its down-hill course, which the oxygen insufflation could neither revert nor stay. In my first patient each series of insufflations was followed by a period of freedom from cyanosis. These periods were short, but for five hours the periods did not become shorter; "the patient held his own," and he died suddenly when the period before oxygen could be again administered became too long. In this patient the down-hill course was stayed; whether it could have been reverted by further administration of properly timed insufflations of oxygen was at that time more than doubtful. But the condition of the fourth patient, who actually recovered, was, when first seen, as grave as that of the last patient. Nevertheless, the rhythmic oral insufflation of oxygen not only stayed the down-hill course, but undoubtedly assisted in reverting it to normal.

To recapitulate briefly: Four cases of pneumonia due to pneumococcus Type II were treated by oral insufflation of oxygen. In all cases the treatment began when the condition of the patients was already very grave and apparently hopeless. In all cases the cyanosis improved soon after the insufflation was started. In one case the cyanosis returned immediately after the insufflation was stopped. There was apparently no more storing capacity whatsoever for oxygen. That patient died one hour after the beginning of the treatment. In the second case there was at the beginning a definite storing capacity for oxygen which, however, gradually disappeared. The life of that patient was then kept up for several hours by continally administering the (rhythmic) insufflation of oxygen. In a third case the storing capacity was small but remained unchanged for five hours. The patient died during a prolonged period when oxygen could not be readily procured. The fourth case, which practically was as hopeless as any of the foregoing, showed a definite reversion in the direction of recovery about two hours after the treatment by means of oral insufflation of oxygen was begun.

It seems justifiable to assume that the period of definite cyanosis is preceded by a more or less long period during which the capacities for taking up oxygen, and storing it, by the vital cells, are gradually getting impaired; and it is further justifiable to assume that during early pathologic periods the insufflation of oxygen may be capable of restoring these capacities to their normal extent more frequently and efficiently than during later stages. The early insufflation might thus be the means of preventing the disease from reaching the stage of cyanosis. In other words, early administration of oral insufflation in pneumonia and similar diseases may prove to be a real therapeutic measure. In normal conditions the individual inhales air which contains about 30 per cent. oxygen above the physiologic need. This surplus presents the factor of safety for the healthy, moderately active individual. During sickness that gradually leads to respiratory insufficiency, the loss of the capacity of the vital body cells for taking up and storing oxygen, the factors of safety for this vital gas ought to be then considerably larger than in normal conditions. It is true that, experimentally, we shall be the ers. If the patient recovers under early administration of oxygen insufflation, we shall in most cases be ved of the absolute evidence that the recovery was ctually due to the treatment. But we must give the benefit of doubt to the patient.

I recommend, therefore, that in pulmonary and cardiac disease oxygen should be administered by means of the oral insufflation several times a day at an early period when there is not yet an urgent necessity details in ygen should not be considered as a terminal gratifying one. he other hand, it ovember, 1916, Dr. Cole, the director of the hospital, telephoned to our laboratory asking me to come over and administer for it. With my apparatus to a measure. On that I would again to be emphasized that oxygen should not be considered as a specific, and its use should by no means eliminate the use of other promising remedies. On the contrary, oxygen may make the body cells more amenable to the curative action of other therapeutic agents. Furthermore, the oral insufflations offer a chance to other therapeutic agents to develop their favorable action.

THE PLACE OF INFANT WELFARE IN PUBLIC HEALTH INSTRUCTION *

J. H. MASON KNOX, Jr., Ph.D., M.D.

Associate in Clinical Pediatrics, Johns Hopkins University; Physician-in-Charge, the Thomas Wilson Sanitarium; Medical Director, Babies' Milk Fund Association

BALTIMORE

Hygiene has been defined as that department of knowledge which concerns the preservation of health. It not only includes the various branches of the so-called medical sciences, but lays tribute on any knowledge or practice which may be serviceable in combating disease and in promoting health.

It is the fundamental duty of all governments to provide for the safety of their people, even at the sacrifice of individual right, liberty and property. This function is exercised under the common law as a police power, and implies the right of a government to secure for its subjects healthful living conditions. Under the government of the United States, the authority for this sanitary provision is vested in the separate states, rather than in the federal government. The latter exercises its right of control only in exceptional cases, namely, in interstate traffic, in cases of threatened general epidemics, and in maintaining advisory authority over quarantine. This federal control is exercised through the Public Health Service, a branch of the Treasury Department, while supervision over food and drugs is under the control of the Department of Agriculture; whereas the vital statistics, which form so fundamental a part of all public health work, is a division of the Bureau of the Census of the Department of Commerce.

Prior to the nineteenth century, boards of health were organized in the larger cities along the Atlantic coast, but little was done except when outbreaks of severe epidemics required that unusual steps be taken to control them. Later, local boards of health were formed in other inland communities; but the first state board of health was organized in Massachusetts, in 1869. Since then, in practically all the states, some duly authorized body has had charge of matters pertaining to public health. In many states there are laboratories where various examinations are made for physicians practicing in the state. In the laboratories of other states valuable research work is being carried on.

The functions of the state boards of health have been developed in a haphazard rather than an orderly fashion. Each state has gone its own way, often regardless of the experience of other states and countries, and much time, money and labor have been wasted because of lack of cooperation. This is in no small measure due to the domination of politics and to the fact that there exists in the United States a serious lack of trained and experienced hygienists.

To supply this need for competent workers in public health, a number of medical schools are offering more or less extensive courses in preventive medicine, and there are a few thoroughly equipped institutes of hygiene.

In connection with ten medical schools, at present, graduate courses in public health have been established. Seven of these schools give the degree of Doctor of Public Health, three after a two years' course, and four after a one year course. The degree of Certified Sanitarian is given by one university, after a one year course, to graduates of arts and sciences. The degree of Master of Public Health is conferred by two medical schools, and the degree of Master of Arts of Public Health, or Master of Science of Public Health, is given by three other universities, and the degree of Graduate of Public Health by one.

The subjects considered in one of the more complete courses in public health include preventive medicine and sanitary science, consisting of epidemiology and tropical medicine; personal hygiene, having to do with choice of foods, ventilation, exercise, sleep, etc.; industrial hygiene; public health administration; sanitary biology and chemistry; communicable diseases; sanitary engineering; demography; eugenics; infant mortality; school hygiene, and tuberculosis and venereal prophylaxis.

Even such a cursory summary of information to be obtained at a well established school of hygiene must convince physicians and intelligent laymen of the value to the future well-being of the country of the propagation of such knowledge; and all physicians will admit that but a small proportion of this knowledge, in its relation to public health, is given in the ordinary medical school curriculum. In other words, it has become evident that preventive medicine is a distinct, specialized science, offering unusual opportunities of service to those well equipped students who care to pursue it.

---

* Read before the Section on Preventive Medicine and Public Health at the [illegible] Annual Session of the American Medical Association,

When we consider that there are constantly about 3,000,000 people sick in the United States, involving an annual financial loss of more than $500,000,000, and that a considerable proportion of this illness is preventable, it is readily understood that preventive medicine offers a field almost unique in its service to humanity.

It is the purpose of this paper to present briefly the importance of infant welfare work in any properly considered and thorough instruction in public hygiene.

Several general facts in reference to infant mortality would seem, of necessity, to place infant welfare work, that is, all efforts to reduce infant illness and death, in the van of any movement having to do with public health. These facts are briefly as follows:

Eighteen per cent. of the total mortality of all ages occurs under 1 year. Infant mortality can be reduced by known methods, from one death within the year, to every five babies born (which is the rate in many portions of the country), to one death in every twenty babies born, which is the rate under satisfactory hygienic conditions, and which means the saving each year in the whole country of approximately 200,000 lives, a larger number than would be saved by the complete eradication of tuberculosis. If the capitalized value to the state of an infant life is, as has been claimed, $5,000, the loss of wealth represented by this human wastage can be roughly estimated. It is to be emphasized, too, that babies who come healthily through their first year look forward to a much longer life expectancy than do the cured patients from any illness.

As has been well said by Dr. Woodward of Washington:

> The day has gone by when the public health officer can look on the abating of nuisances and the control of preventable diseases as the chief part of his duty. Infant mortality presents as great a problem for the health officer as does smallpox, scarlet fever, infantile paralysis, school hygiene or anything else.

In presenting the subject of infant welfare to students of hygiene, three distinct lines of approach should be followed. In the first place, infant welfare must be studied in relation to other branches of hygiene, of which it is an integral part. Therefore, much that should be taught in the general curriculum of such a school requires no duplication in presenting the subject of infant welfare, except that the relation of the latter to the subject considered must be emphasized. For it is true that nothing is done in the community to improve health conditions in general which does not help the baby. Thus, for example, vital statistics, particularly birth registration, form the foundation of any intelligent infant welfare work. These subjects would, of course, be presented in relation to other matters of public health. The same can be said of general sanitation, housing, water supply, milk supply, and of industrial occupations and venereal disease in their relation to the health of the infant. Secondly, measures already in operation should be thoroughly studied and compared, and those best suited to any given community should be determined. For example, in some cities distribution of modified milk, or the encouraging of day nurseries, or the licensing of midwives, may be distinctly advantageous, whereas in other cities they might be harmful. Thirdly, not only should we "prove all things and hold fast to that which is good," but an institute of hygiene offers incomparable opportunities for ascertaining new facts which should lead directly to the saving of infant life.

In suggesting a brief outline for the study of infant welfare, I avail myself, among other sources, of the *Transactions* of the Association for the Study and Prevention of Infant Mortality, and of many valuable suggestions of Miss Knipp, its executive secretary.

It would seem that infant welfare falls naturally into two main divisions, one of which has to do with having better babies born. It presents as an ideal that every conception should result in a healthy baby. This leads at once to a discussion of the science of genetics and eugenics. Here one must tread cautiously, as there is much in theory which cannot be put advantageously into practice. It would seem, however, that the reasons for the prevention of the marriages of the notoriously unfit, and of the segregation or the unsexing of such persons, should be presented from the standpoint of the baby's welfare. Again, the effect of acute and chronic alcoholism, or of the abuse of other habit-forming drugs, in one or both parents, on the well-being of the child should be discussed from a thoroughly scientific point of view. The whole question of syphilis should be studied with special reference to stillbirths, premature births, and lowered infant vitality. The effect of tuberculosis in parents on the vigor of the offspring must be presented; likewise the effect of factory work, or hard manual occupation, on the part of the pregnant woman.

Then, in connection with the obstetric department, steps should be taken to bring about more skilful, aseptic obstetric practice. The question of training or abolishing midwives in this country, the early registering of expectant women at the obstetric clinics, thorough prenatal care, adequate obstetric service in rural districts, the establishment of obstetric substations under the control of health departments: these and similar subjects having to do with getting babies well born are parts of infant welfare.

A second division of the subject would consist of a study of the causes of illness and death during the first year. These divide themselves into several important groups, which should be discussed separately:

1. *Congenital Debility, Prematurity, etc.*—It has been long known that a third of the deaths in the first year occur in the first month, many of them in the first week of life. The reasons for this are not thoroughly clear, but the data should be collected and carefully analyzed.

2. *Digestive Diseases.*—It is in this group that nearly all the progress made in recent years, in reducing infant mortality, has taken place. The various plans carried out in this country and abroad which have resulted in the reduction of disease and death from digestive disturbances should be presented from a historical point of view, and those means which are most efficient and best applicable to our own conditions should be pointed out.

3. *Diseases of the Respiratory Tract.*—This group of ailments presents now a danger to the infant practically equal with the diseases of the intestinal tract; but little light has been thrown on the subject, and much of our knowledge of the spread of pulmonary infections has not been made use of in pediatrics.

4. *Acute Infections.*—Fortunately, the baby leads a partially isolated life. It is peculiarly susceptible, however, to infections, and should be protected from them. When infectious diseases are controlled among

schoolchildren, through proper sanitation and health administration, the infant will be the gainer.

Other conditions, resulting in the destruction of infant life, including deformities or defects in development, are little understood, but are almost negligible compared to the loss of life from the conditions already referred to.

Another group of babies among which there is a high mortality, and which require unprejudiced, tactful treatment, are the babies at present reared in institutions, many of whom are of illegitimate birth. The reception of these children by institutions began in the seventeenth century, under the advice of St. Vincent de Paul. This practice has tended to increase both illegitimacy and infant mortality. No better illustration could be given of the fatal partnership of good intentions and wrong methods, and it is on questions such as this that the impartial balanced judgment of an institution devoted to scientific hygiene can be of incalculable value. It is important to show to future health officers that immorality is checked, the mother's self-respect restored, and many sturdy infant lives saved, by keeping mother and baby together during the early critical months, and in helping her to secure remunerative occupation amid sympathetic surroundings. We need unprejudiced investigation of the mental capacity of many of these unmarried mothers. We need, too, a light on the notoriously large mortality in institutions, and directions as to the best methods of reducing it, or of substituting foster homes for children bereft of parents.

A large number of other topics must be considered in any complete outline of courses on infant welfare. Some of them are:

1. Study of the milk supply of a community in relation to infant welfare. This could be carried out in connection with other courses in sanitary milk production.

2. Maternal nursing, in its relation to infant mortality, particularly in the homes of the indigent.

3. Housing conditions, which are of fundamental importance in the well-being of the infant. In this connection it should be stated that in any institution situated in a southern city special emphasis must be laid on the health conditions among the negro population. In view of the fact that the negro presents more than double the white death rate and morbidity rate, especially for infectious and venereal diseases, this race constitutes a problem of its own in which infant welfare plays a vital part. The negro needs more sympathetic and kindly, but firm, treatment, and less exploitation. Their low living conditions in many parts of the South, the prevalence of infectious disease and puerperal fever among them, and the kind of food they give their children leaves everything to be desired; and yet there are 10,000,000 of them among us, thus constituting more than 10 per cent. of our total population. It is estimated that about half a million of this number are constantly ill, thus entailing a loss of millions of dollars in the communities in which they live.

Another subject in which the infant is gravely concerned is the wage of its parents. Insufficient income and the resultant low standard of living are always associated with high infant death rate. This has been shown by a number of recent investigations, notably in Johnstown, Pa., where the infant mortality in families earning less tha $10 a week was more than 200 per thousand, while, hen the income was more than $25 per week, the infant mortality rate was about 80 per thousand. These and similar facts demand careful attention, not only in an institution of hygiene, but also on the part of sociologists. Can they be met by the gradual raising of the standard of our wage earners, by a system of health insurance, or will the working men in America, as in other countries, eventually limit the size of their families? Low wages for the men of the family make it necessary, of course, for the women of the family to work to avoid starvation. This results in absence of the mothers from home and in the neglect of the children. It is interesting to recall that in Lowell, during a strike, when the mothers could not work, infant mortality was reduced; and that during the siege of Paris, when the general mortality was doubled, the infant death rate was halved.

5. This leads to a consideration of what is perhaps the most important element in the welfare of babies, namely, intelligent care on the part of their mothers. No outline of courses having to do with infant welfare would be worth while that did not stress as perhaps its pivotal point the importance of the education of the present and future mothers of the country in those matters pertaining to the feeding and care of their children. If this instruction can be given in all our schools, and the social conditions can be adjusted so that wages compatible with decent living are possible for all families that are willing to work, much of the infant mortality problem would be solved. This education of girls in infant welfare has been carried on, in some form or other, in various parts of the country, for a number of years, in private and public schools, and in so-called continuation schools, and in "little mothers' health leagues."

It is the duty of an institution devoted to hygiene to study the character of this instruction and the results obtained when these girls have homes of their own, and to determine what forms of instruction may be best adapted to particular communities.

The child of run-about age, between the infant and the school boy or girl, also needs special study. He suffers often from neglect, from improper food and clothing, and from the lack of fresh air. Many serious conditions start before school age begins.

The infant mortality movement, as it is generally understood, began in France in 1892 with the "consultations des nourissons" of Budin. From this time on, in an incredibly short period, infant welfare work of various kinds has spread over nearly the whole civilized world. Milk stations have been organized in many large cities, hundreds of nurses and physicians are devoting their time to this form of philanthropy, and divisions of child hygiene have been organized in the departments of health in New York, Philadelphia, Boston and other cities.

The care of the expectant mother is now conceded to be essential for thoroughgoing infant welfare work.

The National Association for the Study and Prevention of Infant Mortality was organized in New Haven, Conn., in 1909, and since then its office has exerted a guiding influence in this whole movement. The *Transactions* of the society reflect the progress that has been made. In 1912 a federal Children's Bureau was established, in which infant welfare work was made a feature. This bureau has made a number of exceedingly valuable investigations on the infant mortality rate under various urban and rural conditions. Divisions of child hygiene have been created in several state departments of health, including New York, New Jersey, Kansas and Ohio.

It should be the purpose of an institute of hygiene to acquaint the students taking infant welfare courses with the history of the movement and with the methods that have been used in other countries and in our own to conserve infant life. New Zealand, with its infant mortality rate of less than 5 per cent., deserves special consideration.

Finally, in many cities, in cooperation with existing agencies, such as the infant welfare associations, the health departments, and the obstetric and pediatric departments of medical schools, it is possible for students of hygiene to obtain a large experience in practical infant welfare work on the field; to see for themselves the many examples of the deleterious influence on the baby of poverty, bad housing conditions, improper food, and ignorance on the part of parents, and to note also the dire results of long institutional life on young infants. These students will thus have abundant opportunity to form their own conclusions as to the efficiency of the various agencies in meeting and correcting circumstances so inimical to infant health.

If the subject of infant welfare work can be presented in some such fashion where instruction in hygiene is thoroughly given, no interested student could receive his degree and take up his public health work in any community without knowing something of the value of infant life and something also of the measures best adapted to promote it.

At this time of stress and danger, when the youth of the land are about to offer themselves for the service of their country in battle and many of them may be called on for that last measure of devotion, it is especially timely that all efforts tending to improve the health of the people should be fostered, and particularly is it vital that the infant population, on whom in due time the future of our nation must depend, be carefully enumerated and conserved.

ABSTRACT OF DISCUSSION

Dr. William H. Welch, Baltimore: The most promising line of attack on the prevailing death rate is to control the diseases of childhood. We can accomplish more there, make more impression, and it makes a stronger appeal than anything else, I think, on the community at large.

As regards the relation of school hygiene and public health to this work, that, again, seems to me so apparent that it requires no particular emphasis. As to the details of that I am hardly prepared to speak. It is obvious such an institution must be in close connection with the pediatric clinic during the organization of the service of the schools or hospitals, which have been such a tremendous accession for our municipal and state departments of health, especially in the work that the Public Health Service has done in that connection, and with all the official and voluntary organizations, of which we have so many. Those who are studying in this field should have every opportunity. Perhaps I should like to emphasize as much as anything, although it is only one of the many functions of school hygiene, the importance of increasing our knowledge on the subject. While it is true that we do not apply, or begin to apply, all that we know, nevertheless the whole field is full of still open and unsolved problems; and nothing is more certain than that failure revolves around this, when we attack the problem of controlling a given disease without spreading active knowledge as to the mode of origin and the spread of the disease.

I should like to know a little more of why it is that there is such a tremendous difference between the so-called individualized care of the infant at home, boarding out, and in institutions; and I expect that field can be narrowed a great deal more than it has been.

Dr. Henry Dwight Chapin, New York: There was one question raised by Dr. Welch as to the cause of the difference of the mortality in boarded out babies and in institution babies. There are several causes that favor the high mortality of institutions for the baby; and here is the proper point at which this question must be attacked, and successfully attacked; the very high mortality in infants can be checked right there. First is the lack of a sufficient number of attendants. Babies are brought into the world singly, and not in droves; and they are not intended to be cared for in great masses. And the second reason is, they do not get enough fresh air. They lack a sufficient supply of fresh air that very few institutions can give them. Third, they lack a mother; and if they cannot get their own mother, they ought to have somebody else's mother. The subject of boarding out has not been sufficiently studied, nor sufficiently systematized. If the same work, the same attention to detail, the same study were given to putting these little babies into homes as is given to institutions, we would cut the mortality in half at once. They must be boarded out in units, under the constant supervision of a physician and nurse who are familiar with this class of cases and competent to deal with it. The Speedwell Society has successfully operated along these lines for the past fifteen years.

Dr. Rowland G. Freeman, New York: I do not want to discuss the excellent paper of Dr. Knox so much as I want to say a word for institutions. All the evidence that we are getting now from people studying these infant problems is in favor of the boarding out of children. I myself feel that an institution is the best place for a child, if it is a good institution. We have our old institutions that had 100 per cent. mortality; we have, more recently, institutions with 20 to 30 per cent. mortality; and we have other institutions where we keep the children out of doors, where we have plenty of nurses, and where children do better than they do in their homes; and I am in the habit, with difficult cases, of sending them to a hospital where they can have good, fresh air, proper food, and good nursing, and they do much better than they do in the homes. The institution has to exist as a clearing-house for babies. It is all well enough to board them out; and I believe that is the best solution for the large proportion of the babies coming to our institutions; but you must have the institutions to receive them and board them out; and you have to have the institutions to take care of them when sick. One reason why large institutions are rated as having such a large mortality is because all of their hundreds of boarding-out children when they get sick come back to the institution and the institution, not the boarding-out home, where they become sick, is credited with their deaths.

Dr. A. F. Hess, New York: I should like to say a word, also, in favor of the institution. I do not believe, with Dr. Chapin, that there is anything inherently good or inherently bad in institutions or in the boarding-out system. They can be well managed, or they can be poorly managed. Now as regards the boarding-out system, there are no statistics which show that it can be better managed than an institution. I have seen mothers who take care of babies, mothers who are licensed by the department of health, whom you would not think of entrusting with the care of babies. It is true that the department of health is now doing much better in this respect. I understand that there are now some 500 who are entirely trustworthy, but we must remember that we need 5,000 such mothers, as there are 5,000 babies to be boarded out. I believe that mothering is a very bad thing for a baby; mothering often leads to tuberculosis. I find at the Preventorium that a great number of the infants have developed tuberculosis from contact with the mother who had an open tuberculosis. Furthermore, it is not infrequent for babies to develop colds, pneumonia and die owing to the fact that the mother has had a cold. I have therefore come to believe that a baby is much better off if left alone and not mothered too much. We should not be too radical or destructive. There may be good boarding-out systems and be good institutions; let us make use of the good and abolish the poor ones.

Dr. J. H. Mason Knox, Jr., Baltimore: The institutional care of young babies is a question of the character both of the institution and of the foster home. In institutions as constructed years ago and which have an inadequate number of poorly trained attendants, the infant mortality is frightfully high; much higher than in even indifferent foster homes.

The term "mothering" has been objected to on the ground that it may imply too much fondling. We might perhaps better substitute the phrase, "individualizing care." I agree with Dr. Hess that too much unintelligent mothering is a great disadvantage; but I believe that the baby, absolutely dependent, as it is, on others, does best when it has individualizing care; this cannot be obtained unless there is one caretaker for every three or four children. When this is furnished so that the babies' wants are promptly supplied, and there is abundant air space and quiet, it really does not make much difference whether the baby is in an institution or in a foster home.

SIMPLIFIED TECHNIC IN LAMINECTOMY*

WITH DESCRIPTION OF COMBINED LAMINECTOMY AND SPINE FIXATION BY BONE TRANSPLANT

F. J. GAENSLEN, M.D.
MILWAUKEE, WIS.

The operation of laminectomy has become so well standardized that one feels a certain hesitancy in presenting modifications. However, the technic that I have employed during the past few years has been found rather simpler than that of methods previously described, so that a description of it appears warranted.

Briefly, the essential point lies in the fact that instead of stripping the soft parts and the periosteum from the posterior vertebral spines on either side and then cutting off the spines at their bases, the spines are split longitudinally into right and left halves, just as in the Albee operation for insertion of a bone transplant in Pott's disease. However, instead of deflecting the halves on one side only, as in the Albee technic, the split halves are deflected on both sides. It is then a very simple matter to separate the periosteum with attached soft parts from the laminae as far laterally as the articular processes. The posterior spines should be split well down to their bases. There is then left only a small remnant of the process to be cut away with bone cutting forceps. The cutting away of the laminae can be accomplished by any one of the numerous methods advised.

Details of Technic.—The first steps are like those in the Albee spine fixation. A curved incision is made slightly to one side of the row of posterior spinous processes through the skin and subcutaneous tissue. The flap is rapidly reflected, exposing the deep fascia on either side of the middle line. With a stout knife, a straight incision is made down the middle line, splitting the supraspinous ligament and incising or at least marking the tips of the spinous processes themselves. A tenotomy knife is now used to dip down between the individual spinous processes, dividing the interspinous ligaments. With a very thin chisel the spines are now split through the line indicated, care being taken to keep as close to the middle line as possible. On reaching the base of the spinous processes, the chisel is driven slightly to one side, and the corresponding halves are broken and deflected to that side. With a gauze sponge over a periosteal elevator, the periosteum is now stripped from the corresponding laminae to the articular processes. This is easily and quickly accomplished without injury or fraying of the periosteum with the clean start obtained, as just indicated. It is the ease and rapidity with which this can be done, and the relatively slight hemorrhage encountered as compared with other methods, which particularly recommends this procedure. With a few strokes of the chisel the opposite standing halves of the posterior spines are now broken off close to their bases, and deflected to the side, the periosteum being stripped back as on the opposite side. The next step consists in biting off with suitable forceps the remaining portion of the bases of the spinous processes and cutting through the laminae by any one of a number of suitable methods. The Hudson drill and a number of rongeur forceps of suitable size and shape will answer the purpose very well. After removal of the laminae, the spinal contents are dealt with as circumstances demand.

The closure of the wound is in no way complicated by the method of approach outlined. In fact, the clean cut wound edges showing the split halves of the spinous processes and the split supraspinous and interspinous ligaments offer good opportunity for accurate approximation. When the split spines are not too thick a stout, full-curved cutting needle can be passed directly through the corresponding halves, holding them in firm apposition. This is not necessary, however, as they will be held sufficiently firm by sutures taken through the periosteum or the dense ligamentous tissue above and below. A few intermediate sutures serve to unite the interspinous ligaments. The preservation of the spinous processes, so far as they have been split, though by no means an essential to firm union, may be regarded as a distinct advantage in securing greater firmness and accuracy in closure.

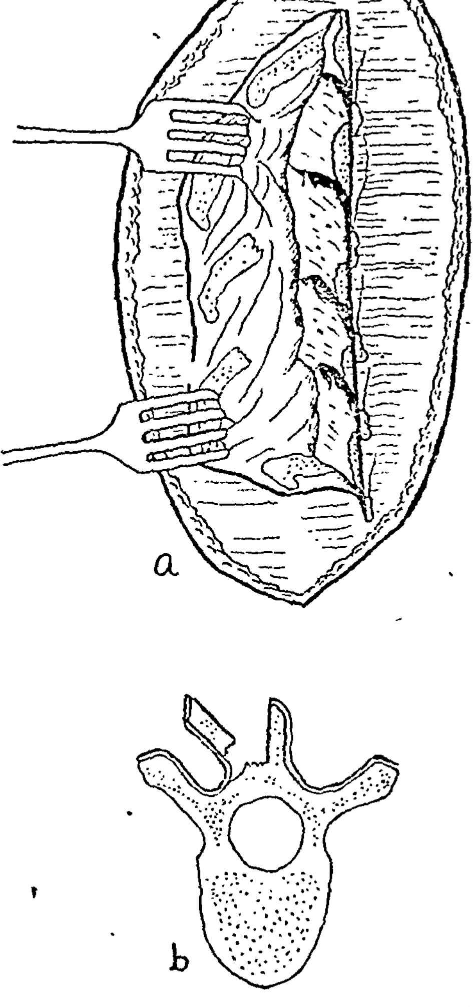


Fig. 1.—Posterior spinous processes (*a*) split in the middle; the left halves are deflected with the periosteum, leaving the denuded laminae on that side exposed; the right halves remain standing; *b*, cross section, showing splitting of posterior spinous process and denudation of lamina on left.

In one instance, when a laminectomy was done for fracture of the fifth cervical vertebra, death occurred some six weeks after operation from ascending kidney infection and trophic ulcers. The laminectomy wound had healed perfectly and the split halves of the spinous processes were firmly adherent to one another, though with a little force they could be separated with a snap, showing that bony union was well under way.

---

* Read before the Section on Orthopedic Surgery at the Sixty-Eighth Annual Session of the American Medical Association, New York, June, 1917.

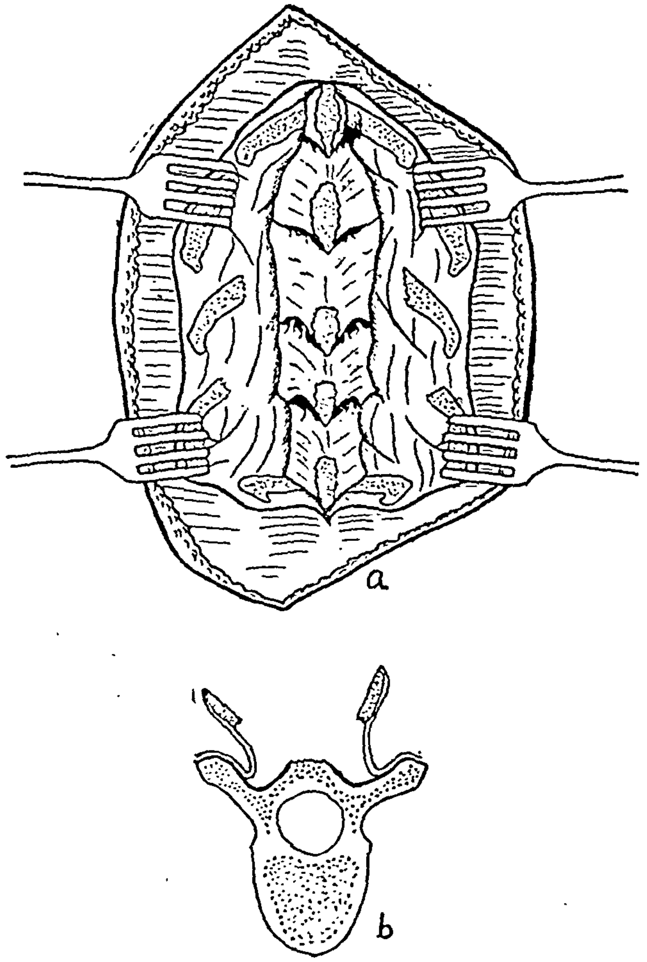

Fig. 2.—Broken spinous processes (*a*) deflected on both sides, exposing denuded laminae on both right and left; *b*, cross section.

The advantages of the method of approach, outlined above, are: (1) rapidily; (2) diminished trauma; (3) diminished hemorrhage, and (4) more accurate and firmer closure, by virtue of the union of the bony components.

In certain instances, after laminectomy for urgent cord pressure symptoms, it may be desirable to fix the spine by means of a tibial transplant immediately after decompression of the cord. After the usual operation practiced heretofore, in which the spinous processes are sacrificed, a bridging over of the laminectomized area by means of a tibial graft would be a hazardous proceeding, the graft receiving bony contact only above and below the laminectomized region. This hazard would naturally increase with the length of the laminectomized area. It may be regarded as a universally accepted fact that a bone graft has far better chances of becoming firmly united if it is in contact with numerous healthy bone surfaces. The method of approach, indicated above, by preserving the spinous processes and therefore retaining the usual number of bony contact points, paves the way for a successful combination of laminectomy and spine fixation by means of the bone graft. This plan was carried out in two cases, in both of which a diagnosis of vertebral tuberculosis had been made with urgent cord symptoms. After decompression of the cord, by laminectomy, performed according to the plan just outlined, several healthy spines above and below were split after the usual manner. The left halves were deflected while the right halves remained standing. A graft of sufficient length was then cut and put in place, bridging over the laminectomized area and finding anchorage above and below on the standing halves.

In both instances, primary union was obtained. In the first case, one with a middorsal lesion, the spine is held perfectly rigid, the graft fulfilling its mechanical function perfectly. In the second, a case of cervical Pott's disease with urgent symptoms, death occurred about four weeks after operation from an ascending urinary infection.

To be sure, indications calling for the employment of this combination of procedures will be encountered only rarely. Traction and recumbency in the hands of most orthopedic surgeons will prove adequate in the vast majority of cases, but in certain cases of Pott's disease, possibly also in some cases of fracture of the spine, a combination of the two will be found desirable. The experience in the cases just reported would indicate also that the method is feasible.

141 Wisconsin Street.

ABSTRACT OF DISCUSSION

Dr. Edwin W. Ryerson, Chicago: My experience with this operation is confined to one case, which I had recently, for fracture-dislocation of the spine. The procedure of Dr. Gaenslen was not exactly followed, in that I used a motor saw to split the spinous process, thereby causing less traumatism than when the chisel and mallet are used. The operation was nearly bloodless, much less hemorrhage being encountered than when the spinous processes are exposed and cut away by the rongeur. This procedure is the more valuable, as it gives an opportunity to put in a bone splint in cases of pressure on the spine caused by tuberculosis. These cases do not often require laminectomy; but when they do, one would hesitate to do a simple decompressive laminectomy, if there were no possibility of fixing the spine afterwards; but with one of the tibial splints, we may properly hesitate less to do it than in the past.

OPERATIVE TREATMENT OF TUBERCULOSIS OF THE KNEE JOINT IN ADULTS*

ROBERT B. OSGOOD, M.D.
AND
EDWARD C. BULL, M.D.
BOSTON

Tuberculosis of the knee joint in adults differs in two important points from the same disease in children.

1. In children we have centers of growth in direct anatomic relation to the joint. Disturbance of these centers by the disease or by operative interference may seriously affect the ultimate length of the limb. This condition requires consideration and treatment.

2. In children there seems to be a more marked resistance to the disease than in adults, and cures with only slight disturbances of function often occur when persistent and continuous local fixation is combined with general treatment by heliotherapy and an antituberculous regimen.

In adults, the disease when once established, in our experience, may be said never to recover fully without operative interference of some form.

We realize that this is a sweeping and dogmatic statement, but we have yet to see a tuberculous disease of the knee joint in which the diagnosis has been conclusively established by means of tuberculin tests showing general and local knee joint reaction, by means of examination of tissue removed for purposes of microscopic study, or by means of positive guinea-pig inoculation of fluid removed by aspiration, gain a lasting recovery without operative interference.

DIAGNOSIS

We do not believe that the diagnosis of tuberculosis of the knee joint in adults can with certainty be made in the early stages of the disease from clinical examination alone. Several other monarticular affections may well be mistaken for it; a gonorrheal infection of subacute character; a syphilitic infection; a villous arthritis; a simple chronic synovitis of unknown origin, or a chronic traumatic arthritis.

We shall not attempt to indicate the important points in the differential diagnosis, but rather to emphasize the fact that in our opinion it cannot at times be made without the help of the laboratory tests enumerated in the foregoing. It is fair to say that any rather subacute affection of the knee joint, in which the subjective symptoms are often intermittent and which objectively is characterized by a persistent but variable change in the external contour of the joint and an atrophy of varying degree of calf and thigh, should be considered to represent tuberculosis of the knee joint unless there exists proof to the contrary.

We have become convinced that tuberculosis of the knee joint in adults is at times primary in the synovia. Our belief is based on the failure to find evidence of bone involvement by careful Roentgen-ray examination, by macroscopic examination at operation, by subsequent recovery as the result of arthrotomy and the injection of 4 per cent. iodoform and olive oil emulsion, and on the positive evidence of tuberculosis of the synovia by microscopic examination and the positive inoculation tests of guinea-pigs with the removed tissue or joint fluid.

TESTS

We have found the von Pirquet test to be of only negative help in excluding tuberculosis.

If the patient has no elevation of temperature and is placed on a two-hour chart, and if he reacts to a subcutaneous injection of Koch's old tuberculin by a slight or marked febrile rise and an increase in the local joint symptoms, as indicated by greater sensitiveness, added heat, or both, we believe an almost positive diagnosis of tuberculosis of the knee joint may be made. It is the practice of the clinic with which we are associated to begin with an injection of 0.1 mg. If no reaction occurs in two days, an injection of 1 mg. is given. If still no reaction, two days later an injection of 3 mg. is given, and if there remains no reaction to this and to a last injection of 5 mg., we consider the test to be negative.

We have no statistics as to the percentage of cases later proved positively to be tuberculosis in which this test fails to give any local or general reaction. We know that we sometimes fail to obtain it, but our impression is that the percentage of failures is very small.

ROENTGENOGRAPHIC EXAMINATION

The diagnosis by roentgenogram is often confirmatory, but opinion should in few cases be made conclusively from this evidence when considered alone. Tuberculosis is a destructive process, and when the bone is affected, loss of substance will often be shown; but when the disease is creeping in beneath the articular cartilage, it may not be evident in the roentgenogram. There is occasional lime salt deposit beneath the periosteum. Typically there is a hazy appearance of the articular surfaces.

The Wassermann reaction and the gonococcus complement fixation reaction are done as a routine in this clinic.

OPERATION

It is our belief that an operation should be contemplated as soon as the diagnosis has been made. It is often wise to defer the operation in a case in which there has been no fixation and in which the knee is in a more or less acute and irritable state. Such a patient should be put at once at complete rest and freedom from weight-bearing for perhaps a month, and when the acuteness of the disease has subsided, the appropriate operative procedure may be more safely executed, with less postoperative reaction.

Only two types of operation have for many years been considered in the clinic: the one conservative of function and representing little or no shock, attempting to cure the disease by keeping synovial surfaces apart and bathing them in an antiseptic oil; the other destructive of function, a major operation, attempting to cure the disease by destroying the joint and eliminating the synovial membrane and the red bone marrow.

When we believe that the tuberculous disease exists only in the synovia, we have been advising our adult patients to submit to an exploratory arthrotomy through a 3 inch lateral incision, and if no bony disease can be found at operation and the macroscopic findings are consistent with tuberculosis, we have been injecting a bland olive oil containing 4 per cent. of iodoform after the method of Brackett.[1] A considerable number of these patients (eight out of thirty) with tuberculosis of the knee have apparently been cured in his hands and able to regain function. For the technic of the operation, the reader is referred to Brackett's carefully written and excellently illustrated paper. Suffice it to say that from 1 to 5 ounces of the 4 per cent. iodoform oil are injected after the joint has been opened, the fluid evacuated, and the adhesions and pannus, if it exists, carefully separated. The deeper layers of the capsule and the synovia are closed by a continuous stitch from each end, a small opening being left in the middle for the nozzle of the glass syringe. A special double loop lock stitch is inserted and pulled tight about the nozzle, and the oil injected with considerable tension and the lock loop pulled home. Oil has been recovered from the joint eight weeks after the operation in an apparently unchanged condition.

TABLE 1.—CASES OF BONE AND JOINT TUBERCULOSIS TREATED FROM THE OUTPATIENT DEPARTMENT OF THE MASSACHUSETTS GENERAL HOSPITAL FOR TEN YEARS UP TO 1917

	No.
Total cases treated in outpatient department	239,867
Total cases treated in orthopedic department	20,079
Cases of bone and joint tuberculosis	1,336
Cases of tuberculosis of knee treated in outpatient department	206
Cases of tuberculosis of knee treated in orthopedic department	181

For the detailed after-treatment, the reader is again referred to Brackett's article. Complete fixation is never employed, though the patient bears weight in a split cast only after several months. The cast is removed every day for gentle passive movements. Sometimes two, and in a few cases three, injections are given if we can obtain no evidence of the involvement of the bone and the evidence of active synovial disease still exists.

If the evidence presented shows that disease of the bone exists, we have come to believe that excision is the procedure to be unqualifiedly advised. As we have said previously, if the disease is acute there should be an initial period of complete rest and fixation, but we have never seen permanently satisfactory function restored in a knee joint in which tuberculous disease has involved the bone. The disease often becomes quiescent under complete fixation, but subjected to use without protection, these apparently healed joints light up, and the disease advances, though the history may extend over a period of years.

We do not maintain that there never has existed a permanent cure of tuberculosis of the knee joint which has involved the bone, without an excision or an erasion or some procedure which obliterates the joint, but we do say that we have never seen one, and until we do we shall continue to advise for these cases excision as the method of choice.

Technic.—In discussing the technic of the operation for excision of the knee we shall describe that which after a period of years has seemed to us the more useful. The most careful two day or three day preparation of the skin is given. A tourniquet or an Esmarch is applied.

Incision.—A wide U-shaped incision is plotted by making three or four small skin scratches which will run at right angles to the U-shaped skin incision. Through these the main incision is made, and by matching the skin scratches, eventual nice apposition of the skin is made easy. The incision is carried down to the bone, from condyle to condyle, through the patellar tendon. The patella and flap are pulled upward, the crucial ligaments cut as the knee is flexed, and the whole joint cavity exposed. A quick, moderately complete dissection of the tuberculous tissue is carried out, and the patella, if badly diseased, is removed. If only its cartilage is affected, the articular surface is removed with a saw, and it is used later as a bone graft.

The really important judgment of the operation must be exercised in determining the amount of bone to be removed and the plane of the cuts. If paper patterns of the bones as shown in the lateral roentgenograms are cut before the operation and the amount of flexion to be desired because of the social conditions of the individual patient be determined, these patterns can be made to indicate in a fairly accurate way the planes of the saw cuts.

The determination of how much permanent flexion it is advisable to obtain for the patient is an important question. It is more than is generally thought to be wise. Brackett especially has called attention to the usefulness of even 45 degrees of permanent flexion in a man with a largely sedentary occupation. With a high sole and heel, walking is not as awkward as would be expected, and is more than offset by ease in sitting.

Our opinion is that in a man or woman with a sedentary occupation, from 35 to 40 degrees of flexion is the position of choice. If the work is to be chiefly ambulatory, from 15 to 20 degrees seems to offer the best functional position.

The bone is removed best with a miter saw, and after the slices have been taken from both femur and tibia, and perfect apposition in the desired position has been obtained, the posterior disease is removed down to the capsule.

We have become convinced that some method of internal fixation of the bone ends is greatly to be desired. Union is certainly quicker, postoperative pain is less, and early union favors early cure. Reference is here made to a study of the end-results of excision of the knee made by one of us.[2]

The method of internal fixation by means of bone plates and screws or by the Goddu aluminum wire clamp is satisfactory in many cases. The fact that in a considerable number of cases these plates or clamps had to be subsequently removed did not seem to delay speedy and satisfactory cure of the disease or early firm union. Two flat vanadium or plain steel plates have been most commonly used, placed laterally on the inner and outer sides. These plates may be quite accurately shaped before operation by cutting out a paper pattern of the anteroposterior roentgenogram, performing a paper excision, and fitting the plates to the lateral outlines. There are many cases, however, in which the atrophy of the bones is so considerable that even coarse-threaded wood screws get no grip and the plates offer little if any fixation. In such cases and in certain others (in order to try the method) we have been employing a suture of kangaroo

TABLE 2.—CASES OF BONE AND JOINT TUBERCULOSIS TREATED IN THE MASSACHUSETTS GENERAL HOSPITAL IN THE THREE YEARS PRECEDING 1917

[2] Osgood, R. B.: Boston Med. and Surg. Jour., July 24, 1913, p. 123.

tendon, which we believe to be useful. It may be called a "bundle knot tie," and is made with double kangaroo tendon for double strength, less likelihood of cutting, and greater length of tie. With a hand drill, in the end of which is a large eye, while the knee is flexed, a hole is bored straight through the femur from front to back, about 1.5 cm. above the cut surface. It may be necessary with a periosteum elevator to free the posterior capsule upward on the femur and downward on the tibia. With the knee flexed there is no danger of wounding the vessels if the drilling is carefully done. Through the eye of the projecting drill the two ends of a stout kangaroo tendon suture are threaded and pulled back. A second suture is now looped to the first and its two ends pulled through a symmetrical drill hole in the tibia. Next, a hole is drilled through the femur from side to side about 2 cm. above its cut surface, and a double kangaroo suture drawn through. Its looped end is looped to a fourth suture, which in turn is drawn through a corresponding hole in the upper end of the tibia. When the knee is extended and the apposition is accurate, the knots are tied tight and give a surprising amount of fixation. If only the joint surface of the patella has been removed, a bare bone bed is prepared for it and the sutures tied through and over it.

TABLE 3.—END-RESULTS IN SIXTY-NINE CASES OF TUBERCULOSIS OF THE KNEE IN ADULTS TREATED BY OIL ARTHROTOMY AND EXCISION; OPERATIONS DONE ON THE ORTHOPEDIC SERVICE OF THE MASSACHUSETTS GENERAL HOSPITAL, 1907-1917

	No.
Cases of oil arthrotomy	17
Cases of excision of the knee	52
Oil arthrotomy results:	
(a) Apparent cures	4
(b) Improved patients	4
(c) Patients not improved (1 died)	6
(d) Patients lost sight of	3
Means of internal fixation in excisions:	
(a) No internal fixation	1
(b) Bone plates, wire clamps or nails	30
(c) Kangaroo tendon	21
Secondary operations required:	
(a) Oil arthrotomy	4
(b) Excision	4
(c) Reexcision	4
(d) Amputation	7
(e) Removal of plates, wire clamps or nails	14
Number of excision cases with firm union	38
(a) In one month or less:	
Bone plates, etc.	6
Kangaroo tendon	0
(b) In one to two months:	
Bone plates, etc.	4
Kangaroo tendon	2
(c) Three months or more:

Kangaroo tendon	9
	Months
Average time required for bony union in last 24 cases	9.2
(a) In cases with bone plates, nails, etc.	9.5
(b) In cases with kangaroo tendon	8.25
No record of eventual union (including amputations):	
	No.
(a) Bone plates, nails, etc.	4
(b) Kangaroo tendon	10
Mortality	1
	14
Failure to avert disease:	
(a) Oil arthrotomy (1 patient died)	6
(b) Excision	14
Failure to secure good functional result:	
(a) Oil arthrotomy	10
(b) Excision	14
Successful results as to cure of disease and usefulness of limb:	
(a) Oil arthrotomy	4
(b) Excision	36

Smith-Peterson has suggested that the external and internal portions of the posterior capsule be tightly fastened together with kangaroo tendon when the knee is flexed. This is a reinforcing suture, and when the knee is extended tends to keep the posterior bone surfaces from separating and to prevent the gap so often seen in the early subsequent roentgenogram as gravity tends to extend the leg. When all the sutures are tied, the skin and fat flap is closed with chromic gut in layers without drainage, and the skin with interrupted silk or silkworm-gut. The tourniquet is usually not removed until this has been done, and we do not as a rule find it necessary to tie any vessels. As soon as the bone ends are fixed by the plates or the sutures, an assistant devotes his entire attention to holding the limb in a position in which the close apposition will be maintained; and as soon as the dressing is in place a sterilized sheet iron or steel ham splint, bent previously to the determined angle, is placed beneath the limb, and with the assistant still holding, a plaster is applied from toes to groin. We hope for fairly firm callus in four weeks, we expect it in eight, and we are disappointed if the patient cannot bear some weight with artificial support in three months.

The importance of function in converting fibrous union into bony should be emphasized, cases having occurred with fibrous union for many months which rather rapidly became rigid on beginning moderate function with plaster support.

The general health of the patient often greatly improves when this focus of disease is removed. The operation is not necessarily contraindicated in the presence of visceral disease elsewhere, and we have seen such lesions improve after an excision.

With the kangaroo bundle suture, even discharging sinus cases, if not too badly secondarily infected, may be induced to become solidly united and to overcome their disease.

The occurrence and results of the cases of tuberculosis of the knee joint in adults occurring in the orthopedic clinic of the Massachusetts General Hospital since 1907 are submitted in the accompanying tables.

CONCLUSIONS

1. Tuberculosis of the knee in adults is not fully cured without operative treatment.
2. Primary synovial tuberculosis of the knee in adults exists and is frequently improved or cured by inflation of the joint with iodoform oil.
3. We have seen no permanently satisfactory function restored in cases with bone involvement.
4. Excision of the knee is the method of choice in cases with bone involvement.
5. The position of choice is from 15 to 20 degrees' flexion for ambulatory vocations, and from 35 to 40 degrees' flexion for sedentary occupations.
6. Bone plates, where the bone is firm, and the kangaroo tendon "bundle tie," for conditions in which there is much atrophy, are valuable means of internal fixation.
7. Function is important for final bony union after excision.

372 Marlboro Street—Massachusetts General Hospital.

ABSTRACT OF DISCUSSION

Dr. Melvin S. Henderson, Rochester, Minn.: The operation of dissection of the knee joint has been carried on in the Mayo Clinic for years, and we consider it one of the best types of operation that we have. Taking it all in all, it has been satisfactory, although not all the results are good.

The statement was made in the paper that the authors have never seen a case of knee-joint tuberculosis in an adult cured. I can record two such cases in which the patients got well without operation. The cases were synovial in type, clearly proved to be that by guinea-pig inoculation. Both patients have now been well for over three years. The treatment was by injection of iodoform emulsion in 10 per cent. glycerin, and not by fixation. The time of operation is important. These cases should not be operated on, but made quiescent. The age of the patient is also very important. Generally speaking, a man over 50 years of age is not a good subject for arthrodesis in tuberculosis; and many cases of this kind later require amputation. With regard to fixation, that is an important point. It depends on the social status of the patient, his occupation, etc.

I have this criticism to make of the technic described by Dr. Osgood: It appears to me to be too extensive a dissection. It seems to me important that the patient should not be subjected to a too extensive dissection, and that the operation should be quickly performed, with as little traumatism as possible. I think that some form of fixation is best, however. I had discarded it, but these statements seem to show that it is best. I have used merely one or two long nails driven through the skin below the line of incision, and up through the head and the condyles of the femur, and left projecting. At the end of three weeks I withdraw them.

In regard to the question of tuberculosis in adults, I would say that there must be a sharp differentiation between the synovial type, in which you can cure the condition by means of antiseptic solutions, and cases in which there is bone involvement, in which resection is indicated.

Dr. John Ridlon, Chicago: I should not like to have go to the general practitioners and general surgeons without a protest the statement of the apparent conviction on the part of the authors of this paper that cases of adult tuberculosis of the knee joint are not cured without operation; for I know that they are cured without operation, under prolonged immobilization and protection, the same as in children. I had the opportunity of showing such a case to Dr. Ryerson, who had doubted my statement, a year or two ago; and when he saw the patient and found how good the result was, he thought that it could not have been a case of tuberculosis. Maybe it was not; but the other knee had been excised at Johns Hopkins Hospital, the diagnosis having been concurred in by Bloodgood and Halsted of Baltimore, Gibney and Sayre of New York, and Fenger, Senn and McCarthy of Chicago.

Dr. Mark H. Rogers, Boston: This question of whether a knee recovers without operation or not in adult tuberculosis would seem to be an important one; for if such patients do recover to any great extent or in any great proportion, one does not want to do an excision in the early stage. On the other hand, if there is only probably about 1 per cent. or 2 per cent. of these cases that recover without operation, and it can be proved that they are tuberculosis, a delay in this type of case for three to five years, until there is bone destruction, will probably mean amputation and not improvement or cure. There has not yet been any record, so far as I know, of a cure by fixation. Men come to meetings and say that they have cured such cases by fixation, and that they were cases of tuberculosis; but they have not proved their results by iodoform injection. Their cure, so far as I know, has not yet been substantiated by published results; so until I see published some authentic results of careful observations, I shall still remain of the opinion that in order to get a cure, and a cure without waiting for four or five years and running the risk of having to do an amputation later, it is better to do an excision early, because there have been published authentic records of the absolute elimination of the disease by excision. If you have not obtained cures by the other methods, therefore, the earlier you do excision, the better. That is self evident. What you have to prove is that you can cure these patients without it. In a paper published last year I reviewed the records of over 100 cases. I found that, as far back as I could go, there was no record of a cure by any other method. In regard to the use of iodoform oil, I think it is too early yet to tell whether the patients so treated are cured. A good many supposedly cured cases light up later, and excision must be done. If you wait three or four years before excision, you have very poor tissue to do an excision on.

Dr. James Archer O'Reilly, St. Louis: In speaking of the diagnosis I do not think the paper mentioned the Wassermann test. That was probably an oversight on the part of the authors; because I do not believe that, with our knowledge of syphilis, any one would operate on the knee without having made a Wassermann test. In our clinic I could show several cases of similar conditions of the knee that got well under treatment without operation; but they were cases of syphilis, and not of tuberculosis. Therefore, I think it is very important that the Wassermann test be made.

Dr. Henry Keller, New York: I think it is worth while to mention that there are two classes of tuberculosis, the bovine and the human, and that there is a difference between them. When the infection is due to the human tubercle bacillus, the cases are resistant to conservative treatment, whereas cases of the bovine tuberculosis will ultimately recover, although it takes a few years. I think, therefore, that it is worth while to find out, before resorting to any operative procedure, whether we are dealing with a bovine or a human tuberculosis. If I were sure that I was dealing with bovine infection I should not excise. Such cases should be treated by persistent and prolonged immobilization of the affected joint or joints. I wish to reiterate that these two types of tuberculosis should differ in their treatment, because their prognosis and ultimate results differ.

Dr. Arthur Steindler, Iowa City, Iowa: I should like to ask Dr. Keller whether he has ever seen a case of adult tuberculosis of the bovine type, or has had any unimpeachable evidence of the existence of the bovine type in children.

Dr. Keller: Yes, sir; I have.

Dr. Walter G. Stern, Cleveland: I should like to ask Dr. Bull to explain his method of exploring the entire knee joint through "a simple lateral incision of 3 inches." I cannot see how such an incision will allow one to explore the top of the tibia, both condyles of the femur, etc., which is, of course, quite necessary in such an exploratory arthrotomy.

Dr. E. H. Arnold, New Haven, Conn.: One thing that stands out prominently in the paper is that fixation works very well in these cases, if it supplements excision or any other procedure, which emphasizes the point made by Dr. Ridlon that fixation is, after all, one of the means of cure, and will cover the bovine cases and the Wassermann-test cases, because in all of these it will prove beneficial.

Dr. F. J. Gaenslen, Milwaukee, Wis.: I should like to ask the essayist to go into the question of the results obtained by the Brackett method. We are all interested; and although he suggested that enough time may not have elapsed to allow of formulating the results, we should like to have his impressions regarding the treatment. The speaker mentioned that two weeks after the injection of iodoform oil, he began passive movements. That, I think, will impress most of us as being contrary to the principles involved in the treatment of tuberculosis; and I should like to know how he justifies that proceeding. In speaking of the tuberculin test, he referred to the local or the general reaction. I think that we should have both in all cases. One of the chief difficulties that I have had is in immobilizing the knee securely during the time the plaster is applied, whether a nail is used or not. I think that the suggestion of using a posterior splint is excellent. No mention has been made of the method that Dr. Galloway described before the American Orthopedic Association at Pittsburgh, which consists in freshening the lateral surfaces of the tibia and having periosteal bone flaps from the femur come over the denuded surface, so as to have a more secure fixation. It impressed me as a valuable help in securing early and efficient bony union.

Dr. Edwin W. Ryerson, Chicago: I have said very often that I have never seen tuberculosis of the knee get well without operation. Dr. Ridlon referred to a case that he showed me last year. It was in a woman who, many years before, had had an undoubted tuberculosis of the knee joint, which had been operated on by excision and was cured. Years later she developed what was believed to be tuberculosis of the other knee joint; but this was not proved. As

I remember, Dr. Ridlon applied a plaster-of-Paris splint from the hip joint to the ankle joint, and the knee became well at the end of six months.

Dr. John Ridlon, Chicago: The knee tuberculosis in the right knee was diagnosed by Bloodgood of Johns Hopkins, and the patient was operated on there. The tuberculosis in the left knee developed while she was still in the hospital, and the diagnosis was then made by Bloodgood and Halsted. Wassermanns did not exist at that time; roentgenograms did not exist; rabbit inoculations did not exist. It was simply the opinion of the men in Baltimore, New York and Chicago whom I mentioned that it was tuberculosis of the left knee. It was treated for three or four years, and was not cured in six months.

Dr. Edwin W. Ryerson, Chicago: I think it is only fair to state that this case was not definitely proved to be one of knee joint tuberculosis. Dr. Henderson and others have said that the synovial form may be cured in adults without excision. Of course, everything is possible, and it may be that synovial tuberculosis may be cured without operation, but can a tuberculosis that is active in the bones of the adult knee joint be cured? Personally, I have seen no such case. It seems reasonable to believe that injections of antiseptic substances into the synovial surfaces may cure synovial tuberculosis. I have long hoped that it might do so, but I have seen many cases in my clinic in which we have injected different solutions without any result whatever, except to keep the patient wearing apparatus year after year, and then, at the end of many years, convinced that the knee was not going to get well, I have lost faith in this method of treatment. It has been an almost appalling surprise to me to find how extensive the disease is in many cases. The Central States Orthopedic Club saw in one city a large series of knee joints that had been treated conservatively for five to seven years. Not one patient was well, and all had had a stiff knee for all those years that they had been under treatment; and in my opinion, none of them stands a good chance of getting well without operation.

On the other hand, we have a simple and rapid method of producing bony ankylosis in the position best suited for the individual patient. We can reasonably expect to remove a large part of the tuberculous disease, and we can rapidly make the patient able to go about without apparatus. The majority (I will not say all) of the cases of joint tuberculosis in adults, as differentiated from synovial tuberculosis, will do better, I believe, as we see an increasing number of cases, with an excision done by a competent surgeon. Whether plates or other methods of bone fixation be deemed advisable is an open question. In my hands a long plaster-of-Paris spica from waist to toes has apparently made the patients comfortable and has promoted early union.

Dr. John Dunlop, Washington, D. C.: In reply to what Ryerson has said in regard to diagnosis, and also what Dr. Ridlon said of the early diagnosis of his case, I would say that I was Dr. Bloodgood's assistant for a year and saw a great many of the pathologic knees that were excised. After the possibility of a diagnosis of chronic joint disease became known, which it was not when I worked in the laboratory, they went over all those old excisions that they had made at Johns Hopkins and found that the diagnosis of atrophic arthritis was always being made in place of the diagnosis of tuberculosis. I believe that the case that Dr. Ridlon referred to was one of atrophic arthritis, although at that time all the men in Baltimore were making the diagnosis of tuberculosis in such cases.

Dr. Edward C. Bull, Boston: There seems to have been a misunderstanding. Our statement was that we have seen no recovery of adult tuberculosis of the knee without operation—meaning to include as an operation the injection of iodoform oil. At the time of the dissection of the involved tissues no effort is made to get the diseased portion out completely, but to get out most of the synovia and diseased bone. The Wassermann, gonococcus complement fixation and tuberculin tests are made as a routine; syphilis is therefore eliminated. As to the 3-inch incision in the oil arthrotomy operation, we grant that we cannot get a complete view through this; our observations are based on what we can see and feel, the fingers being run around to break up adhesions. Passive motion is employed very conservatively at first. The capsule is quite distended under the pressure of the oil, so there is little rubbing of the synovial surfaces, and certainly no force is used in the earlier employment of passive motion. Only a very few degrees of motion are employed at first.

New and Nonofficial Remedies

The following additional article has been accepted as conforming to the rules of the Council on Pharmacy and Chemistry of the American Medical Association for admission to New and Nonofficial Remedies. A copy of the rules on which the Council bases its action will be sent on application.

W. A. Puckner, Secretary.

HALAZONE-ABBOTT.—Parasulphonedichloramidobenzoic acid.—$C_6H_4(SO_2NCl_2)COOH$-1:4.

Actions and Uses.—Halazone-Abbott is said to be a powerful disinfectant. It is said to act like chlorine, but to have the advantage of being stable in solid form. In the presence of alkali carbonate, borate and phosphate, Dakin and Dunham report that, in from thirty to sixty minutes, halazone in the proportion of 1:200,000 to 1:500,000 sterilized polluted water contaminated with such organisms as the *Bacillus coli*, *Bacillus typhosus*, *Bacillus paratyphosus* A and B, *Cholera vibrio* and *Bacillus dysenteriae*.

Dosage.—For the sterilization of water, 0.004 to 0.008 Gm. halazone, in the form of tablets containing sodium carbonate (or sodium borate) and sodium chloride, is added to 1 liter.

Manufactured by the Abbott Laboratories, Chicago. No U. S. patent or trademark.

Halazone Tablets-Abbott.—Each tablet contains halazone-Abbott 0.004 Gm., anhydrous sodium carbonate 0.004 Gm. and sodium chloride enough to make approximately 0.113 Gm.

Parasulphonedichloramidobenzoic acid was first prepared by H. D. Dakin and E. K. Dunham (Brit. Med. Jour., May 20, 1917, p. 682) under the name "Halazone." It is prepared (1) by oxidizing paratoluenesulphoneamid to parasulphoneamidobenzoic acid, and (2) chlorinating the latter.

Halazone-Abbott is a white powder having a strong odor of chlorine. It is slightly soluble in water and chloroform; insoluble in petroleum ether; soluble in glacial acetic acid, benzene, and with formation of the salt in alkali hydroxide solutions. It crystallizes in stout prisms from glacial acetic acid. The melting point of pure halazone is 213 C.

Halazone-Abbott liberates iodin from a neutral solution of sodium iodide and bromine from a neutral solution of sodium bromide.

If 15 Cc. of a saturated aqueous solution of anilin is treated with 0.05 Gm. of halazone-Abbott, the solution acquires a brownish-red color, which becomes deep blue upon supersaturation with ammonia water.

If 0.1 Gm. of halazone-Abbott is treated with a few drops of concentrated sulphuric acid, chlorine is evolved, but no blackening occurs (readily carbonizable matter).

About 0.150 Gm. of halazone-Abbott (or in the case of halazone tablets-Abbott, 30 tablets), accurately weighed, is dissolved in 100 Cc. of water and 10 Cc. of a 10 per cent. sodium hydroxide solution. Fifteen Cc. of a 10 per cent. potassium iodide solution is added, the mixture then acidified with acetic acid and titrated with tenth-normal sodium thiosulphate volumetric solution. (If the reagents used liberate iodin, the number of Cc. of tenth-normal sodium thiosulphate volumetric solution required for their decolorization should be deducted from the total volume used.) The available chlorine content of halazone-Abbott should not be higher than 26.2 per cent. or lower than 24 per cent. Each Cc. of tenth-normal thiosulphate volumetric solution is equivalent to 0.00177 Gm. of chlorine. The theoretical chlorine content of pure halazone is 26.2 per cent.

Smallpox and Vaccination in Turkey.—Smallpox is especially prevalent in the village communities. More than half the population of such places show the pock marks. The disease does not seem to have a very high mortality in Turkey, but it is the cause of innumerable cases of blindness among children, and in this respect ranks second only to gonorrheal infection. Vaccination is practiced in larger towns and cities and in the army. Only in the last instance it is systematically carried out.—A. R. Hoover, M.D., *The Survey.*

Military Medicine and Surgery

NOTES ON THE CARE OF THE CRIPPLED SOLDIER IN ENGLAND

F. C. KIDNER, U. S. A.
Captain, M. R. C., U. S. Army; Orthopedic Surgeon, Military Orthopedic Hospital, Shepherds Bush, London, England
DETROIT

The British War Office and the Royal Army Medical Corps early realized that the responsibility of the government to the wounded soldier did not end when he was discharged from hospital with his primary wounds healed, but with his usefulness more or less impaired. They appreciated that to give a man, with a badly united femur, contracted trench feet, or a paralyzed arm, a pension sufficient to keep him alive, and leave him to shift for himself, was economically unsound. They, therefore, undertook the study and perfection of methods to restore each man as nearly as possible to a state of activity and earning power which should approximate or excel that man's state before he went into the war.

The problems were and are huge ones. First to be considered were the difficulties of reconstructive surgery. Each case presented points for study which were outside the experience of the general surgeon, and had to be worked out under conditions entirely foreign to civil life. The Medical Corps of the Army had done wonders in saving life and limbs, but their skill most easily applied itself to the acute injuries. They were apt to assume permanent crippling because they had been used to seeing similar cases in civil life remain cripples. Second, the men themselves had a natural tendency to avoid prolonged hospital treatment with repeated surgical procedures. They were willing to be content with their disabilities and look forward to a life of ease, supported by their pension and helped by their friends. They could not bring themselves to see that such a life stretching ahead for many years must sooner or later become irksome. They could not foresee as did the authorities the growing discontent—first of the individual, and second of a community—which would be fostered if large numbers of healthy young men should be kept in idleness by loss of function in one or more members. The third difficulty to be considered was the provision of suitable hospitals for the accommodation of great numbers of men who must be kept under treatment for long periods of time if good results were to be obtained. Secondary to this difficulty was the provision of workshops in which men under the process of reconstruction could be taught to do useful things adapted to their ultimate loss of function. In short, the authorities were obliged to work out the details of a comprehensive scheme for the surgical, mental and physical treatment and training of enormous numbers of damaged men, of a class which we in America see occasionally in industrial surgery, in order that at the end of the war the country's man power might be as efficient, busy, and therefore happy, as ingenuity and persistence can make it. They felt that on the proper creation of such a scheme depended very largely the welfare of the nation for many years to come.

To the everlasting credit of the government, urged on by such men as Sir Alfred Keogh, the Surgeon-General, Col. Sir Robert Jones, the great orthopedic surgeon of Liverpool, Sir Walter Lawrence, King Manuel, and others, the problems just outlined have been taken up with great firmness and breadth of vision, and a splendid approach, which is constantly broadening in scope, has been made to the solution of the difficulties of rehabilitation of the crippled soldier.

It was due largely to the energy and courage of Sir Robert Jones that the War Office was made to see that surgery had not done its uttermost when a man's wounds were healed. He showed them how special training and aptitude for the work could create surgeons who would go much further than this, and acquire through long contact with chronic cases an ingenuity and patience which would enable them to take up the work where the general surgeon left off his brilliant accomplishments.[1] He showed that only men so trained could gain the best results. At first he was given his opportunity to prove his theories on only a small scale, and even then was handicapped by transfer to other duties of the men who worked under him. Gradually, however, his results began to speak for themselves, and he was given more and more a free hand. Growth was brought about by the increase in the number of beds under his control, sometimes by setting aside numbers of beds in general military hospitals and sometimes by the creation of complete reconstruction hospitals, until now there are in the British Isles something like 11,000 beds. This number is being increased rapidly and indefinitely, with a future minimum of 30,000.

It is my privilege to be stationed at the largest of these hospitals, the Military Orthopedic Hospital at Shepherds Bush, London, with its 1,100 beds and its permanent staff of five chiefs and the necessary assistants, under the orders of a major, responsible to the R. A. M. C., who acts as superintendent, disciplinarian, and business head. The hospital is divided into five services, each under the charge of one of the chiefs, and each with about 200 beds. The chiefs are all surgeons who in peace times had leanings toward orthopedics, and most of whom have served as army surgeons in the war. They have worked up to their positions through special aptitude for the work, and through periods of training in minor orthopedic positions under Sir Robert Jones. He it is who has general supervising charge of all the hospitals, and is the originator in all matters of policy. The hospital is divided into two blocks—the South and North. In the South Block are twelve wards of thirty-six beds each where the severe cases are kept. Each two wards have a head nurse and three or four nurses with voluntary women assistants. While waiting for operation or while convalescing, if able to be out of bed at all, men are transferred to the North Block, where they care for each other under the direction of two head and two or three ordinary nurses. At night the North Block is in charge of orderlies, who have certain disciplinary powers. There are also tents where many of the convalescents live. Discipline is roughly on army lines, but is complicated by the fact that it is against the law to punish any soldier in hospital except by confinement to bed, if necessary in a sort of prison ward, and by deprivation of privileges such as leave. On the whole, considering that most of the men are pretty healthy animals, they behave extremely well.

---

[1] Of late, too, it has been realized that a great proportion of the wounded men need special orthopedic care from the very first, in order that the best ultimate results may be obtained.

The hospital is thoroughly equipped with a large massage department, a gymnasium, a hydrotherapeutic plant, and an electrical department. These are interdependent and ample. The men have regular schedule cards which admit them to any or all of these departments as ordered by their surgeon. Each department is in charge of an expert in the particular form of treatment who prescribes the details, which are carried out by large numbers of trained assistants. For instance, the massage department has about twenty masseuses or masseurs, one of whom is a blinded soldier. All departments are extraordinarily well run, especially the electrical, under Capt. W. R. Bristow, whose coil for diagnostic and treatment purposes far surpasses anything I have seen. When used under his direction, electrical treatment is of real value.

As an adjunct to these departments for special treatment are large workshops—woodworking, forge, splint making, repair shops, artificial limb shop, etc. In these large numbers of the patients work regularly. Their object is fourfold: First, to keep the men busy, and in that way to take their minds off their troubles. It is well known that the victim of long standing disability is apt to become depressed and the victim of his sympathizing friends. He does not do well physically because he is in a nonreceptive psychologic state. If he works he is usually happy. Second, work provides one of the best means for passive and active motion and massage. Third, work keeps a man at his trade, or goes far to teach him a new one. Fourth, the product of the shops supplies many needs of the hospital. In the English army no man in hospital can be forced to work, except for short periods as a prescription. He must work voluntarily. Here lies the great difficulty of the curative workshop—to get a man to go to them. It has not been fully solved, and there is much to do yet in making work interesting. Gradually the men are learning the value of work, and are taking it up more willingly. The best application of work to the individual is also a hard matter, for two reasons. First, a man with an injured hand constantly tends to save that hand, and use the good one, and thus gains nothing. Second, the tendency of the business authorities of the hospital is to get as great a product from the shops as possible. Therefore, the foremen are very apt to put patients on the job they can do best, regardless of its curative value. This, too, is being solved by the appointment of a medical supervisor, who prescribes the work, and by an increasing openmindedness on the part of the authorities.

The question of long residence in hospital is also a difficult one. It is appreciated that beds in a hospital which are costly should not be blocked by men who are waiting long periods for the regeneration of nerves or the subsidence of low grade infection. Yet if the men are allowed to leave the hospital, it is often difficult to get them back. The so-called Command Depots partially solve this problem. These depots are large camps where the men are kept under military discipline, doing what little work they can, but protected from the strain of active life. They care well for certain types of cases which need no nursing. Convalescent homes, too, care for large numbers. These are rather expensive and tend to hospitalization of the patient. The Command Depots furnish some of the details of treatment, such as baths, electricity, massage etc.

From this brief statement an idea of what has been accomplished toward the regeneration of cripples in England can be obtained, and the results are excellent. Surgeons are made especially fit to deal with the men, by a well organized course of continuous training, and the trained surgeons are kept at the job.

Hospitals have been acquired by the government for the treatment of this type of case only.

The men themselves are gradually being educated to an interest in the improvement of their own condition. Education is apparently the sole means for producing this result.

Military Orthopedic Hospital, Shepherds Bush, London, England.

THE VENEREAL DISEASES

THE TREATMENT OF GONORRHEA

GENERAL CONSIDERATIONS

(Continued from page 1081)

Every patient with acute urethritis should be ordered immediately to hospital for treatment. The earlier cases are seen, the better are the chances for rapid cure and the less the dangers of posterior urethritis and the complications of gonorrhea. With gonorrhea, as with syphilis, soldiers should be encouraged to report on the slightest suspicion of trouble, and those who have been exposed should be watched for a week for manifestation of the disease. On its appearance, treatment should be instituted immediately.

The patient should be given instructions, preferably printed, on the part he must take in the conduct of his case. In all cases he must be warned of the danger of carrying the disease to his eyes, and of gonorrheal *ophthalmia*: and of the necessity of washing his hands after touching his penis or anything contaminated with his pus.

At the first examination of every case of gonorrhea, the patient should be stripped in order to permit a general survey of his condition. Note should be made of the amount of discharge and of the condition of the glans and prepuce. The presence or absence of chancre and chancroid should be determined, and the testicles should be examined for a beginning epididymitis. Then the patient should be instructed to pass his urine into two glasses.

Two-Glass Test.—The two-glass test should be made at each examination for the purpose of determining: (*a*) if the posterior urethra has been affected; (*b*) the amount of pus secreted.

The urine passed during gonorrhea appears turbid from admixture with pus, and in it are little clumps or masses of desquamated epithelium. After standing, the pus settles to the bottom of the glass and a cloud of mucus appears floating above it. As the patient goes on toward recovery, the pus disappears, but the hypersecretion of mucus continues and occasions a cloudiness of the urine, giving it a mucilaginous appearance. After the mucus disappears, the "clap-shreds" persist for months, because isolated portions of mucous membrane are not covered with epithelium and are still secreting pus.

In the two-glass test, if the anterior urethra alone is affected, the first glass of urine will be cloudy and the second glass clear; but if the posterior urethra is involved both glasses will be turbid from the presence of pus. This is accounted for by the action of the "cut-off" muscle which forms a barrier between the anterior and posterior urethra. It prevents pus in the anterior urethra from flowing back into the bladder; so that in anterior urethritis alone, the pus in front of the cut-off muscle is washed out in the first flow of urine, while the last of the urine will flow over a clean surface and remain clear; that is, the first glass will be turbid, the second clear. On the other hand, in posterior urethritis, the cut-off muscle holds back the pus, as it does the urine in the bladder, and the pus flows back into the bladder and renders all the urine turbid. When the urine in posterior urethritis is passed into two glasses, the second glass is turbid as well as the first. If it is desired to determine the condition of the anterior urethra in posterior urethritis, it can readily be done by irrigating the anterior urethra with saline solution and collecting the washings in a glass for inspection.

Microscopic Examination of Pus.—Microscopic examinations of pus are indispensable, not merely for the establishment of the diagnosis, but also for the observation of the progress and stage of the disease, for the selection of the appropriate treatment for the different stages, and finally for the purpose of determining whether the gonococci have been eliminated and the patient cured.

THE GONOCOCCUS

The gonococcus is coffeebean or kidney shaped, and usually found in diplococcus form, the flat or slightly indented side of the organisms facing each other. In pus from acute gonorrhea organisms are found both within and without the cells, crowded in masses in the leukocytes. The intracellular location of the organisms is of diagnostic importance, but is not so characteristically seen in pus from chronic cases.

The gonococcus is easily stained with methylene-blue or with most of the other anilin dyes. It is a gram-negative organism, and for the purpose of differentiation from other diplococci a Gram stain is necessary. It is quickly decolorized by Gram's method and can then be counterstained with safranin or other stain. The Gram stain does not furnish an absolutely characteristic differentiation of the gonococcus from all similar cocci, but in pus from the urethra or vagina, or from the eye in cases of acute conjunctivitis, it may be accepted as a reliable test.

For the absolute differentiation of the gonococcus, cultural methods are necessary.

In the prodromal stage when the discharge from the meatus is thin and scanty, microscopic examinations of smears shows quantities of desquamated cylindric epithelial cells and a moderate number of pus cells containing clumps of intracellular gonococci. In the ascending stage a large number of pus cells, many of them containing gonococci, and a number of free gonococci are to be seen. The stage of decline is indicated by the appearance of squamous epithelial cells, showing that the erosions have begun to cicatrize and have become covered with newly formed epithelium. Clumps of gonococci are also present, adhering to the epithelium. The pus cells have diminished in numbers and a smaller number of them contain gonococci. As the disease continues to improve, pus cells and gonococci disappear, and finally the discharge from the meatus is found to be composed only of squamous epithelium, mucus, and an occasional pus cell, without gonococci.

PROGNOSIS

The virulence of the gonococcus differs in different cases. It is often noted that when a person has chronic gonorrhea for months or years, the gonococci, wh transplanted into the tissues of another person, are not capable of producing such virulent inflammatory symptoms as when taken from a fresh case. This attenuated virulence explains the fact that in such cases the period of incubation is comparatively long, the purulent discharge is scanty, and the cases often become chronic and result in prostatitis and stricture.

Another factor which influences the prognosis in gonorrhea is the state of the patient's general health. Gonorrhea acquired in persons affected with phthisis, or who are debilitated from any cause, is apt to run a subacute, but exceedingly protracted, course. The other causes which retard recovery may be grouped as follows: (*a*) complications, posterior urethritis, prostatitis, etc.; (*b*) reinfection from a urethral gland, seminal vesicle, prostate, etc.; (*c*) lack of rest; (*d*) alcoholic indulgence; (*e*) too vigorous treatment, especially injections which are too strong or too frequently repeated; (*f*) coitus.

ANTERIOR URETHRITIS

General Management.—Acute gonorrhea should be treated on the principles that apply to other severe acute inflammatory diseases: with rest, simple diet, removal of sources of irritation, and other such measures. The patient should have rest in bed as long as the urethritis is acute or as long as there are acute complications; no other measure contributes so much to prompt and uneventful recovery He should have a bland diet from which highly seasoned or rich foods are excluded; and in very acute cases a milk diet is best. He should drink an abundance of water—eight or ten glasses daily—and no other drink except milk. Alkalies and alkaline mineral waters should not be prescribed, because an acid reaction of the urine is the best safeguard against cystitis from bacteria which find their way into the bladder; and the acidity of the patient's urine will already be greatly reduced by his free use of milk and his abstinence from meat. Throughout the disease, the bowels should be kept open with aperients, and during the very acute stage the patient should have a saline cathartic every other morning.

Dressings for the purpose of catching the discharge and keeping it from the clothing are always necessary. The best form is a loose bag, such as that which can be made by cutting off the foot of a stocking, into the bottom of which gauze can be placed to catch the pus. The bag is suspended from a waist band. In this way a free flow of pus from the urethra is encouraged and retention prevented. Constriction of the penis by dressings wrapped around it should be carefully avoided, so that there may be no interference with the return circulation. A suspensory bandage should be worn when the patient is allowed to get up, in order to relieve the sensation of dragging on the spermatic cord and perhaps to lessen the danger of epididymitis.

Oil of sandalwood is soothing and curative and should be given during the acute stages, but not copaiba or cubebs; they are serviceable only in the declining stages of gonorrhea. Sandalwood oil should be administered in capsules — dose, 0.5 to 1 c.c. (8 to 15 minims) three times a day after food. It sometimes disagrees with the digestion or causes an intense pain in the back, and then should be discontinued.

Severe Acute Urethritis.—In very severe anterior urethritis with intense reaction, profuse discharge, and great swelling and [illegible], it is good judgment to wait some sub[illegible] the symptoms before beginning injections. In the meantime the parts should be kept clean; the penis held in hot water for fifteen minutes at a time every few hours, and hot sitz baths given every three or four hours to relieve distress. If pain on urination is very distressing, it may be relieved by an injection, five minutes before urination, of 1 c.c. of 1 per cent. solution of cocain hydrochlorate or B-eucain or novocain. Sandalwood oil diminishes the pain on urination in most cases, so that the use of a local anesthetic is not often necessary.

In the same way injections should not be used for anterior urethritis in the presence of acute complications in the posterior urethra or its adnexa.

Local Treatment.—In the ascending stage of acute urethritis and in other acute cases, which do not reach the intensity suggested in the preceding paragraphs, local treatment by injection may begin at once. For treatment in this stage and as long as gonococci remain, albuminates of silver salts, such as protargol, and argyrol, should be used. The treatment may be carried out by injections with a small hand syringe or by irrigations with an uninterrupted flow of solution from a large irrigator. Both methods of treatment have their advocates; either may be used effectively. But if irrigations are used, more care is required to avoid irritation or traumatism.

For hand injection, protargol or silvol are used in strengths of from 0.5 to 2 per cent. argyrol in strength of from 2 to 4 per cent. Injections should be given three or four times daily at intervals of four to eight hours. Before injections, the patient should wash out the urethra by urinating. For these injections, an acorn-tipped syringe should be used, the tip being firmly pressed into the meatus, and the penis held under moderate tension. The injections should always be given with the utmost gentleness, and if they produce distress, their strength should be reduced. In order to be effective, a sufficient quantity of fluid must be injected to distend the anterior urethra so that a syringe of at least 15 c.c. capacity should be used. The solution must be held in the urethra for at least five minutes —better, ten.

The same treatment may be carried out by copious irrigations or urethral lavage, using a glass irrigator filled with the fluid and suspended at a height of 2 to 4 feet above the penis. The solutions used for irrigation are less concentrated than those for injection. The solutions in common use are protargol or argyrol in the strength of 1:1,000, or permanganate of potash in the strength of 1:3,000. The irrigations should be given at temperatures of from 110 to 115 F.—as hot as can comfortably be borne—and be repeated as often as four times in twenty-four hours.

Technic of Irrigations.—The patient should sit well forward on the chair and lean backward, resting his shoulders against the back of the chair. He should hold a small basin to catch the overflow of the irrigation. The irrigator tip is pressed against the meatus and the anterior urethra distended with fluid. Then by a short release of pressure of the tip a return flow is allowed. This is repeated until thorough irrigation of the anterior urethra has been obtained. If it is desired to irrigate the posterior urethra, the anterior urethra should first be washed out. Then the tip should be firmly pressed against the meatus and the anterior urethra dilated with fluid. The patient is then instructed to take a long breath and to try to urinate; this releases the cut-off muscle and the irrigating fluid flows into the bladder. The bladder is allowed to fill with fluid, but should not be distended beyond the point of comfort. After the bladder is filled, the patient empties it by urination.

The advantages of treatment by irrigations are that the surgeon is sure that the treatment is correctly applied; the discharge is rapidly reduced to a minimum; and posterior urethritis occurs less frequently than under the treatment by injections.

Stage of Decline of Gonorrhea.—Under the above methods of treatment, the acute symptoms of gonorrhea promptly disappear. If, however, treatment be discontinued at this point, even though the discharge has ceased and only a few shreds remain in the urine, a relapse is certain to occur in from two to three weeks, since a few gonococci have been left in the tissues and extensive reinfection occurs.

In about three weeks, in cases which run a favorable course under the treatment with silver albuminates, the discharge becomes watery and scant. Microscopic examination shows few or no gonococci, but many newly formed desquamated epithelial cells. The urine in the first glass is clear or slightly turbid, but contains many long mucous filaments. When the case has reached this stage, the task remains of curing the existing postgonorrheal lesions. These consist of catarrhal inflammation of the mucous membrane, erosions, periglandular infiltrations, and infiltrations of the submucous tissues. Since the albuminates of silver have the purpose only of destroying the gonococci, but exert no effect on the inflammatory processes, it is necessary at this time to treat the existing catarrh of the mucous membrane by astringent remedies.

The following are appropriate preparations for this purpose:

	gm. or c.c.	
Zinc sulphate	.60	gr. xii
Resorcin	1.25	gr. xxiv
Water	100.00	℥ iv
or		
Zinc sulphate	.20 to .60	gr. iv to xii
Phenol	.20	gr. iv
Water	100.00	℥ iv
or		
Zinc sulphate	.40	gr. x
Lead acetate	.80	gr. xx
Water	100.00	℥ iv
or		
Zinc permanganate	.05 to .10	gr. i to gr. ii
Water	100.00	℥ iv

Injections of these solutions are given once or twice daily. They are not, however, bactericidal, and should be supplemented by injections of silver albuminate, in order to get rid of the few remaining gonococci. The latter are also given twice daily, alternating with the astringent injections.

It may be repeated that these astringent injections are indicated only in the terminal stages of gonorrhea, and that they should be given neither in acute gonorrhea nor in the presence of acute complications in the posterior urethra.

Under such astringent treatment, the discharge soon stops, and the urine becomes clear and free from pus; but numerous small clap-shreds persist. When this stage is reached, a provocative irrigation of a 1:4,000 solution of silver nitrate should be given. If gonococci are still present, this causes the return of a profuse discharge, in which gonococci will be found. The occurrence of such a discharge after provocative injection necessitates a return to treatment for acute urethritis. When no relapse follows the silver nitrate irrigation and the urine is clear, but contains many shreds, dilatation of the urethra not oftener than every five days is necessary to get rid of the remaining lesions and bring the urethra back to normal. The dilatations are made with a sound large enough to distend the urethra, and if the meatus is too small to admit a 28 or 30 French sound, a meatotomy should be done. Gentle massage of the urethra should be practiced with the finger over the sound while it is lying in the urethra.

Each dilatation should be followed by a copious irrigation with a 1:10,000 silver nitrate solution, and an irrigation with the same solution should also be made on days when the dilatation is not done. A hand injection of one of the astringents may be used once or twice a day in conjunction with the irrigations.

Treatment by dilatation of the urethra and irrigation should be continued until the shreds have disappeared from the urine. In most cases this is eventually accomplished, but occasionally persons will be observed who do not respond to this treatment; these are likely to improve rapidly under a daily irrigation of potassium permanganate.

It is possible to treat gonorrhea too long, and to cause the discharge to persist by the simple irritation of injections. In such cases, there will be a secretion free from gonococci, which on squeezing will appear at the meatus as a small, transparent, glycerin-like drop, and which will cause sticking together of the meatus in the morning. In cases manifesting this condition, it is advisable to stop treatment and to allow the irritation to subside. In consequence the mucous discharge will often disappear spontaneously.

After five or six weeks of treatment, if the discharge has stopped and the urine is free from filaments, and the prostate and vesicles are not involved, treatment may be suspended. But the patient should be examined at frequent intervals for two weeks more. Cultures can advantageously be made at this time since a growth of the gonococci may be obtained even when none are seen in stained specimens. As a last precaution before discharging the patient, the urethra should be examined with a bougie à boule or urethroscope, and the condition of the prostate and seminal vesicles should be investigated to make sure that these organs are free from disease.

POSTERIOR URETHRITIS

Posterior urethritis develops as a rule after acute anterior urethritis has become subacute, that is, from the second to fourth week of infection, or later. It occurs in 40 to 80 per cent. of cases. Its occurrence is usually due to the spontaneous spread of the infection from the anterior urethra; but not infrequently the tendency to its spread is increased by a too vigorous local treatment, particularly by injudicious instrumentation. It may occur as a very severe process, or more frequently as a subacute one. In addition to the urethra, it is likely to involve the prostate and the base of the bladder, and frequently it spreads to the seminal vesicles and the epididymis.

Posterior urethritis will not escape detection, if the two-glass test is done daily as a routine measure on each patient. A turbidity of both glasses, when due to pus and not to phosphates, denotes involvement of the posterior urethra.

Severe posterior urethritis demands complete rest in bed and measures directed to the relief of the distressing symptoms. All local treatment of the urethra should be suspended. The nearer the diet approaches to a liquid or milk diet, the better. Abundant water should be taken, but diuretics should not be used, because they cause the too frequent evacuation of an already overtaxed bladder. Saline cathartics should be given every other day to reduce congestion in the pelvis. For the relief of tenesmus and pain, sitz baths of half an hour's duration, repeated several times a day, are useful. Alkalies, which favor the growth of bacteria in the bladder by rendering the urine alkaline, are contraindicated, as they are in acute urethritis. Sandalwood oil is not only curative, but soothing and gives relief in many cases. In the severe cases morphin should be given to relieve tenesmus and desire to urinate. It is best to give it in these cases in suppositories.

When other methods fail to relieve tenesmus and pain, remarkable relief is occasionally obtained by the instillation of a few drops—about ten—of a 1:500 to 1:100 solution of silver nitrate through a soft catheter or a deep urethral syringe. In the beginning this should not be stronger than 1:500, and it should not be used oftener than every two or three days. This instillation of silver nitrate in acute cases of posterior urethritis should be a last resort. It is contrary to the principles which should usually control the treatment of such cases, namely, not to introduce instruments during acute urethritis.

As a rule, the acute stage of posterior urethritis disappears promptly, and the cases pass into the condition of mild posterior urethritis, and then should be treated as such.

Treatment of Mild Posterior Urethritis.—In subacute posterior urethritis, treatment is given on principles similar to those applicable to subacute anterior urethritis. Solutions are applied to the surface, either by the injection of small quantities of concentrated solutions or by irrigations of copious quantities of dilute solutions.

In the first method, a small soft rubber catheter is introduced just beyond the cut-off muscle, and by means of a small urethral syringe about ten drops of 1:500 to 1:100 solution of silver nitrate are introduced into the posterior urethra. This is to be repeated at intervals of one or two days according to the tolerance of the case. In order to prevent immediate precipitation of the silver by the urine, the injection should be made with the bladder empty.

Irrigations are particularly applicable to the treatment of posterior urethritis. These may be given with a 100 c.c. hand syringe having an acorn tip, but they are preferably given through a gravity irrigator elevated five to six feet above the penis, according to the technic already described for irrigation. For posterior irrigations, protargol in the strength of 1:1,000 to 1:250, or silver nitrate 1:10,000 are used. Less effective, but still useful in some cases, is potassium permanganate, 1:3,000.

There is room for personal preference in selecting instillations or irrigations for the treatment of posterior urethritis. As a general statement, it may be said that copious irrigations are likely to be most useful in recent cases which are free from pain and other acute symptoms, but show rather an abundant purulent secretion; while instillations are more serviceable after the urine has cleared and only shreds remain.

As a rule, posterior urethritis is accompanied by complications in adjacent structures, and persistence depends on reinfection from these structures. Successful treatment, therefore, depends on the treatment of the complications.

THE OUTPUT OF BASES AFTER INTAKE OF ACID

The introduction of a nonoxidizable acid, such as the ordinary mineral acids, into the organism must resemble in considerable degree that condition which may result in acidosis. In order to retain its normal capacities, the body must neutralize the foreign acid and get rid of it in some way. Organic acids may be eliminated as such to a certain degree; but any noteworthy accumulation of acid products demands some compensatory elimination of base. Among the ordinarily available resources are the fixed alkalies and alkali earths of the body, as well as ammonia that is "deflected" from the usual course of nitrogenous metabolism. Severe acidosis invariably involves a depletion of the alkali reserves of the body.[1] It is well known that an increased output of ammonia attends the appearance of considerable quantities of acid in the organism, whether they are introduced experimentally or arise in metabolism.

The extent to which other bases may be eliminated is not so well known, owing, doubtless, to the greater difficulty in the analytic estimation of their output. Stehle[2] has lately undertaken a study of this question at the University of Pennsylvania. He found that administration of hydrochloric acid by mouth to dogs causes an increased excretion of calcium and magnesium as well as of sodium and potassium. But in the case of the latter pair — the alkalies — a subsequent compensatory retention makes the loss apparent rather than real. The ammonia is, however, the great factor in neutralizing acid administered in this way.

Stehle remarks that if an analogous condition holds in human diabetes, the resulting calcium loss may be something to take into consideration in the treatment of diabetic patients in whom the excretion of beta-hydroxybutyric acid has reached a significant figure. He cites an illustrative case in which there was an excretion of more than 5 kg. of this substance in the last 160 days of the patient's life. This is equivalent to 66 gm. of calcium. Such an amount, says Stehle, does not seem large when the whole calcium content of the body is considered; but it is unknown to what extent the calcium of the body must be considered inert. If the quantity is large, then 66 gm. may be quite a significant loss. The balance of calcium in diabetics is usually reported to be negative.

With the possible function of calcium as a neutralizer of acid in mind, it has been maintained that the storage of calcium is dependent on a suitable supply of alkali to the organism. Thus the assertion has been made that the addition of alkali carbonate to the food of children may change a negative calcium balance to a positive one.[3] This was believed to be due to the neutralization, by the alkali, of the acids formed in metabolism and also to a prevention of the formation in the alimentary tract of insoluble calcium soaps which cannot be utilized. The alkali was supposed to render unnecessary the withdrawal of calcium. According to a recent study by Givens and Mendel[4] at Yale University, administration of base produced no significant effect on the balance of nitrogen, calcium, magnesium and phosphorus, in dogs; nor did it decrease the urinary output of calcium in a human diabetic.

CANNING WHAT YOU CAN

Since Aesop wrote the fable of the ant and the grasshopper, and possibly before that time, it has been considered the act of the wise to store in times of ease and plenty for use in times of stress and poverty. When a nation is at war, production of many of the commodities of peace time of course diminishes. Therefore, one of the first considerations of the United States Food Administration is in the direction of food conservation and preservation — storing — the latter through canning, drying and other approved methods. On account of the increased production of food during the warm season of the year, it is necessary to save the surplus of perishables "to provide variety for the winter diet, lessen the expenditure for food, and help to simplify the growing problem of transportation."

Probably the most advantageous method of preserving foods is by canning, as this method retains the original form, color, flavor and texture of fruits and vegetables to a greater degree than do other means of preservation. In addition, such preserved foods require less preparation before serving. Of course, the initial cost of containers increases the price of canned foods over the expense of drying, brining or curing, but it is likely that the advantages of the canning method—and this includes putting up in jars, bottles, etc.—outweigh the disadvantage of the initial increased cost of containers, especially as most housewives use the same containers from year to year.

It is interesting to look back into the history and development of the canning industry. Near the end of the eighteenth century, the French government enacted, among other military measures, the offering of a bounty of 12,000 francs for an improved method of preserving foods.[1] The bounty, generous for that time, attracted many capable men. Nicholas Appert, an expert confectioner, brewer, distiller, and chef, worked on the problem from 1795 until 1804 before he attained his first success. At that time he found that by heating the product and then hermetically sealing the container, the food could be well preserved. In 1810 he published his results. He was awarded the prize, and is generally recognized as the discoverer of canning. By 1820 this method was being used in a commercial way. According to Appert's description, he packed the product in glass bottles, added sufficient water to cover, inserted the corks, and then placed the bottles in the water bath, heating them gradually for varying lengths of time, depending on the character of the food. He used glass exclusively.

In 1807 a Mr. Saddington in England had described a method of preserving essentially similar to that of Appert, but he did not claim to be the originator of the method, having obtained it while traveling in France. It was not generally understood why foods kept when heated by this method, but it was customary to ascribe the results to the exclusion of outside air after applying sufficient heat to the food. The French government appointed Guy Lussac to investigate the cause, and he reported that spoiling was a series of oxidation changes which could be prevented by the exclusion of outside air. It was only later that with the advent of bacteriology the true explanation came forth. And the honor for discovering most of the fundamental principles of bacteriology belongs also to the French master, Pasteur.

According to Bitting and Bitting, commercial canning on a small scale was begun in this country in New York in 1819, and in Boston in 1820, salmon, lobsters and oysters being packed in the former, and fruits in the latter. The firm of Underwood in Boston, which did the work at that time, has been in continuous operation since. The first cannery in Baltimore was opened in 1840, and the sardine industry at Eastport, Maine, in 1841. Appert used the glass bottle for his experiments, as did Saddington; but in 1810, Peter Durand in England took out a blanket patent on containers of almost every known material, and specifically mentioned tin. He is therefore known as the "father of the tin can." The early packers paid most attention to the preservation of fish and meat products, and the canning of fruits and vegetables was incidental. Today, or just previous to the onset of the war, there were packed annually in the United States some 3,000,000,000 cans of food, representing products of approximately 3,000 factories, and valued at millions of dollars.

Canning is the most widely used means of preserving large quantities of food, and is probably the best understood of all preserving methods. When properly performed, it yields food which is safe and hygienic and which has lost none of its palatability or nourishing qualities. In this way every householder may aid the food conservation bureau by economizing, with distinct advantage and with no detriment to himself.

WAR DIET AND METABOLISM

There seems to be little doubt that during the early period of the European war, when it seemed necessary to institute a strict economy in the distribution of food to the peoples of the countries involved, the food requirement of the population was underestimated for the physical work to be accomplished and underestimated for those who were in the period of adolescence; furthermore, that the enforcement of the food laws was placed in the hands of farmers, middlemen, and politicians, who mismanaged the situation.[1] The economy of food in the body is, in the first instance, a problem related to the need of energy and the metabolism of the offered nutrients. Even at complete rest the human organism requires energy for the performance of vital functions such as the activities of the heart and the work of the circulation and respiration, not to mention minor items of energy exchange which express themselves as tonus. Much more energy is called for as soon as external work is being done. If the food intake is inadequate it is inevitable, therefore, that the body should give up some of its stored nutrients—glycogen, fats, and last of all proteins—to maintain the performances just outlined. There can be no compromise in the matter of energy. The laws of the conservation of energy are inevitable in their incidence.

Two competent German physiologists, Professor Loewy and Zuntz[2] of Berlin, have related in a paper that has recently come to notice in this country how the early German food proclamations worked. They observed as the result of the restricted war diet that the majority of the strong and healthy men lost from 6 to 8 kg. (10 to 12 per cent.) of their earlier body weight. After the decrease a constant weight was established. The question is raised as to the cause of this decreased and then constant weight, and whether there is a relation to a lessened consumption of energy. With two people there was found a plainly evident reduction in metabolism and the decrease in consumption of energy was more marked than the accompanying loss of weight. An explanation of the low

equilibrium given is that with the decrease in body weight there is a relatively greater decrease of the active cell substance.

Evidently, any procedure which lessens the quantity of metabolizing tissues in the body may decrease the amount of energy required. An emaciated individual who is in good health will invariably exhibit a diminished metabolism. Lusk states that in starvation the fall in metabolism reaches greater proportions than does the fall in the mass of protoplasmic tissue. Thus there seems to be a specific reduction in metabolism coincident with undernutrition. But who will say that in final analysis the best measure of human performance is to be found in the most economical use of food? The newly organized Food Administration of the United States fortified by an advisory board on alimentation composed of recognized students of nutrition has not advocated that our people shall go without needed food. Indeed, we are urged to "eat wisely and well," but to choose our foods in such a way that those most needed across the seas, especially the most concentrated foods, such as wheat, beef, pork, dairy products, and sugar may be saved for export. We have for our own use an abundance of foodstuffs of other kinds—the perishables, fish, corn and other cereals—and we are asked so far as possible to substitute these for those other products of greater use abroad. The assistant secretary of agriculture has well stated the needs of the time. In time of war, he remarked, as in time of peace it is not only important, but essential that the people be well fed. Victory does not depend alone on guns and soldiers; it depends as well on the efficiency of every man, woman, and child back of the firing line. To maintain this efficiency there must be enough food and it must be so cooked and so combined as to be both palatable and nourishing. The war must be won in the kitchens and on the dining tables of America as well as in the trenches.

HUMIDITY AND HUMIDIFIERS

Our ideas respecting the physiologic action of atmospheric conditions and as to what constitutes an ideal atmospheric environment have been greatly changed in recent years. Those features of general bodily discomfort which betray themselves by unmistakable sensations—malaise, sleepiness, the flushed face, headache, disinclination to think or act, general debility—are no longer ascribed to chemical vitiation of the air, but rather to certain physical peculiarities. Carbon dioxid and unidentified organic respiratory products are at present not charged with responsibility for the unquestionably deleterious effects of certain atmospheres. Today we are inclined rather to say that "bad air" is too warm, too moist and too still. As Lee[1] has remarked, if it has not these physical features it is not harmful.

Lee has summarized the evidence of modern investigation as to what constitutes a favorable atmospheric environment by saying that when an existing external temperature is fairly comfortable to the body, an elevation of it, especially when such an elevation is accompanied by an increase of humidity, is deleterious, and the deleterious effects are more pronounced when the air is stagnant. Deleterious effects resulting from such a combination of atmospheric conditions may be obviated in some degree if the air next to the skin be put into motion, but a more effective antidote is a reduction in the temperature of the air, and this may be assisted by a reduction in its humidity. All experimentation and observation demonstrate that a moderately cool and moderately dry air in motion constitutes the most physiologically helpful aerial envelope of the body. The customary figure of 70 F. (approximately 21 C.) for the atmosphere in which most persons engage in the ordinary occupations of the living room of a dwelling, is too high; a range from 65 to 68 F. (approximately 18 to 20 C.) with not over 50 per cent. relative humidity, is undoubtedly better, but even such temperatures are too high when much physical activity occurs.

The question as to whether the atmosphere can ever become too dry for comfort or physiologic well being has not yet been satisfactorily answered. The comfort contributed by a dry atmosphere in contrast to a humid one in warm weather is unmistakable. In cold weather the moisture may be largely precipitated from the air so that it becomes extremely dry when it enters houses. This has led to the desire and the practice to moisten such air. This may be done, to some extent, by heating water in large open vessels. It has been pointed out,[2] however, that for efficient moistening of the air, either a very large evaporating surface or steam jets are required. The small open vessels or saucers on which some people rely, even when located in the air passages of a hot air furnace, have only an infinitesimal influence.

An ordinary medium-sized house requires the evaporation of not less than ten gallons of water per twenty-four hours, and much more than this according to some writers, to afford suitable conditions of moisture in cold dry weather. Various devices have been suggested and are being marketed to produce humidity in the heated house in winter months. Dean Lyon[3] of the University of Minnesota has tested four types of radiator humidifiers now on the market. The most efficient of these have evaporated no more than 1,248 grams of water (a little more than two pounds) in a day per each horizontal foot of radiator occupied by the apparatus. Lyon, therefore, states that, under the conditions of our northern winters, it will be seen that these radiator devices are practically worthless. Using the sling psychrometer he was never able to detect an increase of humidity from the use of any of them. Indeed, the best of them is no more efficient as an air moistener than one human being. The average evaporation from lungs and skin of a large laboratory class in subzero weather, and about 70 degrees F. inside temperature, was nearly two ounces per hour per person, or about 1,200 grams a day. Such information is valuable at this season when the question of maintaining humidity in house air always recurs.

THE FOOD REQUIREMENT IN INFANCY

A considerable number of data are now available respecting the energy requirement of the young infant at complete rest.[1] These establish the so-called metabolism of the individual, that is, the energy transformed in a condition of muscular repose and when absorption of food from the digestive tract is not going on. In the case of new-born infants it does not exceed forty-eight calories per kilogram of body weight per day. Children at later ages, between 2 months and 1 year, manifest a heat production equivalent to about sixty calories per kilogram per day, during sleep. Valuable as this information is, it does not suffice by itself to establish a practical basis for estimating the food requirement of the child under conditions of its customary routine. Something more is necessary than an allowance of thirty calories per pound to keep a baby alive. As Dr. Mary S. Rose expresses it, babies cannot lie quietly all the time. If they are to grow and acquire strong muscles they must have exercise, which they get by crying, kicking, pounding with their fists, and other movements. This means work, requiring a further supply of energy. A baby 5 months old has been shown to double his energy expenditure by the effort of crying. Active children really work as hard as any adult manual laborer.[2] Furthermore, a not inconsiderable quota of energy is required to meet the demands of growth of the young child.

For calculating the energy requirement in infant feeding at the present time it is customary to accept as standards the figures furnished by Rubner and Heubner as the outcome of their observations in this field. Heubner maintains that an average normal infant requires per twenty-four hours, one hundred calories per kilogram of body weight during the first three months of life, ninety calories during the second three months, and eighty or less calories during the last half of the first year of life. The greatest factor of uncertainty in such figures lies in the difficulty furnished by the unknown degree of muscular activity of an infant in the course of the day. The essential facts could be established, of course, by studies of infants in a respiratory chamber where the actual metabolism could be followed over sufficiently long periods of varied infantile activity to afford evidence of the real performance of the individuals. Experiments of this sort are attended with great difficulty in performance and inconvenience to the investigator. Dr. Talbot of Boston is to be congratulated, therefore, on his success in measuring the heat output in infants at the Nutrition Laboratory of the Carnegie Institution of Washington over successive periods so that the effects of both absolute quiet and characteristic infantile activity could be independently established and compared.[3] In babies of 2 and 6 months of age, respectively, their muscular activity increased their metabolism 67 to 70 per cent. over the basal metabolism at rest.

Talbot suggests that a rough estimate of the caloric requirements of a normal infant may be made by adding the calories used up by muscular activity to the basal metabolism. If the infant is very quiet, 15 per cent. should be added, if normally active 25 per cent., and if extremely active, about 40 per cent. To the result add 15 per cent. for energy lost in the excreta and 20 per cent for growth. Lusk[4] believes that Heubner's figure of one hundred calories per kilogram of body weight during the first month of the infant's nutrition is in excess of the requirement. He states that probably eighty calories per kilogram will be found to suffice during the whole of the first year, and that the physician should remember very definitely the lower limits. Talbot's findings tend to argue for the higher rather than the lower figure and approach the Heubner standard more closely. Talbot adds, finally, it is probable that infants fed on cow's milk, particularly on formulas containing large amounts of protein, will require even more food than infants fed on human milk, because the stimulating action of protein causes extra heat to be burned during digestion. The caloric requirements of normal infants obviously are not the same as those of the sick infant whose "basal" metabolism is higher per kilogram of body weight and who may use up additional energy because of increased restlessness from colic or discomfort, burn it up in fever, or may not absorb all the food given him, as happened in one infant who lost 20 per cent. of the food calories in the feces. Neither does it apply to the infant with a subnormal temperature, indicating depressed vital functions. These infants come under another category and require further study to answer many of the points now obscure.

Current Comment

THE COST OF MARKET MILK

The Journal has repeatedly directed attention in the past few months to the importance of maintaining unimpaired the milk supply and, if possible, increasing the production of milk in the United States in the present emergency. The reasons need not be reiterated here. The desirability of providing "a quart of milk a day" for every child is only one of the impelling circumstances for securing as much as possible of this food. In the past there have been few articles of diet which furnished so much quantitatively and qualitatively in the way of desirable nutrients in palatable form as a quart of milk at the prices current before the recent skyward tendency of costs. As there is great danger that consumption of milk will be much decreased, and since much unfavorable comment is already making itself felt, it is imperative that those vitally concerned, as is the physician in eminent degree, should understand the situation in its true light. If 10 to 15 cents per quart represented exceptionally high prices of milk before the war, it does not follow that they are in any sense exorbitant at the present time. Adequate calories can no longer be purchased at the rate of 20 cents per adult requirement per day. War means sacrifice that expresses itself in increased payment for service and materials in every direction. Economy is only one form of material sacrifice in war time. As part of its program the Connecticut Committee on Food Supply has just published studies from a survey on the cost of market milk production.[1] This deals with statistical facts rather than with exaggerated generalities bearing on the actual cost of producing milk under present conditions, that is, with the abnormal increase in prices for feed, labor and other items. After all, the dairy cow is no mysterious agency, but merely a machine, as it were, for converting one kind of food into another. The output and intake are correlated in cost, and the machine must be carefully managed. In typical communities in the Eastern United States, where the milk must be produced near to an immediate market, the cost of milk production on 178 representative dairy farms for the year ending April 30, 1917, was 5.53 cents per quart, or $2.57 per hundred pounds. In April, 1917, however, the cost was 6.29 cents per quart, or $2.92 per hundred pounds, with labor at the yearly rates. There is no profit in producing milk at the lower price. The cost per quart has advanced more rapidly than the increase in price received in the past few years. As the result of a census taken among 2,500 farmers there was shown a decrease in mature dairy stock for the year of 4.5 per cent. and an increase in young stock of 6.7 per cent. There was a net decrease of all dairy stock of 1.6 per cent. This represents the conditions *on farms remaining* in the dairy business, where, *through summer* conditions and patriotic motives, they *have been able to* nearly maintain their herd numbers. *This fall, with winter* conditions ahead, if conditions *appear to be the* same as last year, many men will probably reduce their herds. This is one of the conditions that must be averted if possible. A frank understanding of the situation will help in the impending emergency.

THE BLOOD LIPOIDS IN ANEMIA

Amid all of the conflicting views and uncertain evidences regarding the etiology or pathogenesis of the severer types of anemia, and particularly pernicious anemia, practically only one characteristic feature remains undebated, namely, the ready destruction of the red blood cells. As hemolysis has been associated in recent years with the reactions of certain lipoids, the investigators of the anemias have given consideration to the possible pathologic variations of these compounds in the blood during the course of the disease. Utterance has been given to the view that an undue amount of specially hemolytic products, such as the unsaturated fatty acids, may appear and thereby account for the disintegration. Supporters of this conception call attention to the experimental production of crises resembling those of pernicious anemia, as the result of excessive feeding of cottonseed or olive oil. Again, the lack of normally present antihemolytic blood constituents, such as cholesterol, has been postulated as the real pathogenic factor involved. There are many scattered data in medical literature bearing on the features just mentioned. Until quite recently, however, the methods for accurate study of the lipoids of the blood have been decidedly uncertain, so that comparative estimates could not easily be formed. At the Harvard Medical School, Bloor and MacPherson[1] have undertaken a timely revision of the subject in order to determine with up-to-date precision to what extent, if any, the blood lipoids may be abnormal in anemia. The outcome may be summarized by the statement that the results offer no certain evidence that abnormalities in the lipoids are responsible for the disease. Nevertheless, the low values sometimes found for cholesterol, which is an antihemolytic substance, and the reported high fat fractions, which may indicate the presence of abnormal amounts of hemolytic lipoids in the blood, are possible causative factors of which, to quote the Boston investigators, further study is desirable at this time. In view of the association of the spleen with the destruction of the red blood corpuscles, and the assumption that hyperactivity of the spleen is sometimes a cause of anemia, splenectomy has been advocated and undertaken for the relief of the condition. Without venturing any conclusion at this time regarding the efficacy of removal of the spleen in the severe anemias, we may note that the operation is followed by blood-lipoid changes. There is an increase in total fatty acids and lecithin in the corpuscles and of cholesterol in the plasma. But the results are essentially the same whether the patients have had anemia or not. In most cases of anemia the lipoid composition of the corpuscles has been found to be normal; that is, analysis has disclosed nothing in their make-up chemically to indicate any abnormal susceptibility to hemolysis.

IS THERE A FATIGUE TOXIN?

In the domain of medicine explanations of phenomena are not infrequently colored by the popular theories of the day. It has always been difficult to elucidate the chief manifestations of fatigue. These have been further complicated by the peculiar interrelations of the nervous and muscular system where the problem of fatigue is concerned. Not long after the toxin antitoxin theories began to attain a vogue in immunology, the claim was made by Weichardt, in 1904, that the chief agent in the production of fatigue is a specific substance, a fatigue toxin. A corresponding or identical substance, designated "kenotoxin," was alleged to be produced by chemical manipulation of protein materials in definite ways. However obtained, these substances were asserted to have the significant property of inducing the development of an antitoxin when they were introduced in suitable ways into the animal organism. Here then there was presented an apparent opportunity of combating fatigue by scientific methods quite as striking as the subsequent method of eliminating certain cases of laziness and languor by eradicating the hookworm from mankind. Like so many other hopes of promise this too seems to have been shattered by the outcome of critical investigation. Only recently Lee and Aronovitch[1] of the Department of Physiology at Columbia University, New York City, have subjected the specific fatigue toxin to a crucial test. They noted that when test muscles were suspended in the juice of fatigued muscles of animals their working power was diminished considerably in comparison with the contractile power of normal muscles not treated with juice. But practically the same quantitative effect was observed when the test muscles were subjected to the juice of nonfatigued muscles. The New York investigators conclude that no acutely toxic fatigue substance is produced. Weichardt's assumption of the existence of a specific fatigue toxin is therefore not sustained. It seems probable, they say, that Weichardt's animals, which were actually killed by his extreme methods of inducing fatigue, were put into a profoundly pathologic condition in which the toxic component of the protein molecule was split off. There is no reason to believe that this occurs in the normal course of fatigue.

Rodent Destruction on Ships.—Investigation of the efficiency of fumigants for the destruction of rodents on ships was made by Creel and Simpson of the Public Health Service (*Public Health Reports,* Sept. 7, 1917). Intensive trapping after fumigation was employed to determine the effectiveness of the agents used, among them being sulphur dioxid and cyanogen gas. From this investigation it is said that a fair estimate shows that cyanid gas is superior to sulphur dioxid, besides requiring shorter exposure and consequent keeping of fumigated vessels out of service. Fumigation of 182 vessels resulted in the destruction of ninety-five out of each 100 possible rodent inhabitants, while sulphur dioxid destroyed only seventy-seven of a possible 100 in a series of sixty-two vessels. The time of exposure to the sulphur was six hours, and to the cyanid gas one and one-fourth hours. It is not believed possible to obtain 100 per cent. destruction by either agent.

Medical Mobilization and the War

IN FLANDERS' FIELDS

Note.—The verses printed below appeared recently in the New York Sunday *Times,* as "By Capt. John McRae." The author, who is still in France, is Dr. John McCrae, Guelph, Canada, a brother of Dr. Thomas McCrae of Jefferson, Philadelphia. Dr. William H. Welch, in calling our attention to this poem and suggesting its reproduction in The Journal, said: "I met him a year ago in a Canadian hospital where he had charge of the medical service. He gave me the most gripping account of the hell in which fighting goes on at the front, where he had been, that I have ever heard. The verses are so simple and direct they seem to me among the best produced by the war."—The Editor.

In Flanders' Fields

In Flanders' fields the poppies blow
Between the crosses, row on row,
That mark our place, and in the sky
The larks still bravely singing fly,
Scarce heard amidst the guns below.
We are the dead. Short days ago
We lived, felt dawn, saw sunset glow,
Loved and were loved, and now we lie
In Flanders' fields.

Take up our quarrel with the foe,
To you from falling hands we throw
The torch—be yours to hold it high.
If ye break faith with us who die,
We shall not sleep though poppies grow
In Flanders' fields.

NEW ASSISTANT SURGEONS, U. S. NAVY

On September 25, Gen. W. C. Braisted, U. S. Navy, welcomed into service a class of sixty-one Navy assistant surgeons graduating from the Navy Medical School at Washington, D. C. The majority of the class are members of the Naval Reserve Medical Corps who had been ordered to the medical school for two months of intensive training.

A number of the graduates were unable to attend the graduating exercises as they were either already on active duty or were taking postgraduate work elsewhere. Some have gone to New York City for a course at the Rockefeller Institute; some to take up the study of problems appertaining to aviation; some to the laboratory of the Washington Medical School for training in technic for the detection of germs and germ carriers of infectious diseases; and others are on duties of confidential nature.

The members of the class on active duty are: Ely L. Whitehead, Evanston, Ill.; Matthew L. Carr, New York City; Dozier H. Gibbs, Alabama City, Ala.; Normal King, Waco, Texas; Robert L. Schaefer, Allentown, Pa.; Claud W. Colonna, Mappsville, Va.; Robert T. Canon, Lufkin, Texas; William J. Corcoran, Portland, Ore.; Robert N. Hedges; Ernest Larkin, Carthage, N. C.; Everett Taylor, Lancaster, S. C., and William T. Gill, Washington, D. C.

The eight at the Rockefeller Institute include: William C. Blake, Baltimore; Tracy T. Gately, New Orleans; Frank W. Ryan, Maryville, Mo.; Nelson W. Sheley, Independence, Mo.; Lyman E. Dockry, Green Bay, Wis.; William E. Morse, Annapolis, Md.; Charles H. Savage, New Orleans, and John W. Vann, Danville, Va.

The twelve with the Aviation Corps are: Victor Armstrong, Minneapolis; Clarence J. Brown, St. Louis; Henry Le R. Franklin, Benchley, Texas; Harry C. Gebhardt; Lloyd B. Greene, Augusta, Ga.; Eugene D. Hardin, Toomsuba, Miss.; Bruce F. Holding, Wake Forest, N. C.; Robert H. McMeans, Palestine, Texas; Clarence N. Meador, Chicago; Guy B. Taylor, Gibert, S. C.; William R. Taylor, New Washington, Ind., and Frank B. Wallace, Holden, Mo.

The eight in laboratory work include: John W. S. Brady, Boston; George A. Gray, Detroit; Robert P. Henderson,

NEWS OF THE CANTONMENTS

(From Our Special Correspondents)

Camp Grant, Ill.

At the opening of Camp Grant, September 5, there were more than enough physicians present to take care of the first quota of the new National Army, and shortly enough new doctors arrived to complete the medical personnel for the division. These men were under Lieut.-Col. J. M. Phalen, M. C., the division surgeon. The medical staff were distributed among the various organizations, in the line, the base hospital, a field hospital and an ambulance company.

The base hospital under Major Michie, M. C., was already in running order, in temporary quarters, which were equipped for the care of all hospital cases. Noted specialists were assigned to its staff so that all classes of disease could be skilfully treated. Several experts were assigned to the camp to make careful examination of selected cases in their specialty. The base hospital had a laboratory which made the ordinary clinical examinations and made daily examination of the water supply.

The sanitation of the camp was under Major Bailey, M. C., who ably handled the many difficult problems which presented themselves.

The camp has been unusually free from sickness, and the hospital has had a small number of cases. Most of the cases now in the wards are in men who were sick before they left their homes.

A DAY WITH THE MEDICAL OFFICER

The life of the medical officer is a pleasant although a somewhat strenuous one. Calisthenics begin at 6:10, when every one gets thoroughly warmed up by an athletic junior officer who, for the time being, has no respect for rank or figure. Well-nourished specialists with international reputations are becoming as trim as racing yachts, and, although they pant and blow in the process, they do not utter a word of complaint. Mess is from 6:30 to 7. At 7:30 all turn out for drill in marching and until 8:30 every one learns the various sanitary formation. Again the drill master is no respecter of person and woe betide the man who "forget where his right hand lieth." From 9 to noon is devoted to medical work about the hospital. Mess is at noon. At 1:30 there is instruction in delicacies of the transfer card and other Army paper work. Some of the regimental surgeons wonder, when their transfer cards come back with "diagnosis not concurred in," whether they have forgotten their art, but they usually find they have neglected to state whether the condition was acute or chronic, catarrhal or suppurative. At 2:30 most of the ward surgeons devote an hour to instructing the ward nurses. The rest of the day is devoted to finishing up odds and ends. It will be seen that a conscientious man will be busy from early morn to late at night. There is a large amount of good material at hand, and, if a man digs into it, he can get a wonderful amount of good out of it. The work is not all medical by any means and is of such varied nature that there is little chance to grow "stale." Efficient effort is well worth while, for the man who "can and does" gets the best place and is soon repaid for his efforts.

Camp Zachary Taylor

The medical situation at Camp Taylor, Dumesnil, Ky., which has been under way for about one month under the supervision of Lieut.-Col. John H. Allen, is rapidly assuming permanent form. In the camp there are at present seventeen regimental infirmaries in the care of the regimental surgeons and the base hospital. The work since the onset has been that of examining conscripts, caring for the acutely ill and isolating the unfit infectious cases before discharge from the army.

The new men after being assigned to their companies are given their physical examinations and triple typhoid and smallpox vaccine by a board of regimental surgeons. Any with outspoken defects and the doubtful ones are referred to the "Reviewing Board," an organization composed of the heads of the various departments including the specialties. Final disposition of the case remains in their hands.

The examination of the first 5 per cent. of the conscripts pointed out many defects in system both in the regimental boards as well as in the Review Board, which when corrected made the examination of the second 40 per cent. move much more quickly and efficiently.

Many interesting medical conditions have been found which it is hoped we will have the opportunity to dilate upon at another time, several of these cases being in the base hospital at present.

BASE HOSPITAL

The base hospital has been in permanent quarters for two and one-half weeks and is occupying eight of the thirty-two wards. There are at present 216 patients in the hospital, divided as follows: medical, 23; surgical, 24; genito-urinary, 103; ophthalmologic, 53; neuropsychiatric, 13. The large number of genito-urinary patients is composed mostly of men with active syphilis, who are isolated before being discharged from the army.

The fifty-three ophthalmologic cases are trachoma, mainly from the mountain regions of Kentucky, and have been the source of much interest. Major John McMullen, U. S. Public Health Service, came last week to see these patients, and gave an interesting clinic on them. Major McMullen, formerly at Ellis Island, is at present in charge of the trachoma work in Eastern Kentucky, Virginia, West Virginia and Tennessee and is well qualified to speak on this subject. As a result of this large number of cases of trachoma, a general survey of the camp in the hands of experts is being contemplated.

SOCIAL

Major Nelson M. Black, M. R. C., from the Surgeon General's Office, spent part of the week visiting the camp. He addressed the staff of the base hospital on "Surgery of the Head," the specialty to which he is detailed.

Major John Ridlon, M. R. C., supervising orthopedic surgeon, was a new arrival this week. He will spend a few days, giving a course of lectures on his specialty and then continue on his circuit. Major Ridlon, who is honorary professor of orthopedic surgery at Northwestern University, is the fourth Chicago major at the base hospital. The other three are: Major William H. Wilder, M. R. C., professor of ophthalmology at Rush Medical College; Major F. Menge, M. R. C., professor of otolaryngology at Northwestern University, and Major Walter W. Hamburger, M. R. C., associate professor of medicine at Rush Medical College.

Camp Lee, Petersburg, Va.

Every one who comes to Camp Lee, Va., soon realizes that this is historical ground, for a little walk along the western part of the camp reveals rifle pits and in the woods along the edge of the camp are trenches and redoubts which were made by the federal forces during the famous siege of Petersburg in 1864. The base hospital is located in this area and in digging the foundation many interesting Civil War relics were found. Although many boys earned their pocket money by picking up lead from the battlefields, a little search brings to light a "minie" ball or shell fragment. About 2 miles to the west of the camp is a ridge where the Confederate works were built and there is still present the deep "crater" formed by the explosion of a mine on July 30, 1864. The mine was dug and planted by a regiment of Pennsylvanians and was the first mine exploded in war.

The camp was named after Gen. Robert E. Lee, who was in command of the Confederate forces during the defense of Petersburg. Today Pennsylvanians and Virginians, with West Virginians as well, instead of being antagonists, are drilling as brothers on this battleground.

Some of the barracks are built on the Prince George Court House Road traveled over by LaFayette and Virginia soldiers during the Revolutionary War and Yorktown is but 30 miles away.

PERSONNEL

Work was begun at the camp in June. The forest was cleared and buildings commenced. Major Henry P. Carter, M. C., U. S. Army, was appointed sanitary inspector and began his work the middle of July. Major Carter was well fitted for the work as he had just returned from three years' service in the Panama zone, where he had served as health officer of Ancon and Panama. In the latter part of July Capt. Hugh T. Nelson, M. R. C., Charlottesville, Va.; First Lieut. William F. Merchant, M. R. C., health officer of Manassas, Va., and First Lieut. Harry R. Seelinger, M. R. C., Norfolk, Va., were assigned to assist Major Carter. Under Major Carter's directions all swamp and marshy areas have been ditched and oiled, so that now instead of many anopheles mosquitoes there are none and only an occasional larva is found whose ambitions are promptly drowned by a dose of crude oil.

Major Ferdinand Schmitter, M. C., U. S. Army, came early in August to be commanding officer of the base hospital and acted as chief surgeon until the permanent assignment of the division surgeon. Major Schmitter has had a wide experience in administration and examination of recruits and has been of great assistance in directing the examination of recruits.

Lieut.-Col. T. L. Rhoads, M. C., U. S. Army, was assigned as division surgeon early in September. Colonel Rhoads brought with him a wide experience in administrative work and is admirably equipped for the post. He had been specially selected by President Taft to represent the government in handling the relief work after the flood at Dayton, Ohio. Colonel Rhoads is well known in the Army and has served as operating, administrator and also in a sanitary capacity in Texas in 1916.

A number of medical officers were assigned to the division and base hospital before the arrival of the first quota. They were temporarily quartered in barracks pending the completion of the base hospital. While in the barracks they were constantly entertained by the negro stories told by Major Joseph W. Hope, M. R. C., Hampton, Va., and First Lieut. Isaac M. Goldman, M. R. C., Richmond, Va. Now that the hospital is nearly finished the officers and the patients under treatment have moved in. Medical supplies have been furnished by First Lieut. Romanus A. LaGrinder, S. C., who has had nineteen years' experience in Hospital Corps work, and is in charge of the medical supply depot.

Capt. Elliott B. Edie, M. R. C., came from Fort Oglethorpe the last of August with the personnel of a field hospital, and First Lieut. Burr Ferguson with the personnel of an ambulance company, whose organizations had been through a course of training under Colonel Page. The medical organization has been increased by the arrival of an ambulance company under the command of Capt. Charles L. Scott, M. R. C., Raleigh, N. C., organized by the Raleigh Red Cross. The Richmond Red Cross has also sent an ambulance company under the command of First Lieut. Charles H. Lewis, M. R. C.

EARLY EXAMINATIONS

The arrival of the second quota of the draft the last of September created great activity among the medical officers. Physical examinations, vaccinations, sick call and paper work kept them busy and troubled with many new duties. The work was well done and soon finished. Recruits for rejection and doubtful cases were referred to specialists at the base hospital. Special examinations for heart and lung cases were put under the direction of Major Lawrence Litchfield, M. R. C., Pittsburg, Va.; surgical conditions, First Lieut. William L. Peple, Richmond, Va.; genito-urinary, Capt. J. Bayard Clark, M. R. C., New York City; eye, ear, nose and throat, Capt. Llewellyn E. Hetrick, M. R. C., New York City, assisted by Capt. Lawrence Thomas, Latrobe, Pa. Medical work is now progressing smoothly and sanitary conditions are excellent. Petersburg furnished the camp with a safe water supply, drainage is excellent, the camp is well sewered, buildings are all screened against flies, and the health of the men is excellent. The sick rate is far lower than the sick rate of the Army in 1916.

The Patriotism of Sioux City

Dr. John W. Shuman of Sioux City, Iowa, writes: "I note in The Journal, Sept. 29, 1917, page 1090, under 'Medical Patriots of Rochester, N. Y.,' 13.1 per cent. of the physicians of that city have enlisted. I drop you this line to let you know that Sioux City has Rochester beaten on the percentage basis. Here is Sioux City's bit to date: the population is 65,000, there are 100 physicians practicing in the city, twenty-one of whom have been commissioned in the Army."

Exemption Asked for Dental Students

A committee consisting of Arthur D. Black, Chicago, chairman; H. E. Friesell, Pittsburgh; W. H. G. Logan, Chicago, and F. D. Casto, Cleveland, has submitted to the Provost-Marshal's Office arguments for the exemption of drafted dental students. The committee points out that there is no legal obstacle to the issuance of an order for dental students similar to that issued for medical students; that dental schools will lose a large number of students by the draft and, owing to the fact that all dental schools have extended their courses from three to four years this fall, there will be no graduating classes in 1920. It is stated that the supply of dental students is already less than the demand and that the present ratio of Army dentists is inadequate. This ratio calls for one dentist to each 1,000 men, which corresponds to a provision of one hour of dental service over six months for each enlisted man. It is argued that there should be at least one dentist for each 500 men in the Army. The committee points out that dentistry is closely related to the practice of medicine, that face and head wounds constitute 20 per cent. of the injuries in the war zone, and that the services of none of the various medical specialists are more important to the welfare of the Army than those of the dentist.

Food Division in Surgeon-General's Office

Major-Gen. William C. Gorgas, Surgeon-General, U. S. Army, has organized a division for safeguarding the food supply of the Army. This work is to be carried on in cooperation with the Quartermaster Corps and will include a food survey of each camp conducted by specialists in nutrition, together with inspection of food received for soldiers' rations and study of methods of preparation. It is desired not only to prevent sickness through improper food but also to recommend changes to provide more healthful and appetizing meals. About sixty commissioned officers will be engaged in the work of making food surveys at the camps, with about twice their number of enlisted men to assist in the work. Major John R. Murlin, formerly of Cornell University Medical College, will act as director.

Recommendations for Control of Venereal Disease in Michigan

The commission recently appointed to present recommendations for control of venereal disease as presented by the mobilization of the new army in Michigan has reported to Governor A. E. Sleeper, that at a meeting held in Lansing, September 28, the subject was carefully considered, with the view of presenting to the War Board a practical program designed to control and minimize this menace.

The commission stated that it does not harbor the illusion that venereal disease can be eradicated from the state by any program it might suggest. However, it is the unanimous opinion of its members that a great deal can be done to reduce the danger of venereal infection to the soldiers and to the civil population. It is obviously very necessary at the outset to secure the cooperation of the military authorities in any proposed plan of action.

The following general plan is recommended as the most practical means of securing the desired results:

1. The sources of infection to be located in every possible way.

By securing the cooperation of the military medical authorities in the reporting of cases from which soldiers have acquired infection.

The appointment by the state board of health of a special medical inspector to be stationed at Battle Creek, and the detailing of inspectors to other points if necessary.

Cooperation with the local health authorities of various communities in the state.

Suggestions to the cities of Battle Creek and Kalamazoo of the desirability of securing the services of full-time health officers.

Furnishing, by the state, of free laboratory tests for venereal diseases.

2. Segregation of infected persons.

Infected soldiers to be segregated in camp, by military authority.

Infected women to be segregated in detention hospitals or by house quarantine, if necessary.

Hospital facilities at Detroit and Ann Arbor being now available, the commission recommends the use of these hospitals until further arrangements can be made.

3. The treatment of infected persons.

Soldiers to be treated in camp by the military medical authorities.

Infected cases in the civil population to be cared for in the segregation hospitals above mentioned and in free clinics to be established at various points in the state.

4. The supervision of cured or arrested cases.

By paid social workers in each of the several communities near the encampment.

5. By enlargement of the protected zone.

The military authorities to be requested to extend the zones under authority of the act of May 18, 1917.

6. By a campaign of education.

In the military camps, through cooperation with the Medical Corps of the Army.

In communities throughout the state, under the auspices of the state board of health.

Cantonment and Camp Sites

Perhaps no words have been more used recently in questions of military operations in this country than the words "cantonment" and "camps." According to the Field Service Regulations:

> When troops are sheltered under canvas, they are in camp. When resting on the ground without shelter, they are in bivouac. When occupying buildings in towns or villages, or huts specially erected, they are in cantonment.
>
> Cantonments often develop through improvement of camps—huts or temporary buildings taking the place of tents.

Paragraph 236 of the Field Service Regulations of United States Army concerns shelter in the service of the interior. In itself it is a lesson in hygiene and sanitation. It says:

> In mobilization and concentration camps, troops are sheltered under canvas or in temporary barracks, and proper provision is made for their health, comfort, and instruction. As a rule, such camps or cantonments should fulfil the following conditions:
>
> 1. The grounds should be easily drained, naturally healthful, large enough for depots, corrals, hospitals, etc., and the encampment of the troops without crowding, and with ample space for exercise and instruction.
>
> 2. The water supply should be excellent and abundant and not liable to contamination from any source.
>
> 3. There should be ample railroad and switching facilities and suitable arrangements for loading and unloading, as the fundamental reasons for the mobilization or concentration will be defeated if ample rail or water facilities are not available to promptly receive and dispatch troops and supplies.
>
> 4. All parts of the camp should be readily accessible by good wagon roads.
>
> All arrangements for the accommodation and supply of the troops should be completed before their arrival by the permanent camp personnel sent ahead for the purpose. Camps are laid out so as to preserve the integrity of units, the headquarters of each being centrally or conveniently located with respect to its troops; tents are pitched and aligned, kitchens equipped, water and fuel supply arranged, latrines prepared, hospitals erected, and arrangements made for ample mail, telegraph, and telephone service. The general headquarters should be centrally located and connected by wire with the principal subordinate headquarters. Depots and storehouses are placed at railroad sidings and the hospitals near the railroad station. Trains are placed so as to interfere as little as possible with the comfort and cleanliness of the troops.
>
> No individuals, troops, or trains of organizations temporarily present should be attached to the permanent camp personnel, if it can be avoided. It is the function of the permanent camp personnel to operate depots, hospitals, to maintain camp telephone and telegraph lines, etc. The troops temporarily present must be in constant readiness to move.

August 18, the Field Service Regulations were modified, and this paragraph was added:

> 5. Boards for the selection of permanent or semipermanent cantonment sites will include in their membership an officer of the Medical Corps.
>
> All questions of sanitation and hygiene, relating to building construction, water supply, drainage, or sewage disposal for such cantonments, on which the board is not unanimously agreed, will be referred to the department commander for final action.

Orders to Officers of the Medical Corps

Lieut.-Col. J. C. Gregory, M. C., to Fort Benjamin Harrison, Ind., training camp, as instructor.

Par. 12, S. O. 210, Sept. 10, 1917, War D., relating to Major L. P. Williamson, M. C., is revoked.

Officers of M. C. to duty as follows: Col. T. J. Kirkpatrick to Fort Oglethorpe as surgeon; Lieut.-Col. F. C. Baker to Fort Oglethorpe, medical officers' training camp, as camp surgeon; Major J. W. Meehan from duty in Canal Zone to Syracuse, N. Y.

The following appointments in the Medical Corps are announced, to rank from the dates named, all in 1917: To be first lieutenants: First Lieuts. J. P. Kelly, Aug. 20; E. J. Farrow, Aug. 21; H. L. Freeland, Aug. 22; W. M. Archer, Jr., Aug. 23, and H. F. Philips, Aug. 24.

The leave granted Major F. N. Chilton, M. C., on account of sickness, is extended one month.

First Lieut. A. J. Canning, M. C., from Corregidor Island to Manila for duty.

Major P. L. Freeman, M. C., to duty at Fort Myer, Va.

Major E. G. Huber, M. C., to South Bend, Ind., for investigating the report of typhoid fever at that place.

Orders to Contract Surgeons

CALIFORNIA

To Camp Kearny, Linda Vista, Calif., from Arcadia, Calif., for duty as a member of a board of medical officers for the special examination of the troops for tuberculosis, Drs. Charles C. Browning, J. E. Fahy, Leon Shulman, Los Angeles; Lewis D. Remington, Monrovia.

CONNECTICUT

To Walter Reed General Hospital, Tacoma Park, D. C., and report to commanding officer for special instruction in tuberculosis examinations, Drs. George H. Jennings, Jewett City; Hugh F. Keating, New Haven.

DISTRICT OF COLUMBIA

To Walter Reed General Hospital, Tacoma Park, D. C., for duty, Dr. Francis S. Echols, Washington.

To his home from duty at Camp Lee, Petersburg, Va., Dr. Thomas A. Claytor, Washington.

ILLINOIS

To Walter Reed General Hospital, Tacoma Park, D. C., and report in person to commanding officer for special instruction in tuberculosis examinations, Dr. James S. Rankin, De Kalb.

LOUISIANA

To their homes from duty, Drs. Robert Bernhard, Harold J. Gondolf, James C. Cole, Edmund Moss, New Orleans; Robert A. Strong, Pass Christian.

MASSACHUSETTS

To his home from duty at Boston, Mass., Dr. Edward W. Taylor, Boston.

MISSOURI

To his home from Chickamauga Park, Ga., Dr. Scott P. Child, Kansas City.

NEW YORK

To Camp Sevier, Greenville, S. C., for the purpose of making examinations in his specialty and on completion of this work to return to his home, Dr. Robert J. Carlisle, New York City.

To Walter Reed General Hospital, Takoma Park, D. C., and report in person to commanding officer for special instruction in tuberculosis examinations, Drs. Leonard P. Sprague, Chateaugay; Percival F. Dalphin, Malone.

RHODE ISLAND

To Walter Reed General Hospital, Takoma Park, D. C., and report in person to commanding officer for special instruction in tuberculosis examinations, Dr. Jay Perkins, Providence.

TEXAS

To his home from duty at Leon Springs, Dr. Charles H. Carter, Smithville.

Orders to Officers of the Medical Reserve Corps

ALABAMA

To Army Medical School, Washington, D. C., for instruction, Lieut. Clarence C. Elebash, Selma.

To Camp Gordon, Atlanta, Ga., for duty as tuberculosis specialist and assistant to the Army Medical Staff, Capt. Cabot Lull, Jr., Birmingham.

To Camp Sheridan, Montgomery, Ala., for duty, Lieut. James R. Haigler, Montgomery.

To Phipps Clinic, Baltimore, Md., for a course of study in his specialty, Lieut. Robert H. Howard, Tuskegee.

To Post Graduate Hospital, New York, N. Y., for a course in orthopedics and on completion of this course to proceed to Boston, Mass., for further instruction, Capt. Paul L. Cocke, Birmingham.

ARIZONA

To Fort Benjamin Harrison for a course of instruction, Lieut. William A. Kinsley, Tuscon.

To Fort Benjamin Harrison for instruction, Lieut. Charles F. Thomas, Fordyce.

To Fort Des Moines, Ia., for instruction, Lieut. George W. Antoine, Prescott.

CALIFORNIA

To Camp Kearny, Linda Vista, Calif., from Arcadia, Calif., for duty as a member of a board of Medical Officers for special examination of the troops for tuberculosis, Capt. Ralph L. Byrne, Los Angeles.

To Camp Macarthur, Waco, Tex., from Psychopathic Hospital, Ann Arbor, Mich., to make examinations in his specialty, Lieut. William H. Holmes, Pomona.

To Fort Benjamin Harrison for instruction, Lieut. Clarence H. White, Los Angeles.

To Fort Des Moines, Ia., for instruction, Lieut. Claudius Ballard, Los Angeles.

CANAL ZONE

Par. 55, War Dept., Aug. 27, 1917, as related to Major Thomas D. Woodson, Corozal, modified so as to assign him to permanent duty in the office of the Surgeon General.

COLORADO

To Camp Dodge, Des Moines, Ia., for duty with Red Cross Ambulance Co., No. 30, Lieut. Jesse D. Wilson, Ideal.

CONNECTICUT

To Army Medical School, Washington, D. C., for instruction, Lieuts. Joseph A. Higgins, Manchester; Charles A. Jenkins, Willimantic.

To Camp Jackson, Columbia, S. C., from Walter Reed General Hospital, for duty as tuberculosis specialist and assistant to the Army Medical Staff, Lieut. Wilson Pendleton, Wallingford.

To Fort Benjamin Harrison, for a course of instruction, Capts. Thomas F. Scanlon, Georgetown; from Walter Reed General Hospital, for duty as instructor in tuberculosis examinations, Henry F. Stoll, Hartford.

DISTRICT OF COLUMBIA

To Camp Mills, Garden City, L. I., for inspection and on completion of this duty to return to his proper station, Major General William C. Gorgas, Washington.

FLORIDA

To Army Medical School, Washington, D. C., for instruction, Lieut. James E. Pennington, Wellborn.

GEORGIA

To Fort Benjamin Harrison for instruction, Lieut. Charles J. Woods, Darien.

To Fort Des Moines, Ia., for instruction, Lieut. Frank P. Raiford, Atlanta.

To home from Fort Oglethorpe on account of being physically disqualified, Lieuts. John W. Oden, and Thomas E. Oden, Blackshear.

ILLINOIS

To Army Medical School, Washington, D. C., for instruction, Lieuts. Marcus H. Hobart, Chicago; Guy V. Forney, Walnut.

To Camp Doniphan, Ft. Sill, Okla., from Psychopathic Hospital, Ann Arbor, Mich., to make examinations in his specialty, Lieut. Harry R. Hoffman, Chicago.

To Camp Grant, Rockford, Ill., for duty, Capt. French S. Cary, Chicago.

To Camp Greenleaf, Ft. Oglethorpe, for instruction, Capt. Thomas S. Crowe, Chicago; Lieut. Thomas W. Toler, Astoria.

To Fort Benjamin Harrison for instruction, Major John W. Turner, Oak Forest; Capts. Roy H. Garm, Beardstown; Lorin C. Collins, Chicago; Henry G. G. Schmidt, Elgin; Bernard M. Conley, Wilmette; Lieuts. William C. Cotton, Benson, Ill.; Robert A. Noble, Bloomington, Ill.; Henry S. Zimmerman, Cameron, Ill.; Everett P. Coleman, Canton, Ill.; Ira McKinney, Champaign, Ill.; Norman S. Starr, Charleston, Ill.; Walter E. Bourque, Chicago; Maurice W. K. Byrne, Chicago; Mandel A. I. Cohen, Chicago; William De Boer, Chicago; Karl J. Henrichsen, Chicago; Harry T. Isacowitz, Chicago; Robert R. Kirkpatrick, Chicago; Anthony J. Linowiecki, Chicago; Gilbert M. Loewe, Chicago; Gottlieb A. Lurie, Chicago; Harry G. Martin, Chicago; Frank R. Maurer, Chicago; Clarence McClellan, Chicago; Guy M. McLean, Chicago; Theodore E. Miller, Chicago; Eugene A. Moulton, Chicago; David V. Omens, Chicago; Hans A. Paulsen, Chicago; Ralph W. Petersen, Chicago; Louis W. Pijan, Chicago; Irving A. Porges, Chicago; Carl G. Rydin, Chicago; Samuel Sullivan, Chicago; George C. Tallerday, Jr., Chicago; Adolph M. Teixler, Chicago; George B. Wallace, Chicago; Warren O. Wheelock, Chicago; Theodore M. Wiersen, Chicago; Edward Buckman, Chicago; George W. Cusick, Chicago; Louis Savitsky, Cicero, Ill.; Frank A. Stockdale, Coal City, Ill.; James R. Tweedy, Cobden, Ill.; Raymond E. Hillmer, Crescent City, Ill.; Charles J. Davis, Deerfield, Ill.; Walter A. Day, Fosterburg, Ill.; Clair L. Stealy, Freeport, Ill.; Frederick C. Vogt, Gillespie, Ill.; Osmon C. Church, Glen Carbon, Ill.; Harry D. Wiley, Glencoe, Ill.; Paul G. Capps, Herrin, Ill.; Elza F. Tate, Homer, Ill.; Oscar George Culli, Ina, Ill.; Augustus S. Hunt, Jerseyville, Ill.; Hayden F. Threlkfeld, Jerseyville, Ill.; Joel E. Toothaker, Ladd, Ill.; William E. Mercer, Liberty, Ill.; Ralph E. Kleckner, Mattoon, Ill.; George C. Shockey, Melrose Park, Ill.; Anson Leroy Nickerson, Momence, Ill.; Charles J. Poole, Mt. Vernon, Ill.; Ralph S. Sabine, Murphysboro, Ill.; Raymond C. Gillogly, Newmann, Ill.; Marshall Wallis, Normal, Ill.; Arthur K. Spiering, Oak Park, Ill.; Ralph G. Cressman, Oglesby, Ill.; Corwin S. Mayes, Olliopolis, Ill.; John O. Gaston, Park Ridge, Ill.; Harry E. Brown, Peoria, Ill.; James F. Hilgenberg, Pesotum, Ill.; Loran E. Orr, Petersburg, Ill.; Alonzo B. Middleton, Pontiac, Ill.; Orin R. Wakefield, Princton, Ill.; Harry S. Seiwell, Quincy, Ill.; William E. Park, Rockford, Ill.; Robert B. Miller, Rock Island, Ill.; Ford C. Walsh, Rock Island, Ill.; Benjamin D. Mosher, Serena, Ill.; William D. Chapman, Silvis, Ill.; Clausen M. Wilmot, Speer, Ill.; Ora M. Williamson, Sullivan, Ill.; Asa L. T. Williams, Vandalia, Ill.; Thomas W. Morgan, Virden, Ill.; Clarence W. Chapin, Weldon, Ill.

To Ft. Des Moines, Ia., and report to the commanding officer of that post for duty as chief of the medical service at the base hospital, Capt. Herbert H. Frothingham, Chicago.

To Fort Riley, for duty at Base Hospital, Lieut. Edmon E. Richardson, Mattoon.

To Fort Sheridan, Ill., from duty at Camp Grant, and report for duty to the commanding general, Capt. Theodore S. Proxmire, Lake Forest.

To Washington, D. C., St. Elizabeth Hospital for course of study in his specialty, Lieut. Harry A. Durkin, Peoria.

To his home from Fort Oglethorpe on account of being physically disqualified, Lieut. James A. Emmons, Pinkstaff.

Par. 26, War Dept., July 30, 1917, as relates to Lieut. George D. Guca, Chicago, is revoked.

INDIANA

To Boston, Mass., for a course in orthopedics and on completion of this course to proceed to Post Graduate Hospital, New York, for further instruction, Lieut. Louis A. Bolling, Attica.

To Fort Benjamin Harrison for instruction, Lieuts. Aaron M. Winklepleck, Alfordsville, Ind.; George C. Taylor, Clay Pool, Ind.; Harry H. Ward, Coalmont, Ind.; Homer H. Tallman, Culver, Ind.; Walter W. Wright, Edinburg, Ind.; Warren Wilburn Hewins, Evansville; Reavill M. Walden, Evansville; Ben Webster, Kingsbury, Ind.; Frederick A. Henderson, Kokomo, Ind.; Byron J. Peters, Kokomo, Ind.; Manford M. Clapper, Lafayette, Ind.; Carlos C. Rozelle, La Grange, Ind.; Benjamin T. Teaford, Lanesville, Ind.; James O'Dell Rhea, Linden, Ind.; Otto H. Swantusch, Metz, Ind.; Irving A. Whitlach, Milan, Ind.; Lloyd H. Simmons, Millersburg, Ind.; Earl L. Waite, Rochester, Ind.; Ora L. McCoy, Romney, Ind.; Tony E. Hunter, Versalles, Ind.; Espy K. Schurtz, Waterloo, Ind.

So much of Par. 34, War Dept., Aug. 30, 1917, as relates to Lieut. Lawrence E. Jewett, Wabash, is revoked.

IOWA

To Army Medical School, Washington, D. C., for instruction, Lieuts. William H. Jenks, Jr., Tipton.

To Fort Benjamin Harrison for instruction, Lieuts. Robert S. Moth, Council Bluffs; Robert B. Stephenson, Libertyville; John C. Crane, Varina.

To Washington, D. C., St. Elizabeth Hospital, for course of study in his specialty, Lieut. Percy B. Battey, Independence.

Honorably discharged from Fort Riley, Lieut. Corvus C. Lang, Altoona.

KANSAS

To Camp Pike, Little Rock, Ark., for duty with Ambulance Co. No. 44, Lieut. David C. Munford, Montezuma.

To Fort Benjamin Harrison for a course of instruction, Lieut. Paul C. Carson, Ashland.

To Fort Leavenworth, Kan., for duty as ophthalmologist and otolaryngologist in the Post Hospital, Capt. John L. Fryer, National Military Home.

KENTUCKY

To Army Medical School, Washington, D. C., for instruction, Lieuts. Floyd K. Foley, Central City; Nona B. Ellis, Lynnville.

To Fort Des Moines, Ia., for instruction, Lieut. William H. Smith, Louisville.

To Fort Riley, for duty as Chief of the Surgical Service, Capt. Frank T. Fort, Louisville.

To Phipps Clinic, Baltimore, Md., for a course of study in his specialty, Capt. Walter A. Lackey, Hopkinsville.

Honorably discharged from Fort Riley, Capt. William A. Poole, Henderson.

LOUISIANA

To Army Medical School, Washington, D. C., for instruction, Lieut. Henry T. Simon, New Orleans.

To Fort Des Moines, Ia., for instruction, Lieut. Aaron W. Brazier, Slidell.

Letter from War Dept., Sept. 18, 1917, No. 4249, as relates to Lieut. Neely M. Palmer, Leesville, is revoked.

MAINE

To Fort Benjamin Harrison for instruction, Lieuts. Henry K. Stinson, Augusta; Ralph W. Wakefield, Bar Harbor; William J. Young, Orono; Edward L. Sollima, Portland; Preston W. Whitaker, Unitz; Bernard A. Bailey, Wiscasset.

MARYLAND

To Camp Meade, Annapolis Jct., Md., for duty as tuberculosis specialist and assistant to the Army Medical Staff, Capt. Gordon Wilson, Baltimore.

To Fort Benjamin Harrison for instruction, Lieut. Frederick W. Wastell, Jr., Harbor Beach.

To Walter Reed General Hospital, from Fort Myer, Va., for a course of instruction in tuberculosis examinations, Lieut. Charles W. Rauschenbach, Baltimore.

To Washington, D. C., and report in person to the Surgeon General of the Army for duty in the section of surgery of the head, Major James Bordley, Jr., Baltimore.

Par. 80, War Dept., June 2, 1917, so much as relates to Major John A. Clark, Takoma Park, is revoked.

MASSACHUSETTS

To Boston State Hospital, Boston, Mass., for a course of study in their specialty, Lieuts. William T. Rumage, Arlington; George B. Wilbur, Newton.

To Camp Logan, Houston, Tex., from Psychopathic Hospital, Boston, Mass., to make examinations in his specialty; Lieut. Raoul G. Provost, New Bedford.

To Camp Meade, Annapolis Jct., Md., from Fort Benjamin Harrison and report in person to the commanding general 79th Div., for duty with the 23d Engrs., Capt. Timothy F. Goulding, Boston.

To Fort Benjamin Harrison for a course of instruction, Capts. Carlisle Reed, Boston; Charles Dudley, Kingston; Erik St. John Johnson, New Bedford; Charles L. Upton, Shelburne Falls; Lieuts. Louis J. Ullian, Sterling E. Wilhoit, Boston; Henry L. Davis, Lynn; Ridgely F. Hanscom, Newton; John A. Sullivan, Pittsfield; George W. Tully, Southbridge; William L. Connery, Springfield.

To Washington, D. C., and report in person to the Surgeon-General of the Army, for duty in connection with the section surgery of the head, Major Allen Greenwood, Boston.

Par. 204, War Dept., Aug. 22, 1917, as relates to Lieut. William J. McDonald, Brookline, modified so as to relieve him from duty at Fort Snelling, Minn.

MICHIGAN

To Army Medical School, Washington, D. C., for instruction, Lieut. James G. Carr, Detroit.

To Camp Beauregard, Alexandria, La., from Psychiatric Clinic, Ann Arbor, Mich., to make examinations in his specialty, Lieut. George K. Pratt, Flint.

To Camp Shelby, Hattiesburg, Miss., from State Psychopathic Hospital, Ann Arbor, Mich., to make examinations in his specialty, Lieut. Ray S. Moorish, Flint.

To Fort Benjamin Harrison, for a course of instruction, Capts. Clarence M. Williams, Alpena; Edward C. Rumer, Flint; William W. Arscott, Rogers; Lieuts. Frederick S. Baird, Bay City; David D. Todd, Calumet; Edward W. Vis, Central Lake; Benjamin T. Goodfellow, Clio; George G. Rieckhoff, John H. Slevin, Detroit; Walter S. Sharpe, Dowagiac; Horace J. Beel, Grand Rapids; Glenn T. Soule, Henderson; Albert J. Schmaler, Hillman; James Rhines, Laurium; Isaiah Sicotte, Michigamme; Birge C. Swigt, Middleville; Albert R. Tucker, Mohawk; Theodore S. Crosby, Wakefield.

MINNESOTA

To Army Medical School, Washington, D. C., for instruction, Lieut. Henry V. Hanson, New London.

To Camp Mills, Garden City, L. I., for inspection and on completion of this duty to return to his proper station, Major Charles H. Mayo, Rochester.

To Cornell Medical [illegible] York, [illegible] of instruction military roentgenology, [illegible] J. [illegible]

To Fort Benjamin Harrison for instruction, Lieut. George H. Norris, Annadale.

To Fort Worth, Tex., from Fort Riley, for duty at the Signal Aviation School, Lieut. Arthur J. Lewis, Henning.

MISSISSIPPI

To Camp Wadsworth, Spartanburg, S. C., from Fort Benjamin Harrison, and report in person to the commanding general for duty, Lieut. Paul X. Browne, Jackson.

Par. 4126, Sept. 15, 1917, War D., as relates to Lieut. Paul Z. Browne, Jackson, is revoked.

MISSOURI

To Chicago, Ill., and St. Louis, Mo., for the purpose of establishing schools of plastic and oral surgery, section of surgery of the head and then to Rockford, Ill., to inspect division of plastic and oral surgery at base hospital, and on completion to return to his proper station, Major Vilray P. Blair, St. Louis, Mo.

To Fort Benjamin Harrison for instruction, Lieuts. Cameron A. Rose, Kansas City; Richard L. Russell, Humansville; Elsworth J. Smith, St. Louis.

To Phipps Clinic, Baltimore, Md., for a course of study in their specialty, Lieuts. William G. Patton, Farmington; Charles H. Burdick, St. Louis.

To Post Graduate Hospital, New York, from Army Medical School, Washington, D. C., for a course in orthopedics, and on completion of this course to proceed to Boston, Mass., for further instruction, Lieut. Lee H. Winemiller, Farley.

Letter, Sept. 20, 1917, No. 4448 War Dept., so much as relates to Lieut. Lee H. Winemiller, Farley, is revoked.

So much of Par. 6, Aug. 18, 1917, as relates to Lieut. Frank N. Wilson, St. Louis, modified as to read for service in the British Heaty Hospital.

NEBRASKA

To Fort Benjamin Harrison for instruction, Lieut. Louis E. Hanisch, Omaha.

To Fort Oglethorpe. for instruction, Lieut. Herman A. Gerbig, Friend.

Letter from War Dept., Sept. 12, 1917, No. 3887, for a course of instruction in military roentgenology in Kansas City, relating to Capt. William H. Mick, Omaha, is revoked.

To New York, N. Y., for instruction in military roentgenology, Capt. William H. Mick, Omaha.

NEW HAMPSHIRE

To Fort Benjamin Harrison for a course of instruction, Capt. Charles A. Sturtevant, Manchester.

To Fort Oglethorpe, from School of Military Roentgenology, Boston, Mass., for instruction, Lieut. Stilman G. Davis, Nashua.

To Fort Benjamin Harrison for instruction, Lieuts. Edmund W. Ill, Solomon J. Sambur, Newark.

To Fort Oglethorpe for instruction, Lieut. Charles L. Davis, South Dayton.

To Post Graduate Hospital, New York, N. Y., for a course of orthopedics, and on completion of this course to proceed to Boston, Mass., for further instruction, Lieut. Frank W. Pinneo, Newark.

Par. 2, War Dept., Sept. 10, 1917, which relates to Lieut. Edgar B. Funkhouser, Trenton, is revoked.

So much of Par. 72 and 73, War Dept. Aug. 27, 1917, as relates to Lieut. Abraham J. Gordon, Newark, is revoked.

NEW YORK

To Army Medical School, Washington, D. C., Lieuts. Wilfred V. Egan, Brooklyn; Fred G. Jones, Clark Mills; Arthur Krida, Schenectady.

To Camp Bowie, Fort Worth, Tex., from Neurological Institute, New York, to make examinations in his specialty, Lieut. John J. Hughes, Mt. Vernon.

To Camp Cody, Deming, N. M., from Psychopathic Hospital, Boston, Mass., to make examinations in his specialty, Lieut. Clarence J. O'Alton, New York.

To Camp Custer, Battle Creek, Mich., from Walter Reed General Hospital, for duty as tuberculosis specialist and assistant to the Army Medical Staff, Lieut. Nelson K. Gromm, Albany.

To Camp Lee, Petersburg, Va., from Walter Reed General Hospital, for duty as tuberculosis specialist and assistant to the Army Medical Staff, Capt. John P. Faber, Schenectady.

To Camp McClellan, Anniston, Ala., from Fort Benjamin Harrison to make examinations in his specialty, Lieut. Frederick C. Devendorf, Utica.

To Camp Mills, Garden City, L. I., from Army Medical School, Washington, D. C., for temporary duty in laboratory, Lieut. Fred. M. Meader, New York.

To Camp Meade, Annapolis Jct., Md., and report in person to the commanding general, 79th Division, for duty with the 23rd Engineers, Capts. Waldemar T. Browne, Brooklyn; for duty in connection with venereal diseases, Faxton R. Gardner, New York City.

To Camp Upton, Yaphank, L. I., for duty, Capt. Frederick P. Hammond, Lieut. Ammi B. Edgar, New York City.

To Camp Wheeler, Macon, Ga., from Buffalo State Hospital, Buffalo, N. Y., to make examinations in his specialty, Capt. Robert King, Buffalo.

To Fort Benjamin Harrison for instruction, Major Frank A. Walder, Lockport; Capts. Otto C. J. Von Renner, Buffalo; Walter H. Vosburg, Dunkirk; Raymond F. Longacre, Lee S. Shoninger, Archibald W. Taves, New York City; John D. Shipmam, Vernon; Lieuts. Summer E. Douglas, Adams; Bryan G. Shults, Albany; Arthur H. Wheeler, Albany; Joseph J. Dunnigan, Auburn; Edward Danforth, Bainbridge; Paul E. Betowski, Bath; George B. Reitz, Brooklyn; August M. Sartorius, Brooklyn; Irving S. Schweikraut, Brooklyn; Morris K. Silberman, Brooklyn; Alexander S. Sim, Brooklyn; Arthur E. McCarthy, Buffalo; Windsor R. Smith, Buffalo; Victor A. Tyrasinski, Buffalo; George H. Shaw, Camillus; Henry S. Edmunds, Cassadago; Walther C. A. Steffen, College Point; Hall G. Van Vlack, Forestville; Maxwell K. Willoughby, Genoa; Henry E. Clarke, Glens Falls; James H. Van Marter, Groton; William M. Sill, Jamestown; Patrick J. Hirst, Middle Grove; Charles A. Smith, New Rochelle; Henry C. Falk, Joseph Haas, Saul L. Meylackson, Isaac Reitzfeld, Charles P. Roach, Jay B. Rudolphy, Harry O. Saunders, William J. Scott, Isadore Seff, Solomon Shlimbaum, Henry B. Siglar, Benjamin J. Slater, Joseph T. Slonimsky, Louis J. Sokol, Oscar Spier, Maurice A. Sturm, Joseph Subkis, Lewis H. Taft, Edward H. Tonolla, Abraham Unger, Henry L. Wonner, Jr., New York City; Hamilton M. Southworth, Old Chatham; Bernard S. Strait, Penn Yan; Roy W. Bury, Philadelphia; Leo R. Tighe, Poughkeepsie; Roy J. Marshall, Le Clare Stuart, Rome; James A. Taggert, George B. Ubel, Salamanca; Stephen J. H. Reed, Sangerties; Leroy D. Sopee, Smyrna; William Trotter, Troy; John Peter Schneble, Wood Haven.

To Fort McPherson, Ga., from Camp Mills, and report to the commanding officer of that post for duty as chief of the medical service at the base hospital, Lieut. Charles N. B. Camac, New York City.

To Fort Oglethorpe for instruction, Lieuts. Johnston MacLeod, Flushing; Arthur G. Pilch, Rochester.

To Neurological School, Philadelphia, Pa., for four weeks' intensive training in brain surgery, Capt. Edwin Beer, New York City.

To Neurological Institute, New York, for a course in his specialty, Lieuts. Vincent W. Weiss, New York City; Samuel W. Hausman, Ogdensburg; Ward W. Millias, Rome.

To Psychopathic Hospital, Ann Arbor, Mich., from Fort Benjamin Harrison, for study in their specialty, Capt. George F. Mills, Oneida; Lieuts. Geoffrey C. H. Burns, Central Islip; Emil Altman, New York City.

To Post Graduate Hospital, New York, for a course of orthopedics and on completion of this course to proceed to Boston, Mass., for further instruction, Major Charles W. Hennington, Rochester; Lieut. William T. Shields, Troy.

To Signal Corps, Aviation School, Hazelhurst Field, from West Point, for duty, Lieut. F. L. Senger, Brooklyn.

To Washington, D. C., and report in person to the Surgeon General of the Army for duty in his office, Major William L. Hart, Madison Barracks; Lieut. Sanger Brown, White Plains.

To be relieved from the duty assigned him by Par. 154, War Dept., Aug. 22, 1917, and return to the inactive list of the M. R. C. of the Army, Major Edward S. Van Duyn, Syracuse.

Now on duty at Plattsburg Barracks, as contract surgeon be ordered to active duty as major, effective Sept. 3, 1917, Major M. S. Gregory, New York City.

To their Homes, Lieuts. Lemuel W. Gorham, Albany; Ambrose A. Scouler, Brooklyn; Abraham Skversky, New York City; John A. Conley, Penn Yan.

NORTH CAROLINA

To Army Medical School, Washington, D. C., for instruction, Lieut. Kelso A. Carroll, Raleigh.

To Camp Beauregard, Alexandria, La., from Camp Wadsworth, Spartanburg, S. C., for duty as Chief of the Surgical Service, Major John T. Burrus, High Point.

To Camp Des Moines, Ia., for instruction, Lieut. William H. Bryant, Henderson.

To Fort Benjamin Harrison for a course of instruction, Lieut. Wilbur G. Jenkins, Raleigh.

Letter, Aug. 31, 1917, No. 3194, War Dept., so much as relates to Lieut. Isaac M. Taylor, Morgantown, is revoked.

Honorably discharged on account of being physically disqualified, Lieut. Isaac M. Taylor, Morgantown.

NORTH DAKOTA

To Kansas City, Mo., for a course of military roentgenology, Lieut. Leslie G. Eastman, Hazen.

OHIO

To Army Medical School, Washington, D. C., for instruction, Lieuts. Maurice L. Allen, Albert L. Jones, Cleveland; Atlee R. Olmstead, Marshallville.

To Boston, Mass., for instruction in orthopedics, Lieuts. Charles M. Paul, Cincinnati; Barney J. Hein, Toledo.

To Camp Taylor, Louisville, Ky., from Cleveland, O., for duty as tuberculosis specialist and assistant to the Army Medical Staff, Capt. Milton J. Lichty, Cleveland.

To Camp Wheeler, Macon, Ga., from Walter Reed General Hospital, for duty as tuberculosis specialist and assistant to the Army Medical Staff, Capt. Samuel Hindman, Columbus.

To Fort Benjamin Harrison for instruction, Capt. Edward D. Sinks, Lima; Lieuts. Clyde K. Startzman, Bellefontaine; Melville D. Saash, Bluffton; Wiley T. Sprague, Chauncey; Walter H. Mytinger, Cincinnati; Samuel Zielonka, Cincinnati; Verner T. Scott, Clarksburg; Adlai E. Callaghan, Cleveland; Paul F. Davidson, Cleveland; Rudolph S. Reich, Cleveland; Ralph H. Sill, Cleveland; John M. Steel, Cleveland; John W. Tippie, Cleveland; James N. Wychgel, Cleveland; Nicholas L. Zinner, Cleveland; Clarence J. Schirack, Coldwater; Elgie R. Shaffer, Columbus; Otto N. Warner, Conneaut; Ivan L. Biggs, Custar; Warde B. Smith, Frankfort; Zalmon O. Sherwood, Geneva; Harry W. Shaw, Junction City; Donald De Costa Shira, Larue; William T. Stewart, Morning Sun; Jaffray J. Vega, National Military Home; Murray E. Reeder, Ohio City; Owen B. Van Epp, Port Clinton; Gale C. Guthrie, Uhrichsville; Edward McD. Cass, Utica; Harvey N. Trumbull, Woodville; David B. Phillips, Youngstown.

To Neurological Institute, New York, N. Y., for a course of study in his specialty, Lieut. John C. George, Dayton.

OKLAHOMA

To Camp Bowie, Ft. Worth, Tex., for duty, Lieut. Albert N. Earnest, Muskogee.

To Fort Worth, Tex., from Fort Riley, for duty, Lieut. Ross D. Long, Oklahoma.

OREGON

To Washington, D. C., and report to the Chief of Staff for temporary duty Army War College, and relieved from duty with the 42d Division, Camp Mills, L. I., Lieut. Spiro Sargentich, Portland.

PENNSYLVANIA

To Army Medical School, Washington, D. C., for instruction, Lieuts. Don C. Kyper, John R. T. Snyder, Altoona; Torrance J. Hanlon, Donora; Harry C. Fulton, Lancaster; Ralph E. Conn, Monessen; Harry F. Bailey, Monongahela; Humbert A. Granelli, David W. Kramer, Philadelphia; Galen D. Castleburg, Ralston; Valentine B. Eiler, Titusville.

To Boston, Mass., for instruction in orthopedic work and on completion of this course to proceed to New York (N. Y.) Post Graduate Hospital for further instruction, Lieuts. Ralph L. Rutledge, McKeesport; Robert E. Davison, James L. Gilmore, Pittsburgh.

To Camp Hancock, Augusta, Ga., from Phipps Psychopathic Clinic, Baltimore, Md., to make examinations in his specialty, Lieut. George P. Ard, Woodward.

To Camp Mills, Garden City, L. I., for duty with 42d Div., Major George S. Crampton, Philadelphia.

To Camp Shelby, Hattiesburg, Miss., from Fort Oglethorpe, for temporary duty to conduct cardiovascular examinations, Lieut. John H. Musser, Jr., Philadelphia.

To Fort Benjamin Harrison for a course of instruction, Lieuts. Eugen G. Reinartz, Solon L. Rhode, Charles A. White, Philadelphia; Howard L. Farquhar, Pittsburgh; Harry E. Garman, Spangler.

To Walter Reed Hospital, Tacoma Park, D. C., and report in person to commanding officer for special instruction in tuberculosis examinations, Lieut. William C. Spalding, Cresson.

To Washington, D. C., and report in person to the Surgeon-General of the Army for temporary duty in that office, Lieut. Floyd E. Keene, Philadelphia.

Par. 4223, Sept. 19, 1917, War Dept., as relates to Lieut. Alexander H. Colwell, Pittsburgh, is revoked.

To his home from Fort Niagara, N. Y., Lieut. David Riesman, Philadelphia.

PHILIPPINE ISLANDS

To Camp Pike, Little Rock, Ark., for duty with Ambulance Co. No. 44, Lieut. Seth L. Cox, Atimonan.

RHODE ISLAND

To Camp Upton, Yaphank, L. I., from Walter Reed General Hospital, for duty as tuberculosis specialist and assistant to the Army Medical Staff, Capt. James L. Wheaton, Pawtucket.

To Fort Benjamin Harrison for instruction, Lieut. Michael H. Scanlon, Westerly.

To Fort Oglethorpe, from school of Military Roentgenology, Boston, Mass., for instruction, Lieut. Jacob S. Kelley, Providence.

TENNESSEE

To Army Medical School, Washington, D. C., for instruction, Lieut. Clarence H. Glover, Memphis.

To Fort Benjamin Harrison for instruction, Lieut. Charles A. Robertson, Ridgetop.

To Fort Des Moines, Ia., for instruction, Lieut. Jonathan N. Rucker, Gallatine.

TEXAS

To Camp Kearny, Linda Vista, Calif., to make examinations in his specialty, Lieut. James W. Hill, Dallas.

To Fort Benjamin Harrison for instruction, Lieut. Wallace B. Guinn, Tivoli.

To Fort Des Moines, Ia., for instruction, Lieut. Allen A. McDonald, Calvert.

To Watertown, N. Y., from Army Medical School, to inspect ambulance bodies, Major Harold W. Jones, San Antonio.

VERMONT

To Camp Meade, Annapolis Jct., Md., from Fort Sheridan, Ill., for duty, Lieut. Horatio N. Jackson, Burlington.

VIRGINIA

To Army Medical School, Washington, D. C., for instruction, Lieut. Rockwell E. Smith, Crozet.

To Camp Green, Charlotte, N. C., from Neurological Institute, New York, N. Y., to make examinations in his specialty, Lieut. Paul V. Anderson, Richmond.

To Fort Benjamin Harrison for instruction, Lieuts. George B. Harrison, Colonial Beach; Robert J. Styers, Jetersville; John H. Hare, Newland; Ira Hurst, Parksley; Granville Eastham, Rapidan; Robert E. Timberlake, Junius E. Warinner, Richmond; Ernest H. Muse, Roanoke.

To Rockefeller Institute for Medical Research, New York, N. Y., for a course of instruction in laboratory work, Capt. Erasmus G. Hopkins, Richmond.

WASHINGTON

To Los Angeles, Calif., for a course of instruction in military roentgenology, Lieut. Roy C. Baumgarten, Seattle.

To Mineola, Long Island, for the purpose of making inspection of the aviation camp, Col. George H. Crabtree, Fort Lawton.

WEST VIRGINIA

To Fort Benjamin Harrison for instruction, Lieuts. George W. Shriver, Clendenin; James O. Hicks, Huntington; Charles G. Willis, Kingston; Frank C. Shafer, Roanoke; Harry R. Parker, Williamson.

WISCONSIN

To Boston State Hospital, Boston, Mass., from Fort Riley, for a course of study in his specialty, Lieut. Charles C. Rowley, Winnebago.

To Camp Meade, Annapolis Jct., Md., from Fort Sheridan, Ill., for duty, Lieut. Ralph Kayeen, Oconomowoc.

To Phipps Clinic, Baltimore, Md., for a course of study in his specialty, Lieut. William J. Fleming, Wauwatosa.

Medical News

(PHYSICIANS WILL CONFER A FAVOR BY SENDING FOR THIS DEPARTMENT ITEMS OF NEWS OF MORE OR LESS GENERAL INTEREST: SUCH AS RELATE TO SOCIETY ACTIVITIES, NEW HOSPITALS, EDUCATION, PUBLIC HEALTH, ETC.)

ILLINOIS

Rosenow in Rock Island.—At a special meeting of the Rock Island County Medical Society, held in Rock Island, September 27, the essayist of the evening was Dr. Edward C. Rosenow, Rochester, Minn., who spoke on "Infantile Paralysis."

Personal.—Drs. William E. Buehler and Andrew M. Harvey, Chicago, have been elected directors of the public safety commission in Cook County.——Dr. Clara E. Hayes of the Peoria State Hospital has been appointed superintendent of the State Training School for Girls, Geneva.

Work for the Insane.—On account of the shortage of knit underwear and stockings due to the war, the state welfare commission has determined on installing the machinery at the Elgin State Hospital for making needed articles of clothing, as well as brooms, brushes, furniture and shoes.

Sanitary Assignments.—Dr. C. St. Clair Drake, Springfield, director of the public health of the state, has announced the following assignments: Dr. Clarence W. East, Evanston, detached from Camp Grant, Rockford, to investigate poliomyelitis in Cook County; Dr. Arthur Pearman, medical health officer for Camp Grant health district; Dr. Alexander F. Stewart, Oneida, health officer for the Western District; John A. Kappelman, Evanston, relieved as medical officer of the Fort Sheridan District, excepting special assignments, and detailed to the Northwest Health District, with headquarters in Chicago; Major John A. Robison, M. R. C., U. S. Army, medical officer for the Fort Sheridan health district, and Dr. Charles E. Crawford, assigned to supervision of the Northwestern health district, Rockford.

Chicago

Personal.—Dr. Clarence W. Leigh has been appointed city physician, succeeding Dr. Michael J. Purcell.——Dr. James M. Neff, who was on duty with the Murphy Unit in Europe for several months, has returned and resumed practice.

One Million Dollars for Hospital.—At the November election, the people of Cook County will be asked to approve a bond issue of $1,000,000 for the erection of two hospitals as branches to Cook County Hospital. The first, to accommodate 200 patients, is asked for South Chicago, and the second, in the stock yards district, is intended as an emergency hospital.

Poliomyelitis.—September 28, there were said to be 155 cases of infantile paralysis in Chicago and between forty and fifty cases in Cook County outside of the city. Eleven new cases, with four deaths, were reported in Chicago for the date mentioned. According to a statement of the health commissioner, 50 per cent. of the cases in the present epidemic had proved fatal. Seventeen meetings were held in as many schoolbuildings of the city on the date mentioned at which physicians gave talks to more than 12,000 citizens on the disease and measures for its prevention.

Military Assignments.—Major Harry D. Orr, M. C., assigned to the One Hundred and Twenty-Second Infantry, has been appointed director of Illinois field ambulance companies. Capt. Robert J. Gay has succeeded Major Orr as regimental surgeon.——Major William J. Swift, M. C., has been appointed director of Illinois field hospital companies at Camp Logan, Houston, Texas.——Dr. Cassius C. Rogers has been commissioned major, and Dr. J. Lloyd Hammond, lieutenant, in the Medical Corps, Illinois National Guard, and assigned to the First Reserve Infantry.——Dr. Maurice L. Blatt has been commissioned major, and Dr. Arthur H. Parmelle, lieutenant, in the Medical Corps, and assigned to duty with the Second Illinois Reserve Infantry.

INDIANA

Personal.—Dr. William Shiner, superintendent of the Pathological Laboratory of the Indiana State Board of Health, has been offered the professorship of pathology in the University of Texas.——Dr. Daniel F. Randolph, Waldron, has entered St. Vincent's Hospital, Indianapolis, on account of injuries received in the overturning of his automobile recently.

State Society Meeting.—The Indiana State Medical Society met in Evansville, September 26, 27 and 28, and elected the following officers: Dr. Joseph R. Eastman, Indianapolis, president; Drs. Victor V. Cameron, Marion; Harvey H. Martin, Laporte, and Eugene A. Sturm, Jasper, vice presidents, and Dr. Charles N. Combs, Terre Haute, was reelected secretary-treasurer. It was voted unanimously to hold the 1918 meeting in Indianapolis.

IOWA

Poliomyelitis.—What appeared to be a new outbreak of poliomyelitis in Davenport occurred, September 25, when three new cases were reported in the preceding twelve hours. In an effort to check the epidemic in Davenport the health authorities made a regulation, September 20, that no mail would be allowed to go out from homes quarantined on account of the disease, and the postal authorities acquiesced in the rule and returned mail from such houses.

MARYLAND

Typhoid Fever Epidemic.—An epidemic of typhoid fever has broken out at Arlington, Baltimore County. To date there are fourteen cases of the disease, among them five in one family and six in another. Dr. Henry A. Naylor, Pikesville, who is health officer of the district, reported the cases to the state board of health.

Personal.—Dr. Thomas B. Futcher, Johns Hopkins Hospital, will sail shortly for England, where he will be in charge of the Canadian Military Hospital at Orpington, Kent. Although Dr. Futcher has been living in Baltimore for many years, he is a British subject, being a Canadian by birth. He has been commissioned a lieutenant-colonel in the Canadian Expeditionary Force.

MONTANA

Hospital Addition Completed.—A twenty-room addition has been made to the Park Hospital, Livingston, at a cost of $20,000. The hospital now has a bed capacity of fifty.

Personal.—Dr. William C. Riddell, Helena, has been commissioned major, M. C., Mont. N. G., and assigned to the Second Infantry.——Dr. Michael J. Casserly, Hamilton, who is on duty with the Canadian Army Medical Corps in France, has been wounded.——Dr. James H. Irwin, Great Falls, has been commissioned major, and ordered to duty at American Lake, Washington.

Epidemic Diseases.—Since January, only twenty-four cases of infantile paralysis have been reported to the state health authorities. This compares favorably with 1916, when 108 cases were reported during the same period. During September, twelve cases of smallpox were reported in Livingston.——In Butte, fifteen cases of smallpox were reported during the first half of September.

NEW YORK

Personal.—Dr. Charles G. Wagner, superintendent of the Binghamton State Hospital, is reported to be seriously ill at his home.——Dr. Moses Rosenberg, Rochester, surgeon on the British steamer *Verdi*, which was reported to have been sunk by a German submarine, was saved.

New Officers.—At the annual meeting of the Eighth District Branch of the Medical Society of the State of New York, held at Buffalo, September 13, the following officers were elected: president, Dr. Albert T. Lytle, Buffalo; vice presidents, Drs. Edward Torrey, Olean, and William R. Thomson, Warsaw; secretary, Dr. Lyman C. Lewis, Belmont, and treasurer, Dr. Fitch H. Van Orsdale, Belmont.

Quarantine at Camp Mills.—The Forty-Second Division of the National Guard Army encamped near Mineola, L. I., is threatened with an outbreak of cerebrospinal meningitis. Dr. Fred M. Meader of the Surgeon-General's Office, who has been sent to the camp to handle the situation, has established three quarantines. Cultures taken in the One Hundred and Sixty-Seventh Infantry have shown a number of meningitis carriers. These have been isolated, and no further spread of the malady is anticipated. There was one death in the regiment which lead to the investigation.

New Vital Economics Department at Rochester.—The University of Rochester is organizing a department, to be known as the Department of Vital Economics, as an extension of the Department of Household Economics of the Mechanic's Institute. The course will be arranged with a view to preparing young men and women for more rational physical living and to the training of students for positions in public health offices. Dr. John R. Murlin, who for the past eight years has been professor of physiology in the Medical School of Cornell University, has been appointed director. This department, the first of its kind in this country, has been made possible by a bequest of $800,000 made available by the will of Lewis P. Ross, the income of which may be used "to the end that human life may be prolonged with increased health and happiness."

Civil Service Examinations.—The civil service commission announces that examinations will be held, November 3, to fill the following positions:

Assistant bacteriologist, state department of health; open to men and women; salary $1,200 to $1,800; ages 21 to 35 years; candidates must have a thorough knowledge of the principles of bacteriology, and considerable practical experience in that work, including preparation of purified antitoxins.

Assistant physician, regular or homeopathic, to provide eligibles for positions as assistant physician in the state hospitals and other positions of a similar nature; salary $1,200 to $1,600, with maintenance; open to men and women, licensed medical practitioners of New York; graduates from a registered medical school, and with at least one year's experience on the resident medical staff of a hospital, or medical intern or clinical assistant in a state hospital, or three years' consecutive practice of medicine.

Applications should be made to the State Civil Service Commission, Albany, prior to October 22.

New York City

New York Academy of Medicine.—The meetings of the New York Academy of Medicine for the season 1917-1918 began on the evening of October 4 with an address by Dr. Alexis Carrel on "Principles of the Treatment of Wounds."

Mental Examination of Troops.—The work of making a mental examination of the men in the Twenty-Seventh Division has been begun by Lieut. Samuel Leopold, formerly of the University of Pennsylvania, who has just completed work of this kind in the Pennsylvania National Guard.

Institution for Feebleminded Children.—The cornerstone of the first of a group of eleven buildings, to be known as the Institution for Feebleminded Children, which the Department of Charities is erecting on Randall's Island, was recently laid with appropriate ceremonies. The principal speakers were Mayor Mitchell and Commissioner of Charities John A. Kingsbury.

Draft Board Doctor on Trial.—The trial of Dr. Henry Seligman, a volunteer examining physician for District Board 52, charged with accepting a bribe to release a conscript from military service, was recently reached. The testimony produced by the regular physicians on the board show that the defendant had examined and found unfit for service a man who, on reexamination, easily passed all physical tests.

Columbia University Opens.—The respective institutions of Columbia University opened their doors for the year 1917-1918 by the usual addresses. Among the most notable of these was that of Prof. Hans Zinsser, who made the opening address for the medical school. His theme was "Opportunities for National Service," and his summary is characterized as a suitable profession of faith for loyal Germans in this country.

Springs Cause Typhoid Fever in New York.—The search for the source of a small outbreak of typhoid fever in the Bronx has led to the discovery that the infection was probably transmitted by the drinking of water from an infected spring fed by drainage from fertilized fields in the vicinity. Laboratory tests of the water of several other springs in that section of the city indicate that it is unsafe for drinking. The department of health has placarded a number of these springs as unfit for drinking purposes, and has issued a warning against drinking the water from springs within the city limits.

OHIO

Schools Ordered Closed.—The public and parochial schools of East Liverpool, which opened September 10, were ordered closed for one week on the discovery of two cases of anterior poliomyelitis.

Poliomyelitis.—Opening of the Mansfield schools was postponed until September 17 on account of the fear of the spread of poliomyelitis.——At Wooster a similar postponement was had. September 6, only two patients remained under treatment.——In Cleveland eighteen cases have been treated since June 1, none of them proving fatal.

Academy Meeting.—At the meeting of the Cleveland Academy of Medicine, September 28, Lieut.-Col. Ethelbert B.

Hardy, D. S. O., in command of the Military Base Hospital, Toronto, narrated "Experiences of Medical Officers at the Front," and Lieuts. Benjamin R. McClellan, Xenia, and Murray B. McGonigle, Toledo, spoke on "The Medical Department of the Army."

Schoolteachers Subnormal Physically.—At Cincinnati, twenty-four of the forty-two schoolteachers who took the physical examination for positions in the public schools were found to be underweight. None was rejected; one was conditioned on account of defective vision and six others were advised to consult oculists; two were found to have impaired hearing, and one, diseased tonsils.

Sanatorium Capacity Doubled.—The capacity of the Warrensville Tuberculosis Sanatorium has been doubled since January 1 of last year. The present capacity of the institution is 390. The Children's Colony can admit forty-five more patients than before, and by the remodeling of two old structures accommodation has been provided for sixty additional adults. Three more cottages, with the capacity of twenty each, will be completed within a few weeks.

Personal.—Dr. Charles F. Hoover, Cleveland, assistant director of Lakeside Base Hospital No. 4, has returned on leave of absence.——Dr. O. van der Stricht, Ghent, Belgium, for the last two years fellow in Cytology in the Anatomical Laboratory of Western Reserve University, Cleveland, has been appointed lecturer in anatomy in the Johns Hopkins University, Baltimore.——Dr. Carell S. Mundy, superintendent of the Toledo Contagious Disease Hospital, has resigned to enter the Army medical service.——Dr. Clarence D. Selby, Toledo, has resigned as commissioner of public health, and Dr. Charles Dreyer, city physician, has been appointed his successor.——Dr. Burt A. Marquand, Dover, suffered fracture of several ribs in a collision between his automobile and an interurban car.——Dr. Sterling H. Ashum has been appointed city physician of Dayton, succeeding Dr. Daniel G. Reilly, deceased.——Dr. William K. Ruble, Martinsville, has been elected treasurer of Clinton County. ——Dr. Ralph A. Bunn, Dayton, has been appointed assistant chief surgeon at the Dayton Soldiers' Home.——Dr. Roy E. Bushong, Athens, has been appointed acting superintendent of Athens State Hospital during the absence, on leave, of Dr. Ora O. Fordyce.

PENNSYLVANIA

Dysentery Epidemic.—An epidemic of dysentery is reported in the townships on the west side of the Susquehanna River. In Larksville and Plymouth there are reports of 295 persons ill with the disease, with, thus far, fifteen deaths.

Personal.—Dr. Arthur A. Woods, Erie, has moved to California.——Dr. Henry L. Orth announces his approaching retirement, after twenty-seven years' service, as superintendent of the Pennsylvania State Lunatic Hospital.

New Officers.—At the annual meeting of the Seventeenth Censorial District Medical Association, held in Sunbury, September 6, Dr. John W. Bruner, Bloomsburg, was elected president of the Pennsylvania State Lunatic Hospital, Harrisburg.

Branch County Society Organized.—The physicians from the northern portion of Washington County met in Burgettstown, September 14, and organized the Northern Branch of the Washington County Medical Society, and elected Dr. Audley O. Hindman, president.

Officers Elected.—At the recent meeting of the Pennsylvania State Medical Society, the following officers were elected: president, Dr. Frederick L. Van Sickle, Olyphant; vice presidents, Drs. Walter F. Donaldson, Pittsburgh; Benjamin F. Royer, Harrisburg; David N. Dennis, Erie, and Walter J. Leaman, Lancaster; secretary, Dr. Cyrus L. Stevens, Athens; assistant secretary, Dr. Christian B. Longenecker, Philadelphia; treasurer, George W. Wagoner, Johnstown; trustees, Ira G. Shoemaker, Reading; Frank G. Hartman, Lancaster; Harry W. Albertson, Scranton; Spencer M. Free, Dubois; Donald Guthrie, Sayre, and Jay B. F. Wyant, Kittanning.

Philadelphia

Personal.—Lieut. Howard F. Keating, on duty on the western front, was slightly wounded during the air raid of September 24.

University of Pennsylvania Opening Exercises.—The University of Pennsylvania opened its 177th college year in Weightman Hall, September 28, with a student body much depleted by enlistments for the war. About 60 per cent. of the old students were missing, although the freshman class is larger than ever. The medical department has an exceptionally large entering class. In spite of the large number from the department who enlisted, the total enrolment of medical students is increased. A number of changes have been made. In the medical school, Drs. Joseph McFarland, Horatio C. Wood, Jr., John C. Heisler and Seneca Egbert have been added to the faculty. Dr. Allen J. Smith takes the place of Dr. William Pepper as dean.

UTAH

Smallpox.—During the week ending September 15, ten cases of smallpox were reported in Salt Lake City.——Lark is under strict quarantine on account of smallpox.

Called to California.—Dr. Daniel H. Calder, for many years superintendent of the State Mental Hospital, Provo, has been appointed a member of the faculty of the Medical College of the University of Southern California, Los Angeles, and a member of the staff of the Los Angeles County Hospital.

State Association Meeting.—The twenty-third annual meeting of the Utah State Medical Association was held at the Hotel Utah, Salt Lake City, September 12-14, under the presidency of Dr. Samuel C. Baldwin, Salt Lake City. Salt Lake City was selected as the place of meeting for 1918, and the following officers were elected: president, Dr. Frederick Stauffer, Salt Lake City; vice presidents, Drs. Andy J. Stewart, Provo; Edward I. Rich, Ogden, and Ernest Van Cott, Salt Lake City; secretary, Dr. W. Brown Ewing, Salt Lake City (reelected); treasurer, Dr. Francis A. Goeltz, Salt Lake City; councillor, Eugene H. Smith, Ogden; delegate to the American Medical Association, Dr. Thomas J. Howells, Salt Lake City, and alternate, Dr. Joseph R. Morrell, Ogden. Among the features of the meeting were the illustrated lecture by Dr. Richard C. Corwin, Pueblo, Colo., on "War Surgery in France and America," in which he detailed the Carel-Dakin treatment of wounds, and the address of Dr. Palmer Findley, Omaha, on "Obstetrics as a Lost Art."

WISCONSIN

Typhoid Fever at Marshfield.—During the week ending September 15, twenty-six cases of typhoid fever were reported to the health officers of Marshfield.

Tuberculosis Board Appointed.—The Surgeon-General has appointed a tuberculosis commission which is making a survey of the troops at Camp Robinson, near Sparta. The personnel of the commission is as follows: Drs. Arthur J. Patek, Lawrence G. Sykes, J. Gurney Taylor, James D. Madison and William B. Ford.

Sanatorium Items.—The issue of bonds for $40,000 for the addition to Blue Mound Sanitarium has been approved by Judge C. B. Woods.——Work has been commenced on the infirmary building of the Madison Anti-Tuberculosis Association. The general contract has been let for $6,775. The infirmary will be a frame structure, two stories in height, and 36 by 60 feet.

Personal.—Dr. Frank H. Turner, Frederic, is reported to be ill with pneumonia.——Drs. Raymond G. Arveson and John Diamond have leased the Frederic Hospital to the Sisters of St. Joseph, Superior.——Health Commissioner George C. Ruhland, Milwaukee, has resigned, and has been called to duty at Fort Sill. The employees of the department presented Dr. Ruhland with an alligator writing case and a gold wrist watch.

Changes of Name of Public Institutions.—The following changes in the names of public institutions in Milwaukee County were recently announced: Milwaukee County Alms House to Milwaukee County Infirmary; Milwaukee County Home for Dependent Children to Milwaukee County Home for Children; Milwaukee County Hospital for Acute Insane to Milwaukee County Hospital for Mental Diseases; Milwaukee County Asylum for Chronic Insane to Milwaukee County Asylum for Mental Diseases.

Acts Passed by Last Legislature.—The legislature, during its last session, passed the following bills to strengthen the facilities of the state in its fight against tuberculosis: An act appropriating $15,700 for the erection of a cottage, workshop and electric plant at Tomahawk Lake Camp, and $15,000 for a refectory and employees' building at the camp; an act appropriating $75,000 for the erection of a new state sanatorium in northern Wisconsin, and an act increasing the state aid for patients in county tuberculosis sanatoriums from $125,000 to $141,000 for the first year of the biennium, and $165,000 for the second year.

Vigilance Committee Advised.—The Wisconsin Antituberculosis Association urges the appointment of a citizens' tuberculosis vigilance committee in every community, the duties of which shall be to request examining boards to obtain records of all active and suspected cases of tuberculosis, to secure the volunteer services of physicians to whom the board examiner may refer all suspected and borderline cases for more thorough examination; to secure proper care and instruction of the patient by the follow-up system, and to assist, where necessary, in securing additional sanatorium facilities for the care of these cases and of others, with special reference to returned soldiers.

Hospital Notes.—The directors of the Plymouth Hospital announce the opening of that institution, October 1. The hospital will accommodate thirty-five patients.——The new Riverview Hospital, Grand Rapids, erected at the cost of $25,000, was opened for public inspection, September 4. The building is two stories and basement in height, 75 by 81 feet, and is thoroughly equipped.——The Winnebago County Medical Society and the Oshkosh Medical Club have endorsed the plan of Lakeside Methodist Hospital Company, to take over and operate Lakeside Hospital.——Dr. Sylvester G. Pake, formerly of Superior, has moved to Hayward, where he has leased the parochial school building, which is being remodeled for a hospital.

GENERAL

National Board Examination.—The National Board of Medical Examiners will hold its next examination in Chicago, October 10 to 18, inclusive. About sixty-five physicians have applied. Others who desire to take the examination should apply at once to the secretary, Dr. John S. Rodman, 2106 Walnut Street, *Philadelphia*.

Bequests and Donations.—The following bequests and *donations* have recently been announced:

Faculty of Medicine, McGill University, Montreal $500,000; Montreal General Hospital, $500,000; Montreal Maternity Hospital, $100,000, and Royal Institute for the Advancement of *Learning (McGill), for* MacDonald College, $1,000,000, by the will of Sir William MacDonald, Montreal, Chancellor of McGill University.

Mount Sinai Hospital, New York, $100,000, to be used for *the purpose of* Cancer Research Work, by the will of Julian A. Hillman.

Tri-State Physicians Elect Officers.—At the annual meeting of the Tri-State District Medical Society, held in Dubuque, September 5, the following officers were elected: president, Dr. William B. Peck, Freeport (reelected); honorary president, Dr. James R. Guthrie, Dubuque; vice presidents, Drs. Clarence A. McGuire, Dubuque; Edwin S. Gillespie, Wenona, Ill., and Lawrence H. Prince, Madison, Wis., and secretary-treasurer, Dr. Nelson C. Phillips, Freeport, Ill. (reelected).

New Officers for Missouri Valley Society.—At the thirtieth annual meeting of the Medical Society of the Missouri Valley, held in Lincoln, Neb., September 20 and 21, the following officers were elected: president, Dr. Artemas J. MacKinnon, Lincoln, Neb.; vice presidents, Drs. Thomas M. Paul, St. Joseph, Mo., and Paul E. Gardner, West Hampton, Iowa; secretary, Dr. Charles Wood Fassett, Kansas City, Mo. (reelected for the sixteenth term), and treasurer, Dr. Oliver C. Gebhart, St. Joseph, Mo. Omaha was selected as the next place of meeting.

Negro Professional Men Elect Officers.—At the annual meeting of the National Medical Association, composed of colored physicians, dentists and pharmacists, held in Philadelphia, August 29 and 30, the following officers were elected: president, Dr. George A. Cabaniss, Washington, D. C.; president elect, Dr. D. A. Ferguson, D. D. S., Richmond, Va.; vice presidents, Drs. Henry M. Green, Knoxville, and John P. Turner, Philadelphia; chief secretary, Dr. Walter G. Alexander, Orange, N. J., and assistant secretary, A. L. Jackson, Phar.D., Philadelphia.

Tuberculosis Conferences.—Conferences on antituberculosis, under the auspices of the National Association for the Study and Prevention of Tuberculosis, will be held in October and November, as follows:

North Atlantic Tuberculosis Conference at Baltimore, October 17 and 18.

New England Conference in Rutland, Vt., October 4 and 5.

Mississippi Valley Conference in Minneapolis and St. Paul, October 8, 9 and 10.

Northwestern Conference in Portland, Ore., October 15 and 16.

Southwestern Conference in Grand Canyon, Ariz., October 22 and 23.

Southern Conference in Chattanooga, Tenn., November 9 and 10.

The war problems of tuberculosis will be the dominant subject of discussion at all these conferences.

FOREIGN

International Child Welfare Congress.—The second International Child-Welfare Congress will be held in Montevideo in 1918. The first congress was held in Buenos Aires in July, 1916. The president of Uruguay, through the *Diario Oficial* of Aug. 10, 1917, issued a decree providing for the holding of the congress, March 17 to 24, 1918, under the auspices and protection of the government. A monthly sum of 100 pesos gold will be paid by the Uruguayan government to the executive committee appointed by the first congress. Invitations will be sent to all other American countries to participate by sending delegates to the congress.

Society for Research on Medical Biology.—The Swiss Société helvétique des Sciences naturelles was the original model on which Virchow founded the German organization which meets once a year for what are popularly called the *Naturforscher* congresses. The venerable Swiss association now announces the formation of a section or subsociety devoted to medical biology, to be known as the Société de Médecine et de Biologie. Professor Hedinger of the University of Basel is the moving spirit in the matter. The inaugural meeting is to be held this month at Zurich. It is hoped for a large membership among physicians interested in medical biologic questions.

CANADA

Personal.—Capt. Roland W. Young, Oshawa, Ont., recently returned from two years' service with the R. A. M. C. in Malta and Egypt, has been appointed on the staff of the Whitby Military Hospital, Whitby, Ont.——Sir James A. Grant, M.D., Ottawa, Ont., was recently tendered a reception at Detroit by a number of prominent citizens.

Medical Writers Censored.—Articles on medical and surgical subjects connected with the war having been appearing from time to time in various Canadian and other medical periodicals, attention has been called to this by special orders issued by the British Expeditionary Forces, of which the Canadian Expeditionary Forces form a part, and hereafter physicians and surgeons are forbidden to contribute such articles without securing the consent in advance of publication of the Director-General of Medical Services, to whom all articles on such subjects must be submitted.

***Canadian* Public Health Association Meeting.**—The annual meeting of the Canadian Public Health Association was held in Ottawa, September 27 and 28. Dr. Joseph D. Page, Quebec, in his presidential address, dealt principally with the immigration problems of Canada as compared with those of the United States, considering that the holding of steamship companies, by the latter, responsible for the class of immigrants brought to the country, was much in advance of Canadian methods. In advocating a ministry of public health, he thought Canada would not get that until there was a strong public sentiment behind it. There was need for getting ready now in preparation for coming immigrants after the war. Capt. Gordon A. Bates, Toronto, C. A. M. C., read a paper on venereal diseases, contrasting the efficiency with which those diseases were dealt with in the army, and the comparative indifference of the civic authorities. He gave statistics of 417 cases recently analyzed, which showed seventy infected men under 20 years of age and 144 between 21 and 25 years. About 260 were single men and thirty-six were married, the balance being (likely) widowers. In 295 cases the influence of alcohol was denied. Forty-four were classed as professionals, while in 127 cases no money was paid. Sixty cases of infection took place in the boarding houses of the females; 119 cases out of doors in parks, etc. Dr. Bates considered that immediate steps should be taken to facilitate early diagnosis and prompt treatment. Venereal diseases should be made quarantinable immediately, and a law passed in Canada to that effect. Major Maxwell Lauterman, Montreal, stoutly advocated a Minister of Public Health for Canada, as venereal diseases were the greatest menace of the civilized world today, bar none. Mr. Miles M. Dawson, an actuary of New York, and Mr. I. M. Rubinow, New York, dealt with the question of health insurance. They strongly advocated noncommercial insurance. Dr. Charles J. C. O. Hastings, M. O. O. H., Toronto, took up the question of "patent medicines" and alcoholic mixtures. He said there are too many "cures" on the market containing an excess of drugs and alcohol, the latter particularly since prohibition had gone into effect. The consumption and cancer "cures" are robbing the victims of those diseases of the only chance they had of being cured. Manufacturers of such concoctions are criminals of the worst type and highest degree. There is no worse menace to the public than the makers of such alleged cures. Dr. Hastings advocated health insurance on the same plan as in England, and he believed the government would soon have to take action. Dr. Alan G. Brown, Toronto, deplored the fact that Canadian mothers do not do their duty in respect to maternal nursing. He quoted statistics to prove that American women and even foreign women were 50 per cent. ahead of the women of Canada in this respect. Canada, he averred, stands alone for total inactivity on the part of the state in regard to child welfare.

PARIS LETTER

PARIS, Sept. 2, 1917.

The War

PENETRATING WOUNDS OF THE KNEE-JOINT

Dr. Mauclaire, agrégé professor and hospital surgeon at the Faculté de médecine at Paris, has submitted a report to the Société de chirurgie of Paris on a communication sent to the society by Dr. Stern in October, 1916, which dealt with articular wounds of the knee treated before Loubat and Moiraud had extolled the merits, in such cases, of immediate mechanical disinfection followed by primary suturing, a method which Stern has likewise since applied with satisfaction.

From the study of seventy-one cases taken from his former practice, Stern draws the following conclusions as regards indications for operation:

He has encountered several cases of simple intra-articular setons, caused by a rifle bullet, with punctiform orifices at the point of entrance and exit, and without bony lesions. Compression and immobilization sufficed to cure these patients, if carefully attended to, and extensive articular movement was preserved. It goes without saying, furthermore, that, if there is an intra-articular projectile, and there is the slightest sign of articular reaction, it is necessary to intervene in these wounds with punctiform seton. Exploratory arthrotomy is indicated immediately after the wound is received, in order to remove the isolated splinters, or to extract an intra-articular projectile, the presence of which roentgenography has revealed. The U-shaped subpatellar incision should be performed, unless the lesions are diffuse. The parapatellar incision is often sufficient and is not so destructive of tissue as the subpatellar. Arthrotomy and evacuation are indicated at the onset of infectious arthritis with extravasation, and this may suffice, provided immediately afterward the symptoms of articular septicemia are seen to disappear. Typical primary articular resection should be resorted to if there are extensive bony lesions. Secondary resection will be done if the suppurative arthritis becomes complicated by grave septicemic symptoms. Stern favors general anesthesia by means of ethyl chlorid, since it causes only a slight shock to the patient. He strongly disinfects the articulation with ether. He makes as few changes of dressings as possible. He uses a plaster apparatus which consists of two distinct segments (one including the thigh and one including the lower leg), joined together by encircling bands and fitting one within the other, which makes it possible, after the twelfth day, to commence to draw the bony surfaces together, after the manner recommended by Chaput and Alquier. The posture of the foot should be carefully watched, as there is a tendency toward talipes equinus. Amputation of the thigh is, of course, imperative when the infection is very threatening or when the bony lesions are multiple and extensive.

In combating septicemic symptoms Stern uses injections of a 47 per cent. glucose solution, injections of colloidal gold, theobromin (which promotes diuresis), laxatives and perspiration induced by a system of electric bulbs placed under the bedcovers.

The immediate results were eight deaths out of seventy-one cases, or 11.2 per cent. (five deaths, or 15 per cent., out of thirty-three infected cases; three deaths, or 8 per cent., out of thirty-eight noninfected cases). Complete arthrotomies caused four deaths out of thirty-four cases (12 per cent.). Seven unilateral arthrotomies, four total rotulectomies, three partial rotulectomies, and seven typical total resections of the knee-joint did not occasion a single death. Three partial resections (condyle) caused one death. Ten amputations of the thigh resulted in three deaths (30 per cent.), and three cases in which the surgeon refrained from operating resulted in recovery.

The more remote results may be thus described: Of the twenty-seven arthrotomies that could be followed up to the time of their cicatrization and beyond, there were seven cases of total ankylosis, nine cases of partial ankylosis, eight cases in which the flexure equaled or exceeded 90 per cent. of the normal, and three cases of perfectly normal flexure. It is only proper to state, however, that a number of the patients who came under the second and third categories could be still benefited by mechanotherapy, and this treatment continued to be applied. Of the seven partial or total rotulectomies, cicatrization took place in three cases, in one of which almost complete mobility was secured, and in the other two cases there was almost complete ankylosis. Of the seven cases of typical resection of the knee-joint, it was possible to learn the later history in four instances. The age of the patients varied from 19 to 30 years. Of these four cases there were two cases of complete consolidation after three and a half months, one case of incomplete consolidation after 145 days, and one case of incomplete consolidation after ninety days.

A CENTER FOR VOCATIONAL REEDUCATION ESTABLISHED

Under the auspices of Fernand David, minister of agriculture, Justin Godart, undersecretary of state for the military medical service, and Medical Inspector Polin, director of the medical service of the military government of Paris, a center of vocational reeducation for the war wounded (both the wounded under treatment and the wounded who have been discharged from active service) has been created at the national school of agriculture at Grignon, in Seine-et-Oise.

The instruction at Grignon will comprise practical courses looking toward the reeducation of mind, nerve and muscle, such as courses in gardening, agricultural work, and all the trades that serve the needs of the agriculturist: saddle making, harness making, basket work, carpentry, iron and metal work, horseshoeing, masonry, cooperage, etc. The new institution can accommodate 500 students. For those who are discharged from active service but who cannot continue their antebellum vocation, courses of general instruction, in accountancy, stenography, typewriting, mechanical drawing, prosthetic dentistry, tailoring, hairdressing, domestic science and the manufacture of playthings, all of which are presided over by experts, have been established.

Potatoes in Relation to Bread Production

M. Maurice Viollette, food administrator, sent out recently a circular letter of inquiry addressed to the prefects of the various departments, asking them to express an opinion on the result of the experiments to be conducted with regard to the mixture of potatoes and flour in the preparation of bread. He received a large number of replies testifying to the fact that the experiments gave complete satisfaction. The report that the prefect of the department of Eure-et-Loir received on this subject from M. Carola, director of the agronomic station at Chartres, states that bread made with the addition of boiled potatoes in the proportion of 20 per cent. has been found equally as good, if not better, than the bread now in use. It has also been observed that it keeps fresh longer. A round loaf cut ten days after it was baked was still fit for consumption. On analysis this bread has been found to present the following composition:

Water	34.70
Ash	1.18
Nitrogenous material	6.90
Starch	56.50
Cellulose	0.72
Total	100.

This bread is capable of furnishing the human system with 253.6 calories per hundred grams of the material; that is to say, a figure equal to that of the bread now in use (white, rye and barley). In case of need, the potato would, then, constitute no mean resource in view of its power to improve the quality of bread. M. Viollette regards these experiments as conclusive, and has instructed the prefects, from now on, whenever there is a serious shortage in the grain crop, to take the necessary action to avoid waste of the potato supply. The potato is thus given an added importance, since it is possible to utilize it in the preparation of bread.

Marriages

Major Norman Thomas Kirk, M. C., U. S. Army, Fort Oglethorpe, Ga., to Miss Anna M. Duryea of New York City, at Fort Oglethorpe, Ga., September 21.

Capt. Harry Munn Godfrey, R. A. M. C., Charlottetown, P. E. I., to Miss Margaret W. Hawley of Brookline, Mass., in Boston, September 18.

Francis Dudley Buck, M.D., New York City, to Miss Clara B. Moody of East Northfield, Mass., in Brooklyn, September 18.

Marc Ray Hughes, M.D., St. Louis, to Mrs. Rosalie N. Livingston of Lake Crystal, Minn., at Edwardsville, Ill., September 20.

Francis Marion Pottenger, M.D., Monrovia, Calif., to Miss Caroline Margaret Lacy of Pasadena, Calif., September 14.

Lieut. William Washington Vaughan, M. C., U. S. Army, Manila, P. I., to Miss Mela K. Fairchild, at Manila, July 13.

Francis Bonneau Johnson, M.D., Charleston, S. C., to Mrs. Ritchie McGann of Washington, D. C., September 11.

Philip Edward Stangl, M.D., Paynesville, Minn., to Miss Josephine Friberg of St. Paul, in Chicago, September 13.

P. A. Surg. Harry Lee Brown, U. S. Navy, to Miss Hazel Robinson of Lewiston, N. Y., September 1.

Eerko Samuel Aeilts, M.D., Forreston, Ill., to Miss Grace Engle of McKee, Ky., August 18.

A. Lovett Dewes, M.D., to Miss Margaret Dakin, both of Haverford, Pa., September 15.

Deaths

William Conner Shaw, M.D., Pittsburgh; Bellevue Hospital Medical College, 1872; aged 71; formerly a Fellow of the American Medical Association; a member of the Medical Society of the State of Pennsylvania, and the American Academy of Medicine; attending physician to Bethesda Hospital since 1889; physician to the Pittsburgh Free Dispensary from 1876 to 1882; for ten years surgeon to Mercy Hospital; died at the Allegheny General Hospital, September 18.

Lieut. Matthias Miller Wagner, M. R. C., U. S. Army, Albion View, Signal Mountain, Tenn.; University of Tennessee, Nashville, 1898; aged 41; a Fellow of the American Medical Association; on duty at Fort Story, Cape Henry, Va.; was drowned while swimming at Cape Henry, September 18.

Morey Charles Collier, M.D., Painted Post, N. Y.; Albany (N. Y.) Medical College, 1906; aged 38; a Fellow of the American Medical Association; formerly health officer of Corning, and visiting physician to the Corning Hospital; died at his home, September 16, from cerebral thrombosis.

Samuel B. Growdon, M.D., Cherokee, Okla.; Kentucky University, Louisville, 1902; aged 56; formerly a Fellow of the American Medical Association; a member of the Oklahoma State Medical Association, and president of the Alfalfa County Medical Society; died at his home, August 9.

Thomas Jefferson Lee, M.D., Rocky, Okla.; Vanderbilt University, Nashville, Tenn., 1883; aged 56; formerly a Fellow of the American Medical Association; a member of the Oklahoma State Medical Association, and a member of the council; died at his home, August 6.

John Earhart Morris, M.D., Indianapolis; Medical College of Indiana, Indianapolis, 1896; aged 48; formerly a Fellow of the American Medical Association; associate professor of surgery in the Indiana School of Medicine, Indianapolis; died at his home, August 25.

John A. Staral, M.D., Cleveland; Western Reserve University, Cleveland, 1904; aged 36; a Fellow of the American Medical Association; assistant in the tuberculosis dispensary in his alma mater; died in the Lakeside Hospital, Cleveland, September 17.

Alfred De Carre, M.D., Washington, D. C., George Washington University, Washington, D. C., 1889; aged 67; a veteran of the Franco-Prussian War; for many years an employee of the Treasury Department; died at his home, September 16.

Charles Gennerich, M.D., New York City; New York Homeopathic Medical College, New York City, 1896; aged 42; formerly professor of orthopedic surgery in the New York Medical College and Hospital for Women; died at his home, September 14.

Charles J. Ocasek, M.D., Chicago; Rush Medical College, 1893; aged 47; a well known Bohemian physician; while crossing the street, September 27, was struck by a streetcar and died in the ambulance while being taken to the hospital.

Harriet Scudder Mason, M.D., West Brighton, N. Y.; Eclectic Medical College of the City of New York, 1899; for sixteen years house physician of the Little Mother's Aid Association of New York; died at her home, September 17.

William Augustus Muhlenberg Schnecker, M.D., New York; Columbia University, College of Physicians and Surgeons, New York, 1899; aged 40; a member of the Medical Society of the State of New York; died at his home, September 13.

Charles Franklin Wackenhuth, M.D., Picture Rocks, Pa.; Western Pennsylvania Medical College, 1892; aged 56; a member of the Medical Society of the State of Pennsylvania; died in the Williamsport Private Hospital, September 13.

Edson Card, M.D., White Plains, N. Y.; Columbia University, College of Physicians and Surgeons, New York, 1882; aged 61; a member of the Medical Society of the State of New York; died at his home, September 9, from apoplexy.

Prementer Mullinix, Greencastle, Ind. (license, Indiana, 1897); aged 82; formerly a member of the Indiana State Medical Association; for many years a druggist; died at the home of his daughter, in Sioux City, Iowa, September 16.

Lacy Kindred Bobo, M.D., Maquoketa, Iowa; University of Louisville, Ky., 1889; aged 56; formerly a member of the Iowa State Medical Society; died at the home of his sister in Dallas, Texas, September 20, from cerebral hemorrhage.

John Milton Grosvenor, M.D., Middleton, Mass.; Dartmouth Medical School, Hanover, N. H., 1864; aged 78; assistant surgeon of volunteers during the Civil War; a manufacturing chemist; died at his home, September 21.

Howard W. Bassett, M.D., Richmond, Va.; Chicago Homeopathic Medical College, 1889; Medical College of Virginia, Richmond, 1906; aged 55; died in the Tucker Sanatorium, Richmond, July 15, from cerebral hemorrhage.

Thomas G. Boorman, M.D., Celina, Texas; Memphis Hospital Medical College, Memphis, Tenn., 1900; aged 53; a member of the Texas State Medical Association; died at a sanatorium in Terrell, Texas, September 12.

Lieut. Benjamin W. J. Worrall, U. S. Navy, Kansas City, Mo.; University of Kansas, Lawrence and Rosedale, 1906; aged 38; was instantly killed in an automobile accident at North Tonawanda, N. Y., September 15.

J. H. Williford, M.D., Dawson, Ga.; Cincinnati College of Medicine and Surgery, 1874; aged 65; formerly a member of the Medical Association of Georgia; died suddenly from heart disease at his home, September 11.

William Francis Brady, M.D., Scranton, Pa.; Jefferson Medical College, 1884; aged 53; formerly a member of the Medical Society of the State of Pennsylvania; died at his home, September 18, from angina pectoris.

Frederick Whittlesey Peck, M.D., New Britain, Conn.; Cleveland University of Medicine and Surgery, 1897; aged 50; died in the New Britain General Hospital, September 10, after an operation on the intestines.

Samuel G. Wishard, M.D., Watonga, Okla.; Western Reserve University, Cleveland, 1874; aged 74; formerly a member of the Oklahoma State Medical Association; a veteran of the Civil War; died early in August.

I. O. Kemberling, M.D., Colon, Mich.; Homeopathic Hospital College, Cleveland, 1873; aged 76; a veteran of the Civil War; for twenty-eight years a practitioner of Detroit; died at his home, about September 14.

Myron Dwight Gray, M.D., Cambridge Springs, Pa.; University of Pennsylvania, Philadelphia, 1874; aged 65; formerly a member of the Medical Society of the State of Pennsylvania; died recently at his home.

Benjamin Maltby Page, M.D., Pasadena and Redondo Beach, Calif.; College of Physicians and Surgeons in the City of New York, 1[illegible]4; aged 74; died in his summer home, at Redondo Beach, September 16.

William Izard Bull, M.D., Charleston, S. C.; Medical College of the State of South Carolina, Charleston, 1860; aged 79; a surgeon in the Confederate Army during the Civil War; died at his home, July 29.

Pramath Nath Roy, M.D., Boston; University of Glasgow, Glasgow, Scotland, 1885; aged 58; for many years surgeon of the Allan Steamship Line; died at his home, September 5, from heart disease.

Augustine B. Libby, M.D., Smyrna Mills, Me.; Baltimore University School of Medicine, Baltimore, 1894; aged 60; a member of the Maine Medical Association; died at his home, about September 7.

Joseph Charles Myers, M.D., Clinton, Ill.; Miami Medical College, Cincinnati, 1880; aged 59; a Fellow of the American Medical Association; died at his home, September 19, from heart disease.

John J. Weitzman, M.D., Detroit; Michigan College of Medicine and Surgery, Detroit, 1901; aged 38; died in Harper Hospital, September 16, after an operation for appendicitis.

Albert L. Bingham, M.D., Williston, Vt.; University of Vermont, Burlington, 1875; aged 64; a member of the Vermont State Medical Society; died at his home, August 7, from diabetes.

Abner Toothaker Wells, M.D., Kendallville, Ind.; Baltimore University, 1899; aged 42; a member of the Massachusetts Medical Society; died, August 17, in Little Rock, Ark.

Frederick Bernard Baurichter, M.D., Cincinnati; Cincinnati College of Medicine and Surgery, Cincinnati, 1898; aged 41; died in Christ Hospital, September 3, following an operation.

Charles Oliver Sahler, M.D., Kingston, N. Y.; College of Physicians and Surgeons in the City of New York, 1878; aged 63; died in his sanatorium in Kingston, September 17.

Michael O'Farrell, M.D., Shawnee, Ohio; Bellevue Hospital Medical College, 1876; aged 66; for forty-one years a practitioner of Shawnee; died at his home, September 14.

Carlos de Campos, Jr., M.D., Paulista, Brazil; Hahnemann Medical College, Philadelphia, 1917; aged 21; died, September 11, in the Hahnemann Hospital, from pneumonia.

George W. Ling, M.D., Dutton, Ont.; University of Michigan, Ann Arbor, 1864; University of Victoria College, Coburg, Ont., 1866; died at his home, about September 18.

Thomas Henry Hannan, M.D., Hoosick Falls, N. Y., Bellevue Hospital Medical College, New York, 1891; aged 50; died at his home, July 27, from insolation.

Charles E. Triplet, M.D., Morocco, Ind.; Kentucky School of Medicine, Louisville, 1856; aged 82; a veteran of the Civil War; died at his home, August 28.

Benjamin Sturgis Van Zile, M.D., New York; Bellevue Hospital Medical College, 1875; aged 72; died at his home, September 3, from senile debility.

James Lang, M.D., Pasadena, Calif.; Bellevue Hospital Medical College, New York, 1879; aged 86; died at his home, September 7, from senile debility.

Benjamin Franklin Stark, M.D., Lyerly, Ga.; Chattanooga Medical College, Chattanooga, Tenn., 1909; aged 31; died at his home, June 30, from enteritis.

J. F. Snyder, Hazleton, N. D. (license, North Dakota, 1899); aged 53; died at his home, August 31, from heart disease.

Thomas C. Brady, Marshalltown, Iowa (license, Iowa, 1887); aged 45; died at his home, September 1.

The Propaganda for Reform

IN THIS DEPARTMENT APPEAR REPORTS OF THE COUNCIL ON PHARMACY AND CHEMISTRY AND OF THE ASSOCIATION LABORATORY, TOGETHER WITH OTHER MATTER TENDING TO AID INTELLIGENT PRESCRIBING AND TO OPPOSE MEDICAL FRAUD ON THE PUBLIC AND ON THE PROFESSION

ZIRATOL

Report of the Council on Pharmacy and Chemistry

Ziratol (Bristol-Myers Company, New York), in compliance with the federal "insecticide law," is declared to contain 32 per cent. water and 30 per cent. glycerin as inert constituents. Regarding its active constituents the manufacturer makes the following and meaningless statement:

"Ziratol is prepared from Phenols of the Naphthalene series and consists of a solution of such Phenols in a mixture of soap, water and glycerin."

In response to inquiry, the A. M. A. Chemical Laboratory examined Ziratol and reported that its essential constituent appears to be alpha-napthol,[1] and that it has, essentially, the following composition by weight: Alpha-napthol 18 per cent., soap 20 per cent., glycerin and water sufficient to make 100 per cent.

A Ziratol advertising circular gives a tabulated report of germicidal tests, said to have been made according to the method of the Hygienic Laboratory of the U. S. Public Health Service. When this work was done is not stated. According to these tests Ziratol possesses a phenol-coefficient of 13.66. The claim that Ziratol is ten times more efficient than carbolic acid (phenol) is evidently based on this report.

These claims of high germicidal value are contradicted by an examination made for the Council. A specimen purchased in the open market was examined independently by two operators, to determine the Hygienic Laboratory phenol-coefficient. One observer found the phenol coefficient to be 2.54. The other reported it to be 3.09. Evidently the germicidal value of Ziratol is greatly exaggerated in the advertising claims and, in fact, does not exceed that of the official compound solution of cresol (Liquor Cresolis Compositus, U. S. P.) for which a phenol-coefficient of about three has been established. (See New and Nonofficial Remedies, 1917, p. 82.) The claim that Ziratol is "the Universal Antiseptic and Germicide" is manifestly an unwarranted exaggeration.

The referee in submitting this report to the Council recommended that Ziratol be held in conflict with Rule 1 (secrecy of composition) and Rule 6 (unwarranted and exaggerated claims). After the report had been submitted, it was found that a new advertising circular, accompanying a trade package, no longer contained the claim that "Ziratol is ten times more efficient than Carbolic Acid." The older circular made the following statement:

> "1. Strong Activity.—Compared with the bactericidal action of Carbolic Acid by the method of the Hygienic Laboratory of the Marine Hospital Service, ZIRATOL has the Carbolic Acid Coefficient of more than TEN, that is, ZIRATOL is TEN times more efficient than Carbolic Acid,—a strength unapproached by any other of its class. ZIRATOL in dilution of 1:1400 kills the Typhoid Bacillus in 2½ minutes, thus proving that it is strongly active even in very weak solutions."

The new advertising circular reads:

> "1. Strong Activity—Extensive bacteriological investigations on many pathogenic organisms, conducted in the Lederle Laboratories of New York, prove conclusively the high bactericidal value of Ziratol in extremely dilute solutions. (A copy of the complete report will be mailed upon request.)"

In response to a request, the Bristol-Myers Company sent a copy of the bacteriologic investigations of Ziratol, said to have been made by the Lederle Laboratories. The organisms employed for these tests were *Staphylococcus aureus*, *Staphylococcus albus*, *Streptococcus*, Green pus bacillus, *B. coli*, and saliva. No tests are given with the typhoid bacillus. The conclusion is reached that "*in all the tests the solutions of* Ziratol have several times greater killing efficiency than those of phenol." The "coefficients" or comparative values which can be calculated from the results after exposure of 15 minutes to the disinfectants range from 2.0 to 4.0. This is in substantial accord with the referee's findings as regards the phenol-coefficient with *B. typhosus* as the test object. While the new advertising circular avoids the former claim that Ziratol is ten times more efficient than carbolic acid, in germicidal value, it still makes the unwarranted claims that Ziratol is the "universal disinfectant."

---

[1] Alpha-napthol was also found to be the basis of the nostrum Benetol. See THE JOURNAL, April 15, 1911, p. 1128.

The Council declared Ziratol inadmissible to New and Nonofficial Remedies (1) because its composition is secret (Rule 1); (2) because the phenol coefficient, determined according to the method of the Hygienic Laboratory, U. S. P. H. S., is not stated on the label (Rule 2); (3) because the label and the circular accompanying the trade package [illegible]vises its use by the public as a "vaginal douche" (Rule 3); [illegible] (4) because the claim that Ziratol is the "universal dis[illegible]ectant" is exaggerated and unwarranted (Rule 6).

Before authorizing publication of the preceding report the Council submitted it to the Bristol-Myers Company in order to give that company the opportunity of revising its method of marketing Ziratol. In reply the company enlarged on its withdrawal (on "our own initiative") of the claim that Ziratol had a phenol-coefficient of over ten when this claim was shown to be incorrect "by authoritative sources." One wonders whether this is a euphemistic reference to the proceedings of the federal authorities under the Insecticide Act against the Bristol-Myers Company, just made public,[1] because of the false claims made for the germicidal efficiency of Ziratol. This prosecution resulted in the seizure and condemnation of two lots of this proprietary which had passed in interstate commerce.

The Bristol-Myers Company in replying to the Council's report made no offer to declare the exact composition of Ziratol, to state the actual phenol-coefficient, or to remove the other objections pointed out in the report of the Counci' In other words, the Bristol-Myers Company has abandoned a definite, but false claim of high germicidal power—a claim which subjected the firm to federal prosecution—and has substituted therefor indefinite statements which do not define the actual germicidal efficiency of Ziratol.

SOME MISBRANDED NOSTRUMS*

DeWitt's Eclectic Cure.—W. J. Parker & Co., Baltimore, Md., was the proprietor of "Dr. De Witt's Eclectic Cure," which contained alcohol, opium and ether. It was sold under the claim that it was an internal and external remedy for cholera, dyspepsia, diphtheria, croup, scarlet fever and other conditions. These claims were declared false and fraudulent. It was declared further misbranded in that while the label declared the presence of 75 per cent. alcohol and 1 grain of opium to the fluid ounce, the stuff actually contained 60 per cent. alcohol and 1.3 grains of opium to the ounce. W. J. Parker & Co. admitted the allegations of the libel. The court ordered that if the company would pay the cost of the proceedings and give a bond not to sell the stuff under claims that would bring it into conflict with the Food and Drugs Act, the 288 bottles of "DeWitt's Eclectic Cure" that had been seized might be delivered to it.—[*Notice of Judgment No. 4470.*]

DeWitt's Liver, Blood and Kidney Cure.—William J. Parker, who traded under the name the W. J. Parker Co., Baltimore, Md., sold "Dr. DeWitt's Liver, Blood and Kidney Cure" under the claim that it would cure diabetes, Bright's disease, malaria and diseases of the liver, blood and kidneys. Government chemists reported that the preparation, which contained over 11 per cent. alcohol, was essentially an alcohol-water solution bearing a cathartic drug together with Epsom salt, nitrates and iodids. The taste suggested senna. The claims made by Parker were declared recklessly and wantonly false and fraudulent. He pleaded guilty and was fined $15.—[*Notice of Judgment No. 4440.*]

Lightning Hot Drops.—This nostrum was sold by the Herb Medicine Co., Springfield, Ohio, and admittedly contained 60 per cent. alcohol and 48 drops of chloroform to the ounce. The federal chemists reported also the presence of ether and cayenne pepper. It was sold as a cure for diphtheria, bloody flux, inflammatory rheumatism, *la grippe* and all aches and pains. These claims were declared false and fraudulent and applied knowingly. The company pleaded guilty and was fined $50 and costs.—[*Notice of Judgment No. 4414.*]

Mother's Salve Mother's Remedy.—The Mother's Remedies Co. of Chicago, Ill., manufactured this preparation, which, according to the government chemists, was a green-colored salve consisting of petrolatum (vaseline) with some glycerin, potassium chlorate and oils of cloves, cinnamon, eucalyptus, sassafras and pine or juniper, together with a gum, like gum acacia, and a small amount of fatty oil. The label declared that the product was "Prepared from vegetable oils," a false and misleading statement, as, actually, it was prepared from animal, mineral and vegetable oils. It was further sold under the claim that it was a preventive of diphtheria and pneumonia, a "cure" for croup and catarrh and a remedy for eczema, piles and salt rheum. These claims were declared recklessly and wantonly false and fraudulent. The company pleaded guilty and was fined $25 and costs.—[*Notice of Judgment No. 4427.*]

Raney's Blood Remedy.—This preparation was manufactured by Leila J. Raney of Atlanta, Ga., who did business under the name of Raney Medicine Co. The government chemists reported that analysis showed the product to be a solution of potassium iodid ("potash") and corrosive sublimate in syrup of sarsaparilla with 16 per cent. alcohol. It was sold under the claim that it was a "cure" for cancer, pellagra, catarrh, female complaints and rheumatism and as a remedy for carbuncles, eczema, diseases of the kidneys, all blood and nerve diseases and was, in addition, a nerve tonic and a nerve rebuilder. These claims were declared false and fraudulent and applied knowingly, recklessly and wantonly. Leila J. Raney pleaded guilty and was fined $50.—[*Notice of Judgment No. 4436.*]

Rattlesnake Oil Liniment.—The federal authorities seized 51 bottles of "White Eagle Indian Rattlesnake Oil Liniment" charging that the product was misbranded under the Food and Drugs Act. The name was declared misleading in that it purported to state that the product contained rattlesnake oil, whereas, in fact it contained no appreciable amount, if any, of such oil. The claims on the trade package that the stuff was a positive cure for rheumatism, catarrh, diphtheria, eczema and various other conditions were declared false and fraudulent. No claimant having appeared, the court entered judgment of condemnation and forfeiture and ordered that the United States marshal should destroy the product.—[*Notice of Judgment No. 4442.*]

Rosadalis.—Hall & Ruckel, New York City, sold this preparation which, according to government chemists, was essentially a water-alcohol solution containing over 32 per cent. alcohol and 2.8 grams per 100 c.c. of potassium iodid and a cathartic drug. It was sold under the claims that it would cure all malarial impurities of the blood, consumption in its early stages, rheumatism, "female diseases," chronic diseases of the blood, liver, kidneys and bladder. These claims were declared false and fraudulent and made recklessly and knowingly. The company pleaded guilty and was fined $25.—[*Notice of Judgment No. 4505.*]

Correspondence

DRAFTING THE MEDICAL PROFESSION

To the Editor:—An editorial appeared in THE JOURNAL, Aug. 11, 1917, p. 474, concerning the selective draft of physicians. The New York State Committee of National Defense, Medical Section, after a most careful and exhaustive study, came to the conclusion that a classification of physicians in the United States should be made with selection of those whose age, physical condition, freedom from family obligation, etc., would make them available and desirable for Army service, such classification to exclude all those whose services were necessary in rural districts, hospitals, health departments and medical colleges, and that authority should be secured to furnish the former to the Army and to keep the latter at home.

The first step in this plan was to send a petition to the Council of National Defense explaining the need and advantages of a selective draft. This petition was printed in THE JOURNAL, August 25, and is now being circulated among the physicians in New York state.

Your editorial comment made this proposal appear as an effort to discredit the patriotism of the medical profession. No such thought actuated the framers of the petition. The idea was first formally proposed by the Medical Section of the North Carolina State Committee and has been approved by many prominent members of our profession.

The following statement regarding the selective draft of physicians was prepared by the secretary, Dr. F. T. Van Beuren, Jr., and gives a very clear explanation of the aims and purport of this plan.

1. The principle of Universal Service requires that every individual should serve the Nation in time of need, in that situation which best befits his age, his experience, his talents and education and his economic status.

2. It is founded on the obligation universally owed by every individual to the Nation whose protection and opportunities he has enjoyed.

3. The New York State Committee of National Defense, Medical Section, believes in and affirms this obligation and the principle of Universal Service founded upon it.

4. In war time the medical profession is faced by the duty of
   (*a*) Furnishing to the Army an adequate number of physicians fit to become medical officers.
   (*b*) Furnishing adequate medical care to civil communities at home.

5. It is obvious that, in an emergency like the present, when a large percentage of the physicians of this country are needed as medical officers for our own Army and to aid the armies of our Allies (whose available supply of new medical personnel is practically exhausted—see "London Letter" in JOURNAL A. M. A., September 8th, 1917), an orderly and efficient plan of procedure is desirable and will sooner or later become necessary. It is obvious, also, that not all physicians are fit to become medical officers.

6. To be effective then, in fulfilling the duties stated in paragraph 1, such a plan must include two essentials:
   (*a*) An adequate classification upon which to base the selection of those who are fittest for the Army and those who are most needed at home.
   (*b*) Authority to furnish the former individuals to the Army and to retain the latter at home.

7. The most efficient plan so far offered for accomplishing these essentials is the one recommended by the New York State Committee of National Defense, Medical Sections, in its Petition for Selective Draft of Physicians. It provides for:
   (*a*) A Federal classification of physicians by a special Federal Medical Census similar to the recent special Medical Census of New York State.
   (*b*) Authorizing the President to call into service and commission as medical officers an adequate number of physicians between the ages of 21 and 45 years fit for army service.

8. The selection of these individuals would be made by lot from all those determined by the classification to be available and desirable for army medical service. The selection would be in the hands of the medical profession and the quota to be furnished by each County in the United States would be based upon the number of such available physicians in that County.

The necessary authority would be delegated, in the form of Regulations, to the Surgeon General of the Army and to the County Auxiliary Medical Committee for National Defense. The Judge Advocate General has stated that the legal requirement of such a plan would be constitutional.

It is confidently hoped that when this proposal is thoroughly understood it will receive the cordial support of every red blooded physician who desires to render the most effective, intelligent and patriotic service to his country in this great emergency.

HENRY L. K. SHAW.
Major, M. R. C., U. S. Army, Madison Barracks, N. Y.

PRIORITY IN APPLICATION OF HEAT IN CORNEAL ULCER

To the Editor:—I take great pleasure in correcting an error which was made by myself in discussing the papers of Drs. Verhoeff and Shahan at the recent meeting of the Section on Ophthalmology of the American Medical Association in New York.

I participated in this discussion on the spur of the moment, after listening, with careful attention, to the various ophthalmic surgeons. It was a surprise that the authors of these papers did not mention the father of this treatment, one of San Francisco's pioneers in ophthalmology. When I began my remarks on the subject I could not recall the name of Dr. Martinache, and appealed to the audience. Dr. Park Lewis of Buffalo mentioned the name of Dr. Barkan, whom I accepted for the moment, thinking that on my return home I would look up the reference and give credit to the proper person, Dr. Martinache. Since reading Dr. Nagel's letter to THE JOURNAL, Sept. 15, 1917, p. 933, I have looked up the data on the subject and can confirm Dr. Nagel's statement, giving credit to Dr. Martinache, whom I had in mind all the time, but whose name I could not recall at the time. "Honor to whom honor is due."

L. WEBSTER FOX, M.D., Philadelphia.

A SELECTIVE DRAFT OF PHYSICIANS BASED ON CLASSIFICATION

To the Editor:—After reading the communication of Major Derby on this subject (THE JOURNAL, Sept. 22, 1917, p. 1023), I cannot refrain from writing a few words.

Major Derby is most inconsistent in saying the Army wants the best men of the profession and the younger men. We all know that the youngest men are not the best men of the medical profession. They have not had time to become the best men. And it certainly is cruel and unjust to speak of men who have given up everything—homes, families, profession and incomes ranging from five to twenty times what the government is paying them—as failures and an inferior lot. Certainly, judging from the men who have gone from this part of the country, Major Derby is a very poor judge of the profession and of men.

MRS. C. J. COMBS, Oshkosh, Wis.

To the Editor:—In THE JOURNAL, Sept. 22, 1917, I see a criticism of the Medical Reserve Corps from Richard Derby, Major, M. R. C. At Fort Riley, Kan., we have specialists in all lines of the medical profession, a very few men having just finished an internship at some hospital, and a few men just out of college a year or two. But 90 per cent. of the men here are good men, who have been taking care of the sick and wounded from five to twenty-five years, have been successful both professionally and financially, and have sacrificed home comforts and incomes of from $2,000 to $20,000 a year. If these men can take care of the sick and wounded men at home I do not see why they are not capable of taking care of sick and wounded men in the Army.

Most of the good men under 30 that Major Derby speaks of are the ones that have made a *financial failure* of their profession. They are staying at home trying to get a practice by the other man's sacrifice. If Major Derby has a fair proportion of the men described in his company, I am glad that I do not belong to his company.

D. E. KISECKER, First Lieutenant, M. R. C.,
Fort Riley, Kan.

Responsibility.—Responsible behavior depends more on sound morals than anything else, and sound morals are sound habits due to sound parentage and a wholesome environment. —George Frederick Arps, *Scientific Monthly.*

Queries and Minor Notes

Anonymous Communications and queries on postal cards will not be noticed. Every letter must contain the writer's name and address, but these will be omitted, on request.

APPARATUS FOR SPRAYING PARAFFIN

To the Editor:—Can you tell me where I can get apparatus for spraying paraffin on burns?

J. Mortimer Crowe, M.D., Watertown, N. Y.

Answer.—The Caldwell Sprayer (described in The Journal, Aug. 4, 1917, p. 383) and the Pierce Paraffin Sprayer are marketed by the Max Wocher and Son Company, Cincinnati. The Abbott Laboratories of Chicago list an atomizer for melted wax. Also the DeVilbiss Manufacturing Company, Cleveland, makes an instrument for this purpose.

MEDICAL ITALIAN-ENGLISH BOOKS

To the Editor:—Can you inform me whether there are any special textbooks I could obtain or the purpose of acquiring a speaking vocabulary of medical Italian, such as would be of service to a physician practicing among Italian people?

Philip Katzen, M.D., Brooklyn.

Answer.—

Book Notices

The Sex Worship and Symbolism of Primitive Races: An Interpretation. By Sanger Brown, Jr., M.D., Assistant Physician, Bloomingdale Hospital. With an Introduction by James H. Leuba. Cloth. Price, $3 net. Pp. 145. Boston: Richard G. Badger, 1916.

This book, the greater part of whose first three chapters appeared in the *Journal of Abnormal Psychology*, was written with the object of giving the life history of a primitive motive in the development of the race, and to emphasize the dynamic significance of the motive. In the first chapter, on "Simple Sex Worship," the author shows that a simple form of sex
worship has been quite generally found among the
races of mankind. "In the frank and open form of
ship, it is quite clear that we are dealing with a ver
type of mind." In the next chapter, on "Symbolis
author says, "As civilization advanced the deification
was no longer frank and open. It came to be carried
means of symbolism." He gives an account of var
symbols to illustrate the wide prevalence of sex wors
among primitive races, and to give a certain insight into t
type of mind which evolves symbolism. In the third chapte
on "Sun Myths, Mysteries, and Deca Sex Worship," the
author discusses the decadence or of this worship,
which occurred after peopl wn these simple
religious conceptions. der, on "Interpreta-
tions," the author anal ur the worship of sex.
He draws a paralleli —[*Notic* worship, actuated by

Liability of Employers for Services Rendered to Injured Employee

(Perkins vs. Kilpatrick et al. (Mo.), 193 S. W. R. 876)

The Kansas City (Mo.) Court of Appeals, in affirming a judgment in favor of the plaintiff for services rendered to an injured employee of the defendants, contractors in a quarry for furnishing rock to a railway company, says that the defendants relied much on the difference in a request for service from a physician and a request for other character of employment. If one is found in distress or serious sickness or injury, so that he is unable to care for himself, and is seen to be without professional help, it is the instinct of humanity for one observing such dire situation to call a physician; and it is not thought or expected, either by the physician or the one calling him, that a liability for services is incurred. But this case was more than that. When this employee was injured he was placed in a shanty nearby, and the defendants' regularly employed physician was put in charge of him. He remained there for two days, when the defendants' manager or superintendent sent him to a hospital where the plaintiff was a surgeon and had charge of patients, besides which he was division surgeon for the railway company and first knew of the injured man through its superintendent. The plaintiff began attendance on the man the day of his arrival at the hospital, and kept up his service for nearly two years; the defendants' physician having no part therein. During all this time the defendants knew of the serious injury the man had received. They knew of his removal to the hospital, and, of course, of their obligation to him. The court thinks this was a strong circumstance against their denial of liability, properly weighed by the jury. When the railway company learned that the man was not its employee, its superintendent caused its manager at the quarry to seek information concerning the defendants' liability for the plaintiff's services. The manager subsequently received a letter from "Kilpatrick Bros., by W. C. Rich," saying: "Replying to yours of the 16th inst. You may bill on us to cover the expense of the hospital treatment in connection with the case of Benjamin Funk, the man who was injured," etc. There were but two ways to avoid this letter; one to deny Rich's authority, and the other to insist that it could not affect the plaintiff's claim except for the services after its date. Rich was shown to be the defendants' timekeeper, but it was also shown that he signed checks, attended to correspondence, and signed letters for the defendants. There was abundant room for the jury to find authority. The letter, connected with the other evidence, was ample to show a liability for the plaintiff's services, not merely from the date of the letter, but the whole service. The court agrees with the defendants that the mere fact that they collected a fund out of the wages of employees would not necessarily make them liable to the plaintiff or any other particular persons for services. But it was a proper circumstance to be considered by the jury. The question in the case was essentially one of fact, and the court thinks it was shown by abundant evidence, the circumstances considered, that the defendants knew of their obligation to the plaintiff, and through their accredited agent promised to pay him.

Without Power to Compel Vaccination

(Waldschmidt et al. vs. City of New Braunfels et al. (Tex.), 193 S. W. R. 1077)

The Court of Civil Appeals of Texas reverses a judgment obtained by the defendants, and in its stead renders one that they be enjoined from excluding from the public schools of New Braunfels the children of plaintiff Waldschmidt because they had not complied with a city ordinance requiring a certificate of vaccination for admittance to schools, said plaintiff and children being Christian Scientists. That the state, through its legislature, may, in the exercise of its police power, enact all reasonable legislation for the promotion of the public welfare, including the preservation of health, the court says is too well settled to require citation of authorities. Also that the reasonableness of such measures is primarily a question for the legislature, and will be reviewed by the courts only in clear cases of abuse of such power, is equally well settled. In reference to this rule, as applied to vaccination, courts have frequently said that they were not called on to decide whether or not vaccination was a preventive of smallpox, but only whether the legislature which enacted such legislation had reason to so believe. But the rule is quite different where local authorities have undertaken to pass rules or ordinances with reference to vaccination, without being expressly authorized so to do. Municipal corporations are the creatures of statute, and have no powers except those expressly or impliedly granted by the statute creating them.

The legislature of Texas has never enacted a law to exclude any one from school who has not been vaccinated, nor has it expressly authorized any city council, board of school trustees, or even the state board of health, composed as it is of eminent physicians, to do so. The power to pass the ordinance above referred to is not to be implied from article 838 of the revised statutes, which reads: "To do all acts and make all regulations which may be necessary or expedient for the promotion of health or the suppression of disease." That means only that city councils may "do all acts and make all regulations which may be necessary or expedient" to carry into effect the powers expressly granted them "for the promotion of health or the suppression of disease." Anything that they might do in attempting to carry into execution the powers expressly granted would be sustained by the courts, unless it was clearly shown to be unreasonable. Moreover, the court thinks that the compulsory education law, with its penalty of fines, furnishes another reason, and a cogent one, why it should not be held in Texas that city councils have implied authority to exclude from public schools all who have not been vaccinated. A number of exemptions and excuses are provided for in the act, among which is quarantine, but failure to have been vaccinated is not one of them.

That the state may disregard religious opinions when necessary so to do to protect morals is the effect of the decisions in reference to polygamy as taught by the Mormon church. Whether or not this would apply to compulsory vaccination, the court is not called on to decide. The state has not attempted, either directly or indirectly, to compel any one to be vaccinated, nor has it authorized any municipal corporation to do so.

If, however, it be conceded that the city had implied authority to pass and enforce the ordinance at the time of its passage, such authority arose from the prevalence of smallpox in the city in epidemic form, or its threatened invasion at that time. Courts so holding limit such authority to the continuance of the emergency. So the question was: What was the condition in regard to smallpox in the city when this case was tried? The undisputed testimony showed there was then but one case of smallpox in the city, and it was isolated and practically convalescent. That a portion of the population was Mexican, and that smallpox was of frequent occurrence in San Antonio, 28 miles distant, would not justify the enforcement of the ordinance. A rehearing was denied.

35 *Id. Vital Capacity of Lungs and Its Relation to Dyspnea. F. W. Peabody and J. A. Wentworth, Boston.—p. 443.
36 *Id. Basal Metabolism and Minute-Volume of Respiration of Patients with Cardiac Disease. F. W. Peabody, J. A. Wentworth and B. I. Barker, Boston.—p. 468.

28. **Etiology of Rat Bite Disease.**—The two types of spirochetes, found by Kitagawa and Mukoyama in the guinea-pigs and rat, respectively, not only varied considerably with respect to size, but also showed differences with regard to the distinctness of the spirals and the pointedness of the ends, which facts seem to us to indicate that these spirochetes belong to two different species. Yet, since the staining brought out no definite distinctions between them, and as they showed practically the same number of curves, it appears possible that the above mentioned difference of form was a result of the differences existing between the inoculated animals, or that the spirochetes may have been in different stages of development. At all events, it is interesting to note that the spirochetes obtained from inoculation with the lymph gland and the lymph plasma derived from the same patient also appear to be of different sizes. Whether Type A and Type B are really identical, or, if they are not, which one is the etiologic agent, are points which must be determined.

29. **Salicyl Edema.**—It is claimed by the authors that the anuria produced by the administration of full therapeutic doses of salicylate is due to retention of water as indicated by an increase in body weight unless modified by diaphoresis. This retention is demonstrable about twenty hours after the start of administration of the salicylate and persists until the salicyl excretion is completed, that is, about eighty hours (three and one-third days). The retention occurs chiefly in the tissues, for no dilution of the blood is demonstrable by estimations of hemoglobin. The edema is accompanied by a diminution in phenolsulphonephthalein excretion together with an accumulation of urea nitrogen of the blood, and increased excretion of albumin, all of these elements reaching their previous levels with the disappearance of the edema. There is, therefore, a diminution in renal functional efficiency, and since this generally makes its appearance before an actual increase in body weight is demonstrable (edema) and later coincides with it, it seems that the renal factor plays an important rôle in the production of the edema. These phenomena are not modified by the administration of sodium bicarbonate together with the salicylate, and in doses sufficient to maintain the urine alkaline.

32. **Effect of Undernutrition on Muscular Force.**—Williams' investigation supports the common clinical observation that diabetics, as a rule, are distinctly physically weaker than normal persons. Loss of body musculature may partly explain this, but it is probable that the lessened amount of food metabolized in these cases does not provide sufficient energy for the normal exercise requirements of the body. There appears to be a direct relationship between food tolerance and muscular vigor. As food tolerance increases, so does also muscular tone. Decline in food tolerance is accompanied by loss of physical vigor. The continued use of a low diet for many months, even though it fall far short of the energy requirements of the body, provided it is within the physiologic limitations of the body to metabolize it, will cause an appreciable gain in muscular tone, although the amount of physical effort that such a person may be able to put forth may be considerably below normal. These observations also show that while diabetics living on a diet below normal physiologic requirements possess a diminished muscular vigor, feeding them beyond their metabolic limitations causes not only a further reduction in their tolerance for food, but also an even greater loss of strength. This is contrary to the view commonly held by both physicians and laymen. There is no justification for the common notion that overfeeding causes even a temporary increase in comfort or body strength. The general conclusion from this inquiry is that diabetics gain in physical vigor as they become and remain sugar free, while overfeeding causes a definite and often a serious loss of strength. Attention is called to the use of the dynamometer as a simple and fairly trustworthy method of measuring muscular tone or physical vigor.

33. **Auricular Flutter.**—A case is presented by Heard and Strauss which shows most of the well known characteristics of auricular flutter. The contour of the P deflection is discussed. The origin of auricular impulses is believed to be ectopic. The usual difficulties were encountered in the mea-

surement of A.-V. interval in flutter. The A.-V. interval was prolonged by digitalis in flutter as in normal mechanism. Emphasis is laid on the variation of auricular rate as found in the individual case of flutter, a fact which has been usually overlooked. Blood pressure studies showed marked daily variation of the systolic pressure as observed during flutter and fibrillation. There was a marked constancy of the diastolic pressure. Vagus stimulation by pressure, either over carotid artery or eyeball, produced ventricular slowing or standstill, as has been noted by previous observers. Vagus stimulation produced like results in fibrillation and in flutter. The prolongation of the refractory stage of heart muscle under the influence of repeated stimuli is noted as a possible explanation of the auriculoventricular dissociation in flutter and fibrillation. Finally, the effect of digitalis during treatment—its very early effect on conduction, its possible effect on auricular rate, the change in the T wave, and the large amount necessary to change the mechanism to fibrillation—is considered at some length.

35. **Vital Capacity of Lungs and Its Relation to Dyspnea.**—Observations on patients with heart disease show that there is a close relation between decrease in vital capacity and the tendency to dyspnea. Compensated patients, who do not complain of dyspnea on exertion, have a normal vital capacity. Patients with more serious disease, in whom dyspnea is a prominent symptom, have a low vital capacity, and the decrease in vital capacity runs parallel to the clinical condition. Changes in the clinical condition are usually associated with changes in the vital capacity. As a patient improves, his vital capacity tends to rise, and as he becomes worse, it tends to fall. Determinations of the vital capacity in cases of cardiac disease are often of practical value as they give quantitative information as to the tendency to dyspnea, and thus, indirectly, as to the clinical condition and the reserve power of the patient. In various other diseases in which mechanical conditions interfere with the movements of the lungs, the tendency to dyspnea corresponds closely to the decrease in the vital capacity. This is, however, apparently not true of the anemias. In diseases in which dyspnea is not a prominent symptom the vital capacity is usually within the normal limits, although general weakness and old age may cause a slight decrease.

36. **Basal Metabolism and Respiration of Patients with Cardiac Disease.**—Observations are reported on the gaseous metabolism and pulmonary ventilation of two groups of patients with heart disease. Group 1 consists of subjects in good or fairly good condition, in whom the vital capacity of the lungs was over 60 per cent. of the normal. Group 2 consists of much more severely affected patients in whom the vital capacity was 60 per cent. of the normal or less. The basal metabolism calculated from the oxygen consumption per square meter of body surface averaged 2.5 per cent. above normal in Group 1, and 12.8 per cent. above normal in Group 2. The average volume per respiration was less in Group 2 than in Group 1, and the average rate of respiration was higher in Group 2 than in Group 1. The minute volume of air breathed averaged approximately 30 per cent. higher in the members of Group 2 than it did in those of Group 1. The relation is pointed out between the increase of the minute volume of the more seriously affected patients and the decrease in the vital capacity of the lungs. Finally it is shown that this high minute volume is a factor in the production of dyspnea in persons with severe heart disease.

42 Roentgen Diagnosis of Pathologic Gallbladder. A. W. George and R. D. Leonard, Boston.—p. 375.

38. **Treatment of Ununited Fracture of Neck of Femur by Transplantation of Head of Femur to Trochanter.**—The method considered by Brackett and New treats the femoral head as if it were a real sequestrum. The head is placed on the inner side of the top of the sawed off trochanter, and in this way the thrust is passed directly from the shaft to the head, so that there is little or no distraction strain in weight bearing, and the head has its most favorable position for a restored function. There is one contraindication. Sometimes, after joint injury, particularly in the older people, there is found a distinct osteo-arthritic change, with thinning of cartilage, as well as the tendency to overgrowths. Under these conditions, a favorable functional result could not be expected, and this operation must not be advised.

39. **Spina Bifida and Allied Malformations.**—Harmer's series includes seven meningoceles, twenty-three myelomeningoceles, three hydroencephaloceles, and one encephalocele. Twenty-three were rounded and sessile, eight rounded and pedunculated, and three flat. Twenty cases exhibited some degree of paralysis. Of these, the paralysis was increased after operation in three, it was not affected by operation in nine, and improved or cured in eight. In five of these eight the benefit was unimportant, for all died subsequently of acute hydrocephalus or meningitis. However, the paralysis which they exhibited before operation was lessened or disappeared up to the time of death. Three of these patients are still living. One patient exhibited prolapse of the rectum and incontinence of urine and feces. Now, fifteen months later, there is no prolapse, and the mother is convinced that there is increasing control of bladder and rectum. Another case exhibited sensory paralysis of both legs, motor paralysis of right foot, and prolapsed rectum before operation. The motor paralysis of the foot and the prolapse are cured but sensation in the legs is still impaired. The third case presented a myelomeningocele in the sacral region, with leaking sac and paralysis of both feet when seen twenty-four hours after birth. Operation was done at once and the child is perfectly well sixteen months later. Sixteen patients died; eighteen patients were discharged alive; a mortality of 47 per cent. The causes of death were shock, one; acute hydrocephalus, one; continued loss of cerebrospinal fluid, four; umbilical septicemia, one; meningitis, nine. Therefore, deducting the case which died of umbilical septicemia, the operative mortality is 44.1 per cent. Sixty-four and seven-tenths per cent. of the cases exhibited ulcerated or leaking sacs. Of the cases discharged alive, four exhibited some degree of paralysis, three increasing hydrocephalus, ten were well. Of the well cases, three were myelomeningoceles, all with ulcerated or leaking sacs; four were meningoceles with intact coverings, and four were encephaloceles.

40. **Results of Radium Treatment.**—Of 642 cases treated with radium, 354, or 55 per cent., received definite benefit.

52 Case of Placenta Praevia in Twin Pregnancy. M. Rosensohn, New York.—p. 200.

46. **Accidental Hemorrhage from Premature Separation of Placenta.**—Among 100,000 confinements at the New York

Lying-In Hospital premature separation of the placenta took place in 254 cases, the accident occurred twice as frequently in multiparae as in primiparae. In the 152 instances of marked hydramnios in the 100,000 labors, premature separation of the placenta occurred but three times; in 1,478 cases of twins premature separation of the placenta occurred but four times; in twenty-nine cases of triplets it occurred twice. In five instances of premature separation there was evidence of an antenatal infection with elevation of temperature and a foul odor to the uterine contents when delivered. External trauma was a feature in fifteen cases, fibroids in three and a short cord in two. Twenty-two deaths occurred in the 254 cases, a maternal mortality of 8.66 per cent. The mortality was considerably higher in the so-called "concealed" hemorrhage cases. There were twenty-four cases of disruptive concealed hemorrhage with six deaths, a mortality of 25 per cent. Eighteen of these, however, showed some external bleeding as well. In the six with absolutely concealed hemorrhage of the disruptive type but one died, and this one apparently died of an accompanying eclampsia. There were 133 stillbirths, a fetal mortality of 50.8 per cent. in the 262 babies born. Thirty infants died in the first ten days, making a total fetal and infantile mortality of 62.2 per cent. In the concealed hemorrhage group the only child that survived was delivered by cesarean section.

As to the treatment and method of delivery of these 254 cases of accidental hemorrhage; sixty-eight delivered themselves spontaneously after simple rupture of the membranes, with two late deaths, both due to infection; twenty-seven delivered themselves spontaneously after the insertion of a cervicovaginal packing of iodoform gauze, with no deaths; eight spontaneously after the use of a Voorhees bag with one immediate death, due to hemorrhage and eclampsia. Version was performed eighty-one times with ten maternal deaths. It was done fourteen times after cervicovaginal packing, twenty-two times after manual dilatation of the cervix, and twenty times as part of an accouchment forcé. Forceps completed the delivery in twenty-nine cases with three deaths. Breech extraction was done nineteen times. Vaginal cesarean section was done five times with one death. Abdominal cesarean section was done seven times with no maternal death. The highest mortality occurred in the group of cases in which version was done after forcible manual or instrumental dilatation of the cervix. Harrar recommends in the treatment of accidental hemorrhage, rupture of the membranes in the very mild cases, rupture of membranes and the use of the cervicovaginal packing in the more severe cases, reserving the use of the abdominal cesarean section in the grave concealed hemorrhage cases with closed cervix, and doing a hysterectomy only when there is accompanying partial or complete rupture of the uterus.

104 Id. Cerebrosids of Kidney, Liver and Egg Yolk. P. A. Levene and C. J. West, New York.—p. 649.

86. **Determination of Chlorids in Blood.**—Foster found that thoroughly reliable results are obtained by applying the original McLean-Van Slyke titration to the filtrates obtained after coagulating the blood proteins with metaphosphoric acid. The additional acidity due to the metaphosphoric acid is not sufficient to interfere with the sensitiveness of the starch iodin end-point, being only about 2 per cent. of that due to

the nitric acid. The coagulum formed by the addition of meta phosphoric acid to the diluted blood or plasma is very finely divided, and the diffusion of chlorids to uniform concentration throughout the mixture is complete in ten minutes if the flask is shaken occasionally.

87. **Muscular Tissue and Urea Formation.**—The purpose of the experiments reported by Hoagland and Mansfield was to determine whether or not urea-forming enzymes are present in muscular tissue. Taken as a whole, the results show that urea formation is not an important function of muscular tissue. In view of the well established fact that the liver plays an important part in the formation of urea in the body, these findings lend support to the view that urea production is chiefly a function of that organ.

88. **Glycolysis of Muscular Tissue.**—According to Hoagland and Mansfield muscular tissue autolyzed under aseptic conditions shows appreciable glycolytic properties. Glycolysis takes place most rapidly within a comparatively few hours after the death of the animal. The glycolysis that took place under the conditions of these experiments did not result in the production of carbon dioxid. Muscular tissue apparently has the ability to synthesize carbohydrates. In part at least, and probably in their entirety, the processes by which sugars are utilized by the animal body are enzymatic in nature.

91. **Determination of Blood Sugar.**—The work done by McGuigan and Ross corroborates the work of von Hess and McGuigan, showing that the sugar in the blood reacts as it does in a water solution.

92. **Origin of Creatin.**—The authors do not offer any evidence for the methylation of glycocyamin by muscle or liver tissue in vitro. The injection of glycocyamin into rabbits and dogs may be followed by an increased excretion of creatin.

93. **Creatinuria in Normal Adults.**—In two normal women Denis and Minot were able to cause creatin excretion by feeding a high protein (creatin free) diet, and to cause the creatinuria so produced to disappear by the consumption of a low protein diet. In two men to whom a similar experimental procedure was applied the authors were unable to produce creatin excretion even when a sufficient amount of protein was consumed to cause the urinary nitrogen to rise to 34.5 gm. per day.

94. **Effect of Tethelin on Early Growth.**—From the total lack of effect of the administration of tethelin to the mother on the growth of suckling young the authors believe that one may infer either that tethelin exerts no effect on growth during the first (infantile) growth cycle or else, which is more probable, that the tethelin administered to the mother is not secreted as such to any appreciable extent by the mammary glands of the mother. The administration of tethelin to the young subsequently to the fourteenth day, when their eyes are open and they have access to food other than that supplied to the mother, results in a noticeable acceleration of growth during the second growth cycle (second to the fifth weeks), followed on initiation of the third cycle, by a marked retardation which evidences itself despite the fact that the administration of tethelin is discontinued at the end of the fifth week.

95. **Blood Lipoids in Nephritis.**—The abnormalities in the blood lipoids in severe nephritis were found to be high fat in plasma and corpuscles and high lecithin in the corpuscles. The cholesterol values were practically normal. These abnormalities are the same as are found in alimentary lipemia and for this reason are regarded by Bloor as the result of a retarded assimilation of fat in the blood, which in turn is thought to be one manifestation of a general metabolic disturbance brought about by a lowered "alkali reserve" of the blood and tissues.

96. **Dynamics of Process of Death.**—Osterhout found that by measuring the electric conductivity of tissues placed in toxic solutions the process of death can be followed in the same manner as the progress of a reaction in vitro. Death proceeds as a monomolecular reaction which is somewhat inhibited at the start. This is easily explained if consecutive reactions are involved in the process of death. This explanation also applies to many other cases of toxic action. In all these cases death behaves as a reaction which is continually going on and which is accelerated by the toxic agent.

105. **Periarteritis Nodosa.**—Two cases of periarteritis nodosa are added by Klotz to the forty cases previously recorded in the literature. The first case was a woman 33 years of age, whose past history does not bear on her final illness. Syphilis was not considered as a possible factor, so that a Wassermann was not performed. Her final illness was of four weeks' duration, beginning with a severe cold following exposure to inclement weather. Muscle and joint pains were prominent, and subsequently these were followed by severe, cramp-like pains in the abdomen. She ran a continuous temperature over 100 F. There was some leukocytosis and albuminuria and slight icterus. Death occurred suddenly in collapse. The necropsy revealed the typical lesions of periarteritis nodosa with aneurysms and thromboses distributed along the hepatic and cystic arteries. Rupture of one of these hepatic arteries led to extensive hemorrhage about the liver and into the peritoneum. There were no other serious acute lesions nor were there any infectious deposits about the heart.

The second case occurred in a man 53 years of age, who previously had suffered considerable illness. He had had acute rheumatic fever. His present illness began after an exposure to rain and cold, from which he was slow in recovering. During his illness he developed tonsillitis, which in a few days was followed by the appearance of bluish nodules in the skin. Dyspnea and cyanosis were evident throughout his illness, apparently associated with an old cardiac lesion. His Wassermann reaction was positive. He had quite a marked anemia, with some leukocytosis. From the time of the onset of his tonsillitis, he ran a continuous through irregular temperature over 100 F. During life one of the skin nodules was removed, but a diagnosis of the arterial lesion could not be made owing to the rather extensive disintegration and hemorrhage which occupied the area excised. Cultures from these nodules were negative, as were also the blood cultures. Clinical manifestations of an intra-abdominal condition were not apparent. The patient died rather unexpectedly, although during the last week of his illness, he was becoming progressively weaker. His total illness extended over a period of about three months. It is evident that the patient was primarily suffering from a cardiac lesion of not uncommon type, and that the acute periarteritis was an associated complication superadded to his other illness.

106. **Vaccine Treatment of Bronchial Asthma.**—The fifteen patients who were treated by Walker are placed into three groups: Group I, six patients whose serums agglutinated strains of *S. pyogenes-aureus* in a high titer, and for this reason these patients were treated with stock vaccines of this organism; Group II, six patients who were treated with a diphtheroid vaccine because this type of organism was the predominating one in their sputums, and because there was

no positive evidence in favor of any other kind of treatment; Group III, contains three patients who show that conditions or diseases quite remote from bronchial asthma may play some part in the cause of bronchial asthma, or at least may produce symptoms which simulate bronchial asthma. All of the patients of Group I were relieved of asthma and all associated symptoms by stock vaccine of *S. pyogenes-aureus.* Only one patient of Group II was relieved by diphtheroid vaccines. Of Group III one case was associated with hernia, and relief from the hernia by operation was accompanied by relief from asthma. A second case was associated with pituitary disease. The history of the third case would suggest a diagnosis of bronchial asthma and the administration of epinephrin relieved the symptoms. Walker points out that it is quite possible that so-called bronchial asthma in patients who are sensitive to proteins is not true bronchial asthma; it is evident that cardiac, renal, pulmonary and pituitary disease all may cause symptoms which simulate bronchial asthma.

107. **Origin of Blood Platelets.**—On the basis of a careful examination of the blood of one case Emmel states that the structural changes undergone by many of the red blood corpuscles in anemic blood are such as to be especially conducive to the production of the conditions which have been described as demonstrating the origin of blood platelets from erythrocytes. In such cases a mass of blood platelets may become adherent to the surface of the erythrocyte, the contents of the corpuscles are displaced to one side with a consequent production of a very thin transparent area in the region of contact. These conditions, together with an occasional rupturing of the weakened membrane in this region during the preparation of the material, produce the deceptive appearance of a dehiscent erythrocyte extruding blood platelets. In normal blood, in which the erythrocytes are more stable in form and structure, the so-called eviscerating corpuscles are not so obviously in evidence.

109. **Bacteriology of House Fly.**—Certain bacteria which might be of importance in the spread of infectious disease were isolated by Scott from the bodies and intestinal tract of flies. Other bacteria, while of themselves not pathogenic under normal circumstances, but which have been universally accepted as being indicators of dangerous contamination by excreta, were frequently found. Such organisms include the colon bacillus, indicating that the insect has recently come into contact with fecal excretions. The finding of the pyogenic cocci on flies suggests the possibility that this insect may be the agent in the transmission of suppurative organisms from man to man, and may afford an explanation of the spread of gangrene in field hospitals under war conditions. The following pathogenic organisms were isolated from these flies: *Staphylococcus pyogenes-aureus, albus* and *citreus; tetragenus, B. acidi-lactici; B. coli-communis; B. coli-communior; B. suipestifer; B. coli-anaerogenes; B. proteus-vulgaris; B. cuniculicida; Strephtococcus fecalis* and *pyogenes.*

110. **Isolation of B. Cuniculicida.**—*B. cuniculicida* was recovered by Scott from two common house flies during the course of investigations. This is said to be the first reported instance of such recovery.

111. **Bacteriologic Production of Acute and Chronic Kidney Lesions.**—With a single exception all of the *twenty-one* animals which received the intravenous injections of living cultures of *B. mucosus-capsulatus* showed either acute or chronic kidney lesions.

112. **Phagocytosis in Vivo.**—Bartlett and Ozaki found that when the leukocytes become less capable of ingesting bacteria, the phagocytic tissue cells of the lung, spleen and the liver act to a greater or less extent in a compensatory way for the deficient part of leukocytes. This fact is of great significance for the elimination of bacteria from the circulating blood. The bacteria introduced into the blood stream are chiefly detained by the spleen and liver, if the lung is excluded, where the detention of bacteria is chiefly temporary. This peculiar biologic property of the spleen and liver is, if not completely, partly lost when these organs undergo a marked degeneration. This probably depends on the lessened vitality of the macrophages present in these organs.

114. **Myeloma with Metastasis to Liver and Spleen.**—The view that true myeloma does not form metastases has been emphasized ever since the first recognition of this condition. There is, however, a small group of cases in which the tumor described seems truly to belong to the myeloma group, and in connection with which there have been found foci of identical tumor tissue at some distance from the bony involvement. A summary of such cases found in the literature is given by Pepper and Pearce and a case is reported which they believe belongs in this group. This case is of unusual interest in that no definite nodules of myeloma were demonstrable by Roentgen rays or at necropsy, and secondly, because there was found throughout the liver and spleen, which were grossly normal, a diffuse infiltration of microscopic foci of cells identical with those of the bony tumors. These findings seem to justify a claim of true metastasis formation in this case. Most of the features of this case are in close accord with the typical findings in myeloma. The male sex, the advanced age, 52 years, the nature and distribution of the pains, and the fatal outcome after a slowly progressive course are all characteristic. So also are the anemia and the Bence-Jones proteinuria. The white corpuscles were present in a proportion of 1 to 100 red blood cells and the differential count showed 21.9 per cent. myelocytes. The bones affected were those most commonly involved.

115. **Acid-Fast Organisms in Distilled Water.**—Keilty calls attention to factors not previously reported concerning acid-fast bodies and bacteria in distilled water. He divides distilled water into sterile, sterilized, clean and dirty. Sterile distilled water is free from all bacterial bodies. Distilled water may be contaminated in the still, the tank or collecting bottle, and show different types of organisms, including acid-fasts in most instances. The acid-fasts may or may not be morphologically like the tubercle bacillus. The older the distilled water is and the larger the amount of sediment present, the greater the number of acid-fasts will be found. In perfectly clean, but nonsterile distilled water acid-fasts may appear after standing for a month. Keilty concludes that in all bacteriologic work it is advisable to use sterile distilled water collected in sterile stills, tanks and bottles.

8. **Electrocardiographic Sign of Myocardial Change.**—As the result of the examination of several thousand cardiac cases Wells and Goodall have become increasingly convinced that the height of the second ventricular or T wave affords some indication of the efficiency with which the ventricles are functioning. They report two illustrative cases with a syphilitic history. One patient complained of pain in the left side, only being able to sleep when lying on the right side, pain over the sternum, slight dyspnea, and a sensation of sickness over his heart on exertion, which was increased by exercise and after meals; there was no cough or edema. The area of cardiac dulness was slightly enlarged, the apex beat being in the fifth space near the nipple line; the first sounds were weak but no murmur was audible; the pulse rate 100, blood pressure 140; he did 10,107 foot pounds of work in two minutes, there was a poor reaction to work and he showed signs of collapse. The electrocardiogram showed an absence of second ventricular or T waves in Leads 1 and 2 with inversion in Lead 3. He was treated with mercurial inunctions and steadily improved. When examined again in 1916 his pains had disappeared, the cardiac dulness was still slightly increased, but the apex beat was well within the nipple line, the first sound at the apex was flapping and short, the second reduplicated, the aortic and pulmonary second sounds were audible, the blood pressure was 118; the electrocardiogram showed well marked second ventricular waves in Leads 1 and 2 with inversion in Lead 3.

The second patient complained of dyspnea and palpitation on exertion and a constant feeling of lassitude, and said that he fainted on excitement or any overexertion. He was markedly anemic, the pulse rate was 60, volume very small; the apex beat was diffuse and almost impalpable; the area of cardiac dulness was greatly enlarged, extending from 2 inches to the right of the midsternal line to over 5 inches to the left; Roentgen-ray examination revealed a very large heart, the shadow agreeing with the limit as defined by percussion; it was obviously soft and atonic, as it was horizontally placed and seemed to be lying on the diaphragm. The first sound at the apex was very faint and flapping in character, the second sounds were audible at base and apex, no murmurs could be heard; he was not exercised, nor was his blood pressure taken, as he fainted twice during examination. His electrocardiogram showed very poorly marked second ventricular waves in Lead 1, almost absent in Lead 2 and completely so in Lead 3. He was treated with mercurial inunctions and improved. The cardiac area was reduced in size. The electrocardiogram showed well marked T waves in Leads 1 and 2, and distinct T waves in Lead 3.

9. **Treatment of Wounded Knee Joint.**—Barling analyzes 845 cases. In a very high proportion of cases excision of the wound, removal of bone when necessary, removal of any retained foreign body, irrigation of the joint and closure by suture has been followed by a perfectly satisfactory healing without further interference. The proportion of these cases requiring further intervention is 25.5 per cent., and Barling believes that free use of the joint is likely to result in a large majority of those in whom the primary operation was successful. In the group in which complete closure was not possible or was deemed inadvisable, and in which the wound was packed, the results are not so good. This group includes the worst cases of injury to the bones entering the knee joint. Here the proportion of cases in which further operative interference was required is 38.4 per cent. Very useful joint function may result in many cases. Excision of the wound, removal of bone when required, removal of foreign body, suture of the wound, if possible, and packing as an alternative in selected cases, is the program Barling recommends. In a considerable number of instances materials such as formaldehyd solution and glycerin or ether have been injected and retained in the joint cavity. A few surgeons pack the joint with urea, and favorable results were obtained. One operator makes a separate incision at some distance from the wound of entry, thus securing that at all events he drives nothing septic into the joint.

Barling questions whether it matters much what fluid is used to wash out the joint, the main advantage is the mechanical cleaning out of septic material, fibrin and blood clot; but this should be done thoroughly through a free opening; the use of cannulas for this purpose is insufficient. Barling deprecates aspiration of the joint and irrigation or injection with an antiseptic fluid and would only resort to it if the fluid showed only a low corpuscular element, a moderate polymorphonuclear count, and a sparsity of infective organisms, conditions which will rarely be found. Mere aspiration is apt to be followed by a breaking of infection through the capsule of the joint and a spread into the surrounding tissues, a grave addition to the patient's troubles most difficult to overcome. Regarding aspiration as rarely a wise measure, Barling mentions three other courses: (1) free opening up of the joint; (2) excision of the joint, and (3) amputation.

10. Treatment of Gunshot Wounds of Knee Joint.—In dealing with operative cases Gray believes that if the injury has implicated the main vessels so that the foot is already cold and dead, amputation should be done just above the knee if the wound is likely to remain fairly clean, and through the knee if sepsis is present and the condyles are undamaged. In the latter class of cases reamputation is frequently necessary, and when the condyles are left it can be done so as to provide the longest possible thigh stump. If, as sometimes happens, one or other popliteal nerve is shot away so extensively that it cannot be sutured later on, and if the bones are much soiled as well as comminuted, the probability is that primary amputation is the best course. If sepsis is well established in presence of much comminution, especially if there be gas gangrene, and the patient in low condition from hemorrhage or toxic absorption, amputation must be done. If, in less severe cases, the opposing ends of the long bones are so comminuted that smooth articular surfaces are not available, it is probably best to do primary resection in the way recommended by Fullerton. If large fragments have resulted from the injury, if the patient has been received early and is in good condition, and if one is fairly sure of getting away infective material, the patient should be given a chance. As a general rule, if the patella alone has been shattered, as happens fairly frequently, the fragments should be removed.

If possible, the synovial cavity should be closed, except for a small drainage opening, by suturing the lateral edges and aponeuroses, possibly after undercutting the synovial membrane on each side, or by loosening the suprapatellar pouch as already described. If this cannot be done, a "salt pack" should be used. The same procedure should be carried out if concomitant injury to other bones is not extensive. In considering the question of amputation, these points are of great importance: the possibility of removing or neutralizing infective material successfully, the amount and kind of comminution, the concomitant injury to vessels or nerves, and the condition of the patient. When conservative measures are decided on, the following are the most important operative details: determination of the track which leads to the depth; thorough disinfection of skin and track; careful and complete excision of external wound and track, including the edges of the wound in the synovial membrane, if possible in one piece. Pockets must not be cut into. The least little bit of infected tissue left behind may prevent success; provision of ample access to foreign bodies or comminuted surfaces in the joint.

Careful removal, under direct vision whenever feasible, of all foreign material, whether free in the joint or embedded in the articular surfaces. Closure of the wound in layers, using fine catgut for the synovial membrane. Drainage tubing should not project into the joint. If the wound in the synovial membrane cannot be closed, a small "salt pack," separate from any other which may be required for the rest of the wound, should be inserted firmly "down to but not into" the joint, and should be left until it is absolutely loose. Tendinous or ligamentous structures exposed during operation should be covered by skin and subcutaneous tissue; otherwise they are very apt to slough, and this postpones closure of the wound, and therefore prolongs convalescence. If there is much effusion into or from the joint, of whatever nature, or if raw surfaces, whether of bone or soft tissue, are left in the joint, at the end of operation, a tube should always be inserted "down to but not into" the synovial cavity. The injection of ether, formaldehyd solution, glycerin, or hypertonic (5 per cent.) saline solution into closed joints, is of doubtful value. They are all irritants.

12. Id.—In dealing with wounds of the knee joint Page urges that the natural defensive powers of the part against infection should be borne in mind. Primary prophylactic (that is, within twenty-four hours of injury) operations should be radical, and secondary operations undertaken on account of progressing infection, should, short of amputation, be planned on conservative lines. The expectant treatment of wounds of the knee joint is only justifiable in the case of typical perforating injuries due to a rifle bullet. All wounds of the joint caused by shell fragments or distorted bullets should be considered as primarily infected. The primary prophylactic treatment should consist in the removal of any foreign bodies present and in the excision of the whole wound track at the earliest possible time after injury. The results at present are particularly bad in cases in which gross comminution of the diaphyses is present. A primary excision or erasion of the joint (within twenty-four hours) would probably improve the results in such instances by preventing the development of entomyelitis. Repeated aspiration of the joint and the intra-articular injection of any of the antiseptics in common use are calculated to prejudice the natural defense. It is safest to leave for a few days some drainage along the wound track after operation, certainly when bone injury is present. Any infection then left may become localized in the same way as occurs in the case of the peritoneum. A gauze wick makes a satisfactory form of drain. Immobilization of the joint during all critical periods is essential. An interrupted plaster-of-Paris splint affords the best means of effecting this. When general infection of the joint has taken place treatment by fixation, lateral arthrotomy and immunization gives the best chance of saving the limb. Secondary abscesses are to be expected, and should be evacuated after their complete development. Neither cross section and flexion of the joint or secondary excision of the knee are sound procedures.

15. Physiologic and Antiseptic Action of Flavine.—Fleming found that flavine has a very destructive action on leukocytes, and if the action on leukocytes and bacteria be each tested for twenty-four hours its leukocidal action is far in excess of its bactericidal action. In serum under certain conditions staphylococci will grow in 1 in 32,000 flavine, *B. coli* in 1 in 1,000, and *B. proteus* in 1 in 2,000. Flavine 1 in 8,000 appears to aid the growth of *B. proteus*. Flavine 1 in 500 is usually unable to sterilize in twenty-four hours an equal volume of pus from a wound. Flavine injected intravenously in large doses immediately disappears from the blood (which acquires no bactericidal power), and is taken up by the tissues, which become yellow but acquire no inhibitory power on the growth of bacteria. Flavine 1 in 100 injected into the pleural or peritoneal cavities loses its antiseptic power within twenty-four hours. If the antiseptic is allowed to act on staphylococci and leukocytes alike for twenty-four hours and the ratio is taken of its toxicity to both of these, phenol has a coefficient ten times better than flavine when the antiseptic acts on the microbes in serum and 250 times better when the bactericidal action is estimated in pus.

18. Method of Applying Antiseptics to Wounds.—The Carrel method, Kellock says, has certain disadvantages. The tubes generally used are perforated with round holes for some distance from the closed end, and if there be much resistance to the exit of fluid at the deepest part the solution finds its way through the openings nearer the surface of the wound and so the deeper parts are not reached. These tubes, too, act to a certain extent as drains. Pus finds its way into them through the openings and is washed back into the wound again when fluid is allowed to flow. Another disadvantage of the method is the necessity of keeping the patient still. Movement on his part is apt to cause the tubes to be drawn out of the wounds, and it is not at all an uncommon experience to find tubes that were originally inserted deeply into a wound lying only just under, or even on, the surface. Attempting to improve on this, Kellock has found the following method of much service. Taking a piece of drainage tube about 8 or 10 inches in length and of caliber about equal to that of a No. 8 catheter, the end is securely closed by a ligature and a small oblique incision made with sharp scissors as near as possible to the closed end. The incision should cut a small valve with apex directed toward the closed end—the more oblique it is the better—and should at its base divide one third of the circumference of the tube. This incision will be found to act as a most efficient valve, opening under very slight pressure from within and preventing any regurgitation of pus or of the irrigated fluid. The tied end should be inserted to the very depth of the wound and the free end of the tube left projecting through the dressings; the number of tubes used must depend on the size and character of the wound, but it will generally be found that one, or at the most two, will suffice. In cases of a perforating wound of a limb or of a wound with two openings widely separated a very useful modification is to ligature the tube at its center and cut a valve on each side of the ligature and pointing toward it. This is passed through the wound and the irrigation done from both ends. In this way any fluid that is irrigated into the free ends of the tube must certainly find its way to the very bottom of the wound and from there toward the surface.

28. **Treatment of Poisoning from Asphyxiating Gases.**—Colard and Spehl combine venesection and oxygen in treatment of the effects of poisonous drift and similar gases. The intoxication is of three types: (1) a brutal and subacute asphyxiated condition from massive intoxication, with intense cyanosis, froth on the lips and vomiting of blood, with rapidly fatal outcome; (2) an acute state of asphyxia developing in those who at first did not seem to be severely intoxicated. The generalization of the bronchitic and fine râles indicates the extent of the pulmonary lesions and explains the asphyxia. The intense cyanosis and changes in the pulse and respiration are characteristic; (3) the third type presents the clinical picture of tracheobronchitis from caustic action, characterized by inflammation of the large and small bronchi and of portions of the lungs, but with enough sound tissue left to maintain the aeration of the blood and ward off asphyxia. Men who have been gassed must be kept under close surveillance, especially during the second week on account of these pathologic changes in the mucosa. Bilancioni produced ulceration in the lungs of gassed animals, and several of the clinical cases here described in detail had a febrile period between the eighth and twelfth days. The clinical picture of the second and third types is much the same at first; then the men in the first group develop asphyxia while those of the second group continue merely their tracheobronchitis. When those of the first group get over their asphyxia, then the clinical picture of the two groups becomes similar once more. In both groups, there is liable to be a febrile period in the second week. The effectual treatment was with venesection and prolonged inhalation of oxygen. Venesection was done at once on every asphyxiated man, fully 300 c.c. of blood being drawn at the bend of the elbow, repeated the next day in the severer cases. The oscillometer shows high blood pressure, but still the blackish blood flows slowly, evidently owing to its exaggerated viscosity. A weak pulse, therefore, in serious intoxication does not contraindicate venesection. It should be done promptly and a large amount of blood withdrawn, from 300 to 500 c.c. according to the condition. The beneficial action from inhalation of oxygen was even more pronounced. The effect depends greatly on the method of administration. The lack of benefit, of which some physicians have complained, is probably due to incorrect technic. Some wait too late and give it to the moribund patient; others give the oxygen too fast, emptying the tank too soon. The proper way is to administer it continuously under a moderate pressure, keeping it up for hours or even days, the patient thus breathing constantly an oxygen atmosphere until the alarming symptoms are past. With this technic, this soon occurs. They give an illustrated description of the arrangement with which they realize these desiderata. The oxygen from the tank passes through tubing into a Wulff jar with three necks, and then through a jar with two necks, a Carrel comb tube and stopcock interposed between the jars. The middle neck of the Wulff jar is connected with a rubber bag to equalize the pressure. The oxygen is introduced through a catheter pushed through the nostril into the rhinopharynx. It is held in place with a string fastened to the brow with a strip of adhesive plaster. As the oxygen is turned on, the bubbling in the two-necked jar shows the rapidity of the flow. It may become stopped by mucus obstructing the catheter in the nose. By this arrangement, oxygen can be administered to more than one patient at a time from the same tank. The passage through the water in the two-necked jar cleans the gas, and moistens it, while the dosage can be regulated for each of the patients separately. The amount found most effectual was from 100 to 150 liters of oxygen for the first hour per individual. When the distress was relieved and the cough and respiratory spasms less violent, the inflow was reduced to about 50 liters an hour. This catheter arrangement does not annoy or incommode the patient like masks and mouthpieces, and he gets the peace and quiet he needs. In a few particularly grave cases they supplemented these measures by giving a little digitalis and strychnin. To ward off secondary infection, especially for those with pulmonary complications, they placed the men in special, well ventilated rooms in which the air was kept constantly humidified with eucalyptol spray. All the other gassed men were in vast barracks with movable sides, kept open night and day. The beds were at least 6 feet apart, and the men were kept in bed for a week at least, even in the apparently mildest cases. Instillation in the nostrils of medicated oil, and inhalation of tincture of benzoin and eucalyptus completed the array of measures to ward off further pulmonary complications, but these are all subsidiary to the main thing, the venesection and oxygen. The value of the treatment is shown in the fact that all the men recovered. The rapidly fatal cases did not live to reach this hospital, Cabour. The Carrel comb-tube referred to has four prongs, and a rubber tube can be fitted to each and thus supply four men with the oxygen at once from the one tank.

29. **Repeated Autovaccination in Treatment of Typhoid and Paratyphoid Carriers.**—Goubau tabulates the findings as to persistence of the bacilli in 431 persons of all ages and both sexes who had been vaccinated once against typhoid and 246 unvaccinated. Of this total 677, 14.33 per cent. still harbored the bacilli after apparent recovery from the typhoid or paratyphoid, but the vaccinated got rid of them sooner than the nonvaccinated, although the difference is not very striking in the table giving the details in sixty-seven cases. None of the vaccinated were carriers of typhoid bacilli beyond the seventh month, while they were found up to the sixteenth month in 0.43 per cent. of the unvaccinated. No carriers of paratyphoid A were found after the fifth month or of B after the seventh. Another group of thirty convalescent carriers were treated with autovaccine or a Wright monovalent vaccine, in weekly injections, and the bacilli disappeared completely in two months in all of the twenty-three thus treated during the first

five months after the disease. The details are tabulated in full of each of the thirty cases, and Gouhau remarks that they apparently establish the efficacy of this autovaccine method of curing carriers. The bacilli disappeared from the convalescents given the vaccine treatment much earlier than in those not thus treated. The effect was prompter the shorter the period after defervescence when the autovaccine was commenced. After an interval of five months no appreciable effect was apparent in 43 per cent. of the cases. When the interval had been only two months, six carriers were cured with three injections; three with four and two others with five and six. The precautions are those for vaccine therapy in general. One case warns to be on the alert for latent tuberculosis as there is a possibility that the repeated vaccine injections may have contributed to the development of frank tuberculosis soon after.

32 *Appendicectomy on Twelve-Hours Old Infant. M. Vargas (Barcelona).—p. 393.
33 *Acute Meningitis in the Newborn. Condat.—p. 404.
34 *Meningo-Encephalitis in the Occipital Region. (Ectopie du cervelet.) E. Kirmisson and Tretiakoff.—p. 412.
35 Obliteration of Inferior Vena Cava in Boy of Twelve. J. Comby.—p. 418.
36 *Hemorrhagic Pleurisy and Sarcoma of the Mediastinum. J. Comby.—p. 423.

32. **Appendicectomy on the New-Born.**—Vargas gives an illustrated description of an infant with a gap in the abdominal wall so that some of the viscera escaped. He was able to reduce the extensive hernia and suture the wall. As the appendix presented under his hand, he resected it as is his practice in such circumstances, and clinically normal conditions were promptly restored. The malformation was of the type of periumbilical cutaneous aplasia. This is the fifth case of the kind he has encountered. The first description of it dates from 1557.

33. **Acute Meningitis in the New-Born.**—Condat relates that three cases of this kind were in the hospital in a recent month. It seems that meningitis is not so rare in the newborn as generally assumed, but it escapes recognition as a rule. Even lumbar puncture may fail to clear up the diagnosis. The symptoms are masked by the general infection of which it is a complication. The streptococcus was found in one case, the pneumococcus in the others.

34. **Meningocele in Young Infant.**—The hernia contained part of the cerebellum in the case described, but this was not suspected before the operation. The base of the tumor was cut away and the pedicle ligated. There were no convulsions or twitchings, and the child seemed to be doing well when it succumbed to an intercurrent violent gastro-enteritis the nineteenth day. The ectopic nervous tissue was evidently a kind of neoplasm, an encephaloma. It included the left lobe of the cerebellum. The right lobe was inside the skull, the cerebellum having evidently twisted sideways.

36. **Hemorrhagic Pleurisy.**—Comby reports two cases of hemorrhagic pleurisy in a girl of 16 and child nearly 3. The particulars of the cases closely resemble two recently published by G. Guidi. They teach that when a pleural effusion is found hemorrhagic, the chances are that malignant disease is already installed in the mediastinum, either in the pleura, lung or anterior mediastinum. In one of Comby's cases the sarcoma had started in the thymus. In all the four cases the onset was similar to that of serofibrinous pleurisy. But soon that half of the chest began to bulge, with exaggerated collateral circulation. Tapping gives only brief relief when the general and local symptoms become aggravated, but the hemorrhagic tint warns of sarcoma.

39 Wounds of the Spleen. J. Fiolle.—p. 170.
40 Modification of Haret-Keating-Hart Method for Localization of Projectiles. A. Badolle.—p. 173.

37. **Case of Anaphylaxis to Quinin and its Cure.**—The young soldier had contracted malaria at Saloniki but was unable to take quinin as it induced vomiting, pruritus, urticaria, colic, dyspnea, distress and lower blood pressure. This tendency to anaphylaxis was overcome by giving him an hour or an hour and a half before the dose an anti-anaphylactic dose of 0.005 gm. quinin sulphate and 0.5 gm. sodium bicarbonate. After this he could take rapidly increasing doses of quinin without any manifestations of anaphylaxis. The case recalls Pagniez' patient whose intolerance for albumin in his food was overcome by his taking a dose of 0.5 gm. peptone one hour before each meal. Quinin, therefore, must now be added to the list of substances which induce anaphylaxis under certain conditions. The case teaches further that in case of drug eruptions and similar disturbances, before renouncing the use of the drug in question it might be well to try this anti-anaphylactic method of a preliminary small amount—the phylactic dose—before the real dose.

38. **Hypnosis in the Field Hospital.**—Podiapolsky writes from Saratov in Russia to call attention to the way in which he has sometimes been able to free the wounded from suffering by hypnotic suggestion that there was no pain or by throwing them into a hypnotic sleep. He describes in detail a number of peculiarly distressing cases in which the immediate relief was most welcome. In war conditions he has found that the men responded with exceptional facility to hypnosis; he found only about 2 per cent. quite refractory. In conclusion he exclaims, "Why give chloroform to subjects who at a word drop off into an artificial deep slumber, which can be counted on in about 17 per cent. of the cases." Even the first degrees of hypnosis permit operations with much less of the general anesthetic than would otherwise be necessary. He has found it useful for the wounded of all the nationalities that he has encountered, Slavs, Teutons and Italians. He does not advise the hypnosis for major operations but mainly for the sensory crises of psychic origin, such as the pain felt apparently in a limb after it has been amputated. A single hypnotic sitting may cure completely distressing pains of this nature. Podiapolsky's polyglot environment caused trouble sometimes, as he did not always know the word for "wake up" in the patient's own tongue. Now he makes sure of this before attempting the hypnosis.

41. **Elimination of Quinin by the Urine.**—The tabulated findings show that quinin has to be administered daily to keep the patient under its continuous influence, by whatever route it is given with the exception of the intramuscular. With this route, administration every second day suffices.

42. **Diphtheria.**—Danysz presents theoretical data testifying to the fundamental difference between the evolution of diphtheria and of the majority of other infectious diseases. It seems to be a local infectious disease caused by a colloidal, soluble, directly toxic antigen with a special affinity for tissues of ectodermic origin. There is no incubation. The normal intracellular antibody can fasten the antigen and form compounds with it. The resulting intracellular reactions are immunizing if the quantities of antigen and of antibodies balance each other. They become pathogenic when the antigen is in excess. The intravascular reactions consist in neutral compounds soluble and able to be directly assimilated or eliminated if the antigen and antibodies (antitoxin)

balance each other, or if the latter are in excess. Diphtheria never induces anaphylactic hypersusceptibility.

43. **The Oculocardiac Reflex in the Wounded.**—Gautrelet emphasizes the peculiar intensity and constancy of the oculocardiac reflex in most of the wounded when the test is applied several months later. It is exceptionally intense in the men with reflex contracture. The only exceptions are the cases of exclusively bone injuries. These findings suggest that the nervous system is unbalanced, the autonomic nervous system gaining in influence.

45. **Contracture of the Fingers.**—Claude and Dumas give an illustrated description of the various types of claw-fingers that develop after the different types of injury of the nerves in the arm. They must not be regarded as inevitable or necessarily permanent, but should be warded off or overcome by massage of the muscular masses of the forearm, especially of the flexor group, the massage repeated twice a day, at least, under the directions of the neurologist and surgeon. Each finger should be mobilized separately, to the extreme extension possible, repeating this several times a day. In addition to these passive exercises, which will aid in overcoming a tendency to stiff joints, these measures are supplemented by regular immobilization of the fingers in hyperextension on a board, at night only, unless retraction is menacing, in which case the hyperextension immobilization should be kept up the greater part of the day as well as at night. When these measures are applied systematically and efficiently from the first, he says, that day will witness the disappearance of claw-fingers in all cases except with absolutely irremediable section of the nerve.

46. **Heart Disease on the Firing Line.**—Aubertin states that during the three years of the war the men with heart disease have been gradually sifted out and sent back to him as chief of a service for heart disease. Many with mild functional disturbances promptly recuperated and returned to their post at the front. Those with organic trouble have been apportioned to light duty or dismissed from the ranks altogether. In a recent series of "cardiacs" thus received at his service, 9 per cent. were sound and had merely managed to convince the army doctor that something was wrong with their heart. In 12 per cent. the heart symptoms were traceable to incipient tuberculosis, alcoholism, anemia in the young and fatigue in the older men, without actual heart disease. With actual organic trouble he found only two cases of thyroid origin among the thirty-two men with tachycardia and one case of paroxysmal tachycardia. Extrasystolic arrhythmia is generally labeled myocarditis, although his examination always failed to disclose anything abnormal in the functioning of the heart. This type of arrhythmia, he remarks, frightens the unwarned physician more than it frightens the patient. In short, he declares in conclusion, there still are some men at the front with organic heart disease, but nearly all have some slight aortic systolic murmur which escapes detection except at times of unusual physical stress, at which time attacks of tachycardia develop. The soldiers with valvular disease have nearly all been sifted out by this time.

47. **Radiotherapy for Wounds of Nerves.**—Bordier and Gérard report twenty-five cases to confirm the great benefit liable to follow exposures to the Roentgen rays after war injury of nerves. The response to electric stimulation returns to normal when the exposures are given early. They advise surgical intervention when the reaction of degeneration is complete. Then radiotherapy applied at once may promptly restore normal conditions. They are hopeful that it may be possible by this means to ward off paralysis and other infirmities consecutive to severe injury of nerves. But to accomplish this, the men with one or more nerves which fail to respond to electric stimulation must be kept in the hospital long enough for the different measures applied to realize their full and complete therapeutic effect.

Progrès Médical, Paris

August 11, XXXII, No. 32, pp. 265-272

51 *Reaction to Pinching of Muscle over Pleuropulmonary Tuberculous Lesion. (La réaction myotonique du trapèze dans la tuberculose pleuropulmonaire.) M. Loeper and H. Codet.—p. 265.
52 *Simple Contusion of the Knee. A. Chalier.—p. 266.
53 Symptoms with Lesions of the Cauda Equina. J. Lhermitte.—p. 267.
54 *Occupational Training of War Cripples. A. Marie and A. Rodiet.—p. 269.

51. **Reaction to Pinching of Muscle Over Tuberculous Pleuropulmonary Lesion.**—Loeper prefers to call this the myotonic reaction, as elicited by pinching the trapezius. Whatever the response, it is normally alike on both sides, and when it is exaggerated on one side only it points to irritation of the muscle fibers from some cause. In his experience with 300 tuberculous patients examined, the myotonic reaction was more accentuated on the side of the active pleuropulmonary lesion. Congestion of the apex was always accompanied by exaggeration of the reflex, while it was always reduced with pleurisy without effusion. Of course sclerous lesions and other torpid trouble are not accompanied by the myotonic reaction, but it may be found an aid in locating a pulmonary lesion, in estimating its depth beneath the surface, and whether it is active or not.

52. **Contusion of the Knee.**—Chalier calls attention to two mistakes constantly made by army surgeons, the undue clinical importance attributed to simple slight hydrarthrosis, and the inadequate treatment given sprain and hemarthrosis. The latter requires immediate and absolute immobilization in bed for several days, with a cotton compressing dressing. If the effusion persists or increases, by the fourth or fifth day it should be evacuated by puncture and the knee should be immobilized in plaster. One puncture is generally enough, and massage should be applied, still keeping the man in bed, with automassage, active contraction of the quadriceps, raising and lowering the leg. By the eighth or tenth day the man can be allowed to walk a little, the knee still in the plaster ring until the fifteenth day. After this the knee can be gradually used, and the man is ready to resume his active service in about six weeks from his trauma.

54. **Occupational Training of War Cripples.**—Marie and Rodiet discuss a bill that has passed the lower house and is now before the French senate. It is based on the two principles of the obligation to ensure professional reeducation of the wounded and mutilated soldiers, and that this should not encroach on their pension. By ensuring assistance to all disabled soldiers who are yet capable of steady occupation, the law thus provides for the most numerous category of the mutilated. It does not apply, however, to the severely crippled or to those incapable of sustained wage-earning occupation who will find their place in the soldiers' homes, and those unable to benefit sufficiently by training after it has been given a thorough trial. Marie and Rodiet urge that the present bill should be amplified to include special provision for the "mentally disabled," the neurasthenic, the depressed, the confused, and those disabled by derangement of the nerve centers. Most of them have a home and a family to return to. But those who have no home, what is to become of them? Some provision should be made for them instead of keeping them on indefinitely in the hospitals. Their suggestion is that the nervously and mentally disabled of this type should be boarded out in families in country districts. This method of assistance offers a more cheerful and a saner life than hospital existence in towns. It conforms better to the aspirations of the individual and to mental and physical hygiene. It also spares the public funds the enormous expense of hospital care for so many with grave chronic affections and those disabled beyond steady wage-earning capacity. This plan of boarding out in the country the chronic invalids was proposed before the war by P. Fleurot to relieve the overcrowded Paris hospitals.

This method of boarding invalids out in country families has long proved its usefulness in the other countries of Europe, and in France it has been successfully applied since 1892 for a large number of the chronic insane who are not getting any further benefit from hospital treatment. The board in charge of the war cripples, provided for in the bill, could assemble these mentally disabled in certain villages or small towns, letting them choose the family with which they wish to make their home. The board paid must not encroach on the man's pension. These disabled might be capable of some light work, possibly home work. Bergonié has recently reported astonishingly fine results obtained in the correction of motor sequels of war wounds by graduated farm labor. The authorities in consequence are already organizing small agricultural sanatoriums in connection with the institutes for physiotherapy. By extending this system, the mentally and nervously disabled would find homes and excellent conditions for restoration to normal.

59. **Iodin Urine Reaction.**—Thury reports that the findings with Petzetakis' urine iodin reaction were so contradictory in her experience that it does not seem to have any value for either diagnosis or prognosis.

62. **Operations for Hernia in Children.**—Brossy here presents the findings nine years or more after an operation for hernia on 287 children. He states that nine died soon after the operation among the 642 children treated for hernia since 1888, but death in one instance was of the thymus-death variety and in another was the result of iodoform intoxication. Children liable to thymus death should not have any operation done that can possibly be deferred. In four other cases the children succumbed to infection probably acquired in the hospital. These cases show that the sojourn in the hospital is liable to entail grave consequences, and hence an operation should not be advised lightly for children; not without absolute necessity or special quarters, with one or at most two beds in the room, and no visitors allowed. The other three deaths had probably no connection with the operation. Among the 287 with an interval of at least nine years since the operation, seventeen have died during this period, including nine that were under 2 years old at the time. Two years seems to be the lowest safe limit for these operations. The article is to be continued.

63. **Indicanemia as Symptom of Renal Insufficiency.**—Tchertkoff expatiates on the importance of indican in the blood as a sign of grave incompetency on the part of the kidneys. The technic he describes for estimation of the indicanemia reveals it only when it is within a pathologic range: to 8 or 10 c.c. of serum (obtained fasting by wet cupping or puncture of a vein), he adds an equal quantity of 20 per cent. trichloracetic acid, and filters. Then, to 10 c.c. of the filtrate he adds an equal quantity of concentrated hydrochloric acid containing 5 gm. of ferric chlorid to the liter. The whole is agitated, and then 3 c.c. of chloroform is added. After having agitated it several times in the course of fifteen minutes, he examines for the color reaction. The chloroform changes to a light or dark blue according to the proportion of indican in the serum. If there is no indican, the chloroform has no color. If there is iodin in the serum, the chloroform turns pink or a pinkish violet. This technic is reliable also for detection of iodin in the serum, but as this may interfere with the indican reaction, no iodin should be given the patient before the test. In his examination of 300 serums, indicanemia was invariably found when the azotemia reached nearly 1.5 gm. to the liter, but it sometimes disappeared before the latter—a favorable sign. It persists to the end in the fatal cases. Experimental research confirmed these clinical findings. There may be indicanemia with slight uremia; but the prognosis should be based on the persistence of the former. He thinks there is no need for quantitative estimation of the indican; the fact that it is within pathologic range is enough. The range shown by the technic described is about 2.5 mg. Any amounts above this show merely that the production of indican is large; they reveal nothing beyond the fact of renal incompetency already shown by the 2.5 mg. As the kidneys fail to allow the passage of any of the substances produced in or introduced into the organism, he remarks that "uremia" or even "urinemia" is a better term than "azotemia." Whatever we term it, the condition calls for a diet which can be oxidized without waste, little albuminoids and little salts, while the caloric demands should be reduced to the minimum. Indicanemia with chronic nephritis indicates a fatal outcome in a few months or weeks.

64. **Hematuria with Phosphaturia.**—In the four cases reported by Perrier there was slight but frequent hematuria, sometimes almost continuous, with periods of exacerbation, either spontaneous or following pain in the kidney or fatigue. The general health was not impaired and micturition was normal. The urine, however, constantly contained a mineral sediment, phosphates alone or associated with urates and uric acid. There was no tendency to hemophilia, tuberculosis, lithiasis or tumors. The patients were two young men, a woman of 26 and a man of 38. He prescribed hydrochloric acid and in the one case in which his directions were followed, the urine became limpid and there have been no further disturbances. The phosphaturia is unmistakably a factor, but probably the kidneys are exceptionally sensitive.

Correspondenz-Blatt für Schweizer Aerzte, Basel

August 18, XLVII, No. 33, pp. 1057-1088

66 *Clinical Study of Cerebellar Cysts. M. Düring.—p. 1057.
67 * Experiences with Vaccination against Typhoid. F. Oeri.—p. 1067.
68 Medical Certificates and the Honorarium. (Zum Krankenschein-Wesen.) C. Bührer.—p. 1072.

66. **Cyst in the Cerebellum.**—Düring's patient was a woman of 32, with three healthy children. She had been healthy except complaining of pains in the back of the neck since childhood. During the last four or five months there had been much headache, dizziness and vomiting and a brain tumor was suspected in the left cerebellum. The woman succumbed to respiratory paralysis while being prepared for the operation at the fifth month. A cyst as large as an egg was found in the left cerebellum, with a small glioma projecting into it, relics of a larger tumor, possibly. He discusses the symptoms in this case, particularly those for which the disturbance in the adjoining pons and oblongata were responsible. These remote deficit symptoms are particularly important for differentiation of intracranial tumors. The total paralysis of the left vestibular nerve was accompanied by total left facial paralysis, but the fact that the hypoglossal escaped excluded hemiplegia from a focus in the frontal lobe or anterior segment of the internal capsule. The data of this case sustain the assumption that paresis of the extremities has a cerebellar basis. Sensory disturbances are rare with tumors in the posterior cranial fossa. Puncture of the brain seems to be the only safe means to differentiate between cysts and tumors. It has given good therapeutic results, also, in the hands of some. Palliative puncture of the ventricle may be indicated in certain cases, Düring adds, puncturing at the point where pressure is highest. He calls attention further to the very high pressure noted in the ventricle on the opposite side in his case. Internal hydrocephalus is largely occipital as there is less white substance here to interfere. The occipital lobe stands puncture well.

71. **Circumscribed Goose-Flesh or Trichographism.**—Pende calls attention to a form of dermographism which indicates hyperexcitability on the part of the sympathetic nervous system. Like the white or red line of ordinary dermographism it is induced by marking on the skin with a blunt point, a line of goose-flesh minute papules following the mark. He has coined the terms trichotony and trichographism to express this induced localized contraction of the arrectores pilorum, a circumscribed localized cutis anserina or goose-flesh.

77 *Residual Chronic Suprarenal Insufficiency Left After Epidemic Jaundice. G. A. Notari. Commenced in No. 31, p. 309.

77. **Chronic Suprarenal Insufficiency after Epidemic Jaundice.**—Notari describes six new cases of this type, giving the findings in detail from day to day. The pigmentation resembled that of Addison's disease and the weakness was extreme; in one case there were two periods of acute suprarenal insufficiency. The exaggerated oculocardiac reflex and the organic reactions to atropin and pilocarpin show that in these cases the sympathetic hypotony seems to be compensated for by the hypertony of the autonomic system. It seems to be evident that next to the liver and kidneys the suprarenals suffer most from the spirochete infection. The spirochetes accumulate in them in enormous numbers. In the cases described the blood pressure was not abnormally low or but very little below normal and epinephrin depressed instead of raising it or did not modify it at all, or only slightly. There was no epinephrin glycosuria. The data reviewed confirm, he says, Monti's statement that besides the direct action of the spirochetes on the suprarenals, they suffer additionally, indirectly, from the alterations observed at necropsy in such cases in the solar plexus.

80. **Retention of Bile.**—Segura reports eight cases to show the difficulty of differentiation in certain cases of jaundice. They emphasize that surgical treatment is imperative when jaundice has lasted for two months at farthest. The laparotomy may reveal a benign curable process when everything seems to indicate malignant disease. The retention of bile injures the liver and is liable to induce a hemorrhagic diathesis. This proved fatal in two of the cases reported in which the operation came too late, the whole trouble being merely from an echinococcus cyst in the liver. In another case the liver opened into the bile passages, and there was transient obstruction at intervals, probably from expulsion of daughter cysts. As these were finally passed along, the obstruction was only temporary and there was no tendency to hemorrhages. Even when the laparotomy discloses malignant disease, gastro-enterostomy may permit long survival as the retention of bile otherwise is liable to prove fatal before the patient succumbs to the cachexia. One of his patients was a man of 23 with primary cancer of the biliary passages, inoperable when first seen. There was no history or trace of gallstones in this case. Necropsy in the case of a man of 58 showed cancer developed in a duodenal ulcer. The ulcer symptoms had been unmistakable for two or three months and then jaundice developed within a few days, evidently from invasion of the bile duct by the carcinoma. In another case a hard drinker developed suddenly pain in the liver, and jaundice, but in the course of six weeks of rest and careful dieting the jaundice had almost disappeared and the man of 60 had gained several pounds in weight. Catarrhal jaundice was the diagnosis, but the jaundice grew more intense by the end of three weeks, with subcutaneous extravasations of blood and ascites. Necropsy revealed a primary nodular cancer in the liver. In a case of Hanot's cirrhosis of the liver there was no jaundice or fever for a year and a half, but then jaundice gradually developed with intense pruritus and a loss of over 40 pounds in weight. The stools were absolutely clay colored, and a passage for the bile was made by joining the gallbladder and duodenum. The patient succumbed to pneumonia not long after. Another man of 33, with drinking habits had long had frequent digestive disturbances, ascribed to the stomach, when a very severe attack of indigestion followed eating five melons. The bowels did not move, even under repeated doses of castor oil, and the fifteenth day jaundice developed. The liver could be palpated at the fifth rib but it was not tender through the interspaces; the lower margin was slightly tender. He improved in the hospital, gaining over 11 pounds in weight in two months and returned to work, but the liver increased in size and ascites required tapping. The diagnosis wavered between four different liver diseases after the assumption of catarrhal jaundice had been dropped, but necropsy, eighteen months after the first sign of jaundice, disclosed cancer of the ampulla of Vater.

87. **Tumors in the Bladder.**—The title of Fedoroff's article is "My Views on the Modern Treatment of Tumors in the Bladder," as he is convinced that when there is a suspicion of malignant disease or the tumors are multiple or are located in what he calls the neck of the bladder, the usual treatment does not guarantee against recurrence. His experience with 165 operative cases of bladder tumor and review of the literature have shown that a single tumor can be removed by an intravesical intervention without fear of recurrence. But recurrence is the rule after an intravesical operation for multiple tumors or cancer. He knows of only one case on record (Pawlik) of survival for fourteen years without recurrence. In his own series, 20 per cent. of the 165 patients have had no recurrence during the two and a half to thirteen years since operative treatment, and nothing is known of the ultimate outcome of 50 per cent. The remaining 30 per cent. had recurrence of the tumor within two years except in two cases in which the interval was three years and one in which it was five. Fedoroff presents further arguments to prove the necessity for extending the indications for removing the bladder and transplanting the ureters at an early stage of malignant disease and with multiple tumors. The otherwise

doomed patients are thus restored to comparative clinical health and their sufferings are terminated at one stroke. He reports a few cases in detail to show the value of this dual intervention. One physician of 39 had had occasional hematuria since the age of 17, and three suprapubic operations and one intravesical had been done to clear the bladder of recurring multiple papillomas in turn by Guyon, Nitze, Casper and Bazy. Pains and tenesmus were finally almost continuous, requiring up to 0.4 gm. morphin daily, and a suprapubic fistula into the bladder complicated matters. Then, in March, 1911, Fedoroff transplanted both ureters into the lower sigmoid flexure, and, in April, shelled out the bladder with part of the prostate. The relief from pain after the transplanting of the ureters was like magic. In June the physician was able to resume his practice as if raised from the dead. When the bladder was removed the microscope showed traces of cancer in the tumor but it had not invaded the walls of the bladder or lymphatics. The bladder seems to be peculiar in this respect. But still, two and a half years later, other papillomas and a cyst developed in the small pelvis. Evidently the pelvis had been inoculated with tumor cells during the removal of the fistulous bladder. Another serious feature of the case is that the otherwise fairly healthy man has had several attacks of pyelitis during the last five years although he has been able to keep up his practice and has felt well otherwise. Fedoroff remarks that we must not forget that the kidneys in such cases must be already suffering from obstruction of the outlets by pressure from the tumors.

92. **History of Modern Hospital in Holland, Founded in 1308.**—Schoute has compiled from the archives of the hospital at Middelburg and from other local sources a valuable contribution to the history of medicine in the fourteenth century and during the centuries since. A number of illustrations show the ancient building and its administrators. The actual founder is not known, but a deed showing a bequest to the hospital from a widow is on record, dated 1308. The hospital archives were kept with minute record of details, and the financial ups and downs of the hospital reflect the political events of the various centuries. The directions for greater economy in administration at various periods are interesting. During the first centuries of its existence the archives show that the hospital combined the functions of an asylum for the aged, for foundlings and orphans, an inn for transients, charity work in general, and church, school and political headquarters, in addition to its regular hospital work. The very name for hospital in the Netherlands language, *Gasthuis*, "guest house," suggests its original manifold uses. The earliest picture of St. Barbara's dates from 1696. It required a very active and energetic campaign by two local physicians, preaching the necessity for ventilation, pure water, etc., to bring about the destruction of the antiquated building. Their pamphlet published in 1857 preaching modern hygiene told, among other records, of their own school days in the old building, the dark rooms, the ink freezing. Their campaign was reenforced by a smallpox epidemic spreading from the hospital, and the old building was demolished in 1866, but its records were preserved and the *Leggerboeks* dating from 1604 and 1687, with the rules and regulations for the administration of the hospital.

93. **Chronic Headache as a Manifestation of Asthenopia.**—Van der Brugh remarks that so many factors are liable to bring on headache, that no one physician is able to master all the specialist methods of investigation of its etiology. He devotes this communication to the habitual headache resulting from disturbance in the motor apparatus of the eyes, especially a loss of balance between the external eye muscles. He has had seventy-one cases of the kind in less than three years, and has completely cured fifty-eight with prisms. The general practitioner, the laryngologist, rhinologist and otologist, who are the ones generally consulted on account of chronic headache, can differentiate it as a case of heterophoria by bandaging one of the patient's eyes and letting him go around otherwise as usual. If the headache improves in the course of a few days under the use of the bandage; then some loss of balance is the cause of it, in all probability, and this can be readily corrected with prisms. There is a special group of sufferers in this class, he says, those who come home from the theater, lecture, concert or church with a raging headache. He has found esophoria in all such cases and with the aid of correcting prisms the tendency to headache disappeared. He describes the other types of heterophoria, and warns that girls and young women do not like to wear glasses, but when they discard their prisms the headache returns. Still more convincing is the experience that those with hypermetropia, besides the esophoria, still have their headache persist when glasses to correct the former, but not the latter, are fitted. Not until they are supplied with prisms do they lose their headaches. A special characteristic of headache from esophoria and hyperphoria is that the tendency to headache subsides in the dark and at night. Such patients usually relate that they have had the headaches a long time and have been treated for them by the family physician for weeks, months or years, without relief. They have been repeatedly examined by nerve and nose specialists but no cause for the headache could be found. They finally gave up hope and resigned themselves to their suffering, so that the prompt and complete cure when fitted with proper glasses is an overwhelming surprise. The loss of balance to which he refers used to be called latent strabismus, but time has shown that this term is incorrect. He describes a typical case in a boy of 7, showing the cure of the headache after he had been fitted with prisms, its return when he broke his glasses, and its banishing anew with the repaired glasses, while the general health improved remarkably when relieved from the depressing headaches.

96. ***Heart Block with Epilepsy.***—The elderly man in question had had complete heart block for the last five years. From his thirtieth year he had attacks resembling epileptic seizures. They began with suspension of heart action and respiration. In the attacks while under observation, the pulse stopped abruptly for 105 seconds and possibly longer, while the respiration was suspended for two and three-quarters minutes. Kouwenaar discusses whether this combination of epileptic seizures and heart block is casual or there is some causal relation between them. The convulsions were bilateral, symmetrical tonic-clonic cramps with episthotonus. They bore a suggestion of Hughlings Jackson's "cerebellar attitude." This is instructive, in connection with the bulbar theory of the causes of convulsions in persons with heart block as *claudicatio intermittens* of the bulbar vessels.

RECENT BIOCHEMICAL INVESTIGATIONS ON BLOOD AND URINE

THEIR BEARING ON CLINICAL AND EXPERIMENTAL MEDICINE *

OTTO FOLIN, PH.D., S.D.
Professor of Biologic Chemistry, Medical School of Harvard University
BOSTON

It is generally recognized that progress in the development of any experimental science is more often due to the discovery of new methods than to new and more ingenious applications of old ones.

An unending procession of new remedies and new procedures moves across the field of clinical medicine. The wide attention bestowed on Abderhalden's pregnancy test may be cited as a specific illustration of the eagerness with which the medical profession is waiting for new methods. Brugsch's new nitric acid test for syphilis is another illustration. This test will doubtless prove even more alluring to those who have opportunity to try it; for, whereas the Abderhalden test was complicated and admittedly full of pitfalls, this new test for syphilis seems almost ideal in its simplicity. Its lack of "rhyme or reason" will not deter many from trying it.

In the science of biochemistry, too, we have had a constant succession of new methods, and a very important phase of the biochemical research of today is still the development of analytic technic. In the last few years there have been very great changes in the methods used for the analysis of urine, while the advancement in the field of blood analysis has been ever more remarkable.

The foremost characteristic of the successful modern analytic method is speed. With reference to the value of time, the biochemical investigator of today is no less keen than are the leaders in modern industry. Many of the older methods in use, say fifteen years ago, as, for example, Salkowski's method for uric acid, the Mörner-Sjöquist method for urea, or the Schlösing method for ammonia, were accurate enough, but they were slow, and they did not encourage the application of chemical methods to the study of clinical problems. When a physician had to wait four days before he could learn how much ammonia a given urine contained, he did not bother himself very often about determinations of ammonia. And, as a matter of fact, this good old method for the determination of ammonia was so little used that investigators gradually forgot how the method must be employed in order to yield correct results.

Today any analytic method in urine analysis which cannot be finished within less than two hours stands in need of further revision. Most of the common determinations in urine and blood will become from fifteen to thirty minute methods for single determinations, and also several determinations will be made with little extra expenditure of time.

Almost every material reduction in the time and labor required for a given determination is followed by an increase in the number of investigators who make researches based on that determination. But it is only when we come down to the very shortest of biochemical methods that they begin to appeal to clinicians, and it is, I think, no small triumph for the modern technic that clinicians have begun to compete with laboratory specialists in the fields of research suggested by these new methods.

A considerable and constantly growing number of American physicians now possess laboratories in which chemical determinations are made. It is difficult as yet to appraise the probable value of this kind of work contributed by clinicians. A large proportion are busy practitioners who have considered their own time too valuable to permit them to acquire any personal mastery over the methods. Hence they hire technicians to do the work without themselves being competent to judge of the quality of the work. The net gain to science from such work must be distinctly problematic.

There is a legitimate and important use for technical assistants in the innumerable little laboratories springing up in connection with private and with hospital practice of medicine, but it seems to me extremely important that this use should conform to some reasonably honest standard of responsibility. The physician should know at least as well as his technician each and every kind of determination that the technician makes for him. Every method goes wrong now and then, and the physician who is as helpless as is the technician when something does seem to be wrong has but meager qualification for the work he is trying to do.

The current misuse of technicians does impair somewhat the credibility of laboratory observations recorded by clinicians, but this represents presumably only a passing phase, and it does not obscure the fact that many clinicians are keen and alert for every new chemical method which is sufficiently practical for their needs. It is unfortunate that the laboratory expert and the competent clinician cannot be united in one person. It is unfortunate that methods must be simple and easy, as well as quick, before they can find any very widespread and sound application within the medical profession. The modern methods are wonders in quickness in comparison with the old ones, and

---

* Third Mellon Lecture under the auspices of the Society for Biological Research, University of Pittsburgh, May 18, 1917.

they are not very complicated; but no man knows them who does not know how to check up his own results by working against theoretical figures.

A second characteristic of modern analytic technic, as distinguished from the old, is the tendency to make the methods microchemical. Formerly a full twenty-four hour quantity of urine was scarcely large enough to permit a complete analysis. Today 10 c.c. of urine is abundant for a determination of all the more common nitrogenous constituents. We still demand twenty-four hour samples of urine, and have gone on the assumption that we must have them to secure a satisfactory picture of the waste products; but we do not need them for the analyses. Indeed, many modern researches are based on analyses of urine representing periods much shorter than twenty-four hours.

The importance of being able to make quantitative studies on the basis of less than twenty-four hour urines is shown in the recent communications by Dr. Denis on creatin. We still do not know for certain some things which we must find out about the origin of this product. We know that the muscles contain creatin, or its precursor, and that in the urine we find normally (except in children) a great deal of creatinin, but only traces of creatin. It now turns out that these traces are not excreted, as is creatinin, at a substantially uniform rate from hour to hour. On the contrary, the creatin excretion is confined to a short period after each meal.

The time honored twenty-four hour system of urine analysis has been and will remain important; indeed, it will remain indispensable in some kinds of metabolism work. The twenty-four hour system is, nevertheless, largely a relic of what might be called the nitrogen equilibrium period in the history of the science of nutrition. But nitrogen equilibrium has largely ceased to be a factor to which we must pay attention in metabolism studies on human beings. For we know perfectly well that it is only by means of carefully selected diets that we can give a person enough food to meet his energy requirements without at the same time giving him enough protein for the maintenance of a normal level of nitrogen equilibrium. We may often enough wish to determine the general level of nitrogen elimination, but it is rare indeed that we need to know or actually do determine any little discrepancy that may occur between the intake and the outgo of nitrogen. Nor can such discrepancies be determined except on the basis of experiments a great deal longer than one twenty-four hour period. Twenty-four hour urines are no longer needed even for very comprehensive analyses, and I am convinced that for many purposes, and particularly for clinical studies, we shall find that urine analysis based on definite three hour, or at most four hour periods of urine collection, will yield considerable new information and will greatly simplify the application of quantitative methods to the study of metabolism problems. The change will increase enormously the possibilities for doing quantitative metabolism work on patients, very few of whom can be relied on to collect twenty-four hour urines. The use of standard three hour urines will reduce to a minimum the extent to which the work can be ruined by carelessness or incompetence on the part of nurses; in fact, the nurse's part of the work will be almost eliminated. Private patients, even office patients, and outpatients in the hospitals, can be included in our metabolism investigations if we once get our metabolism period reduced from twenty-four hours to three hours.

For such work we shall need a large series of normal figures corresponding to the twenty-four hour figures which have been used in the past. I hope shortly to furnish such figures for the first three hour morning period and for a second period representing the effect of a standard test meal.

The practical advantages to urine analysis derived from the speedy microchemical colorimetric methods are less fundamental than are the advantages gained from the application of the same principles to the analysis of blood. Before the introduction of these methods one could hardly say that there was such a thing as quantitative blood analysis. There were no definitely recognized methods, and in the scattered analyses attempted each investigator usually improvised some sort of procedure according to his own light and without reference to any general need for some system of blood analysis. For a qualitative test for uric acid in blood, from 100 to 200 c.c. were required, and even then positive results were obtained only with blood abnormally rich in uric acid. Today we can make quantitative uric acid determinations on any kind of human blood, and do not need more than 10 c.c. for the determination. If necessary we can make the determination with 5 c.c. or less.

The merit of the newer microchemical system of blood analysis was convincingly demonstrated in connection with studies on the problem of protein absorption. For more than a generation different investigators had tried over and over again to demonstrate the nitrogenous digestion products in the blood stream, but had failed, and we had nothing but unproved hypotheses with which to explain the absorption of albuminous food. This problem became acute when it was shown by Kutscher, at the beginning of the present century, that the pancreatic digestion is capable of completely destroying the protein character of albuminous materials. The earlier investigators worked with anywhere from 100 c.c. up to several liters of blood in attempts to solve this problem, and failed. Working with from 2 to 5 c.c. of blood by the micromethods, it was shown with absolute certainty that the old hypotheses were false, that the simple digestion products elucidated by Kutscher were readily and rapidly absorbed. The products could be traced through different parts of the circulation and even into the various tissues of the body.

The methods were equally applicable to the determination of the waste products produced within the tissues. In studying these phenomena, the results obtained were as clear as if we had actually seen the digestion products (the amino-acids) pass into the blood and into the tissues, there to linger awhile, and finally break down and yield urea. To any one who has actually followed this process, as Dr. Denis and I followed it in cats, there can be no doubt as to the essential features of protein metabolism, and the ability of muscular tissues to form urea. Nor can there be any doubt about the important fact that metabolism products pass with great speed and readiness from the blood into the tissues, and vice versa. There is every reason to believe that when we determine the urea content of the blood we are at the same time determining approximately the urea concentration of the muscles.

The speed with which a condition of approximate equilibrium is established between the blood and the tissues in the case of ordinary soluble products has never received the consideration and study that this phenomenon deserves. The literature abounds in explanations of clinical or metabolism problems based on the assumption that the blood is almost a closed system with reference to the general tissues of the body. I doubt not but that there is such a thing as selective affinity between this or that product and this or that tissue. There must be some specific cause, however, for every case of such selective accumulation, for each case must be regarded as more or less of an exception to a general rule.

As an interesting erroneous explanation of an important metabolism problem based on a misconception as to the equilibrium phenomenon between the blood and the tissues may be mentioned the old hypothesis that creatin is the intermediate product in the breakdown of body protein into urea.

The muscles are relatively loaded with this simple crystallizable product, creatin, and it was indeed plausible to assume that this highly nitrogenous extractive, a hundred times as abundant in the muscles as in the blood, must be the connecting link between the broken down tissue protein and the urea. Feeding experiments with creatin did not yield urea; but to this Bunge retorted that creatin, when fed as such, does not have time to get into the tissues and is eliminated before there has been a chance to accomplish the conversion into urea. Both the original hypothesis and Bunge's auxiliary hypothesis advanced in its defense are thus clearly seen to assume the absence of the equilibrium phenomenon referred to. The fallacy in Bunge's argument has never been pointed out so far as I know, and it was not until three or four years ago that it was shown by microchemical analysis that Bunge's argument was false; that, in point of fact, creatin is readily absorbed from the blood by the tissues.

While the view that creatin is the chief precursor of urea was long ago abandoned, many still believe that a part of the urea is so produced. The important point, however, is that creatin is not to be regarded as essentially a precursor of urea, and that we accordingly must find some other explanation of why the muscles contain such large amounts of creatin. This is a problem of normal metabolsim rather than of clinical or experimental medicine. Whether out of it will grow any clinical problems we cannot yet tell. Human beings do not lend themselves to tissue analysis.

Before I go any further it is perhaps well that I should indicate a little more definitely the character and scope of the microchemical methods already in use for the analysis of blood. We have then, first of all, the colorimetric methods for the determination of each of the chief nitrogenous substances found in urine, that is to say, the total nonprotein nitrogen, the urea, the ammonia, the uric acid, the creatin and the creatinin. In addition we have Bloor's micromethods for the lipoids-fat, lecithin, and cholesterol; Marriott's nephelometric methods for the acetone bodies; Benedict's method for the blood sugar, and finally Lyman's very recent method for calcium. The remarkable thing about this series of methods is that they are devised with reference to a single instrument, the colorimeter, which can also be used as a nephelometer. With the combined instrument we simply measure the amount of color which the substance to be determined can be made to give with some suitable reagent, or we measure the cloudiness, if the characteristic reaction used results in a precipitation instead of a color. In principle these methods are somewhat similar to the clinical method of determining the hemoglobin in blood. In the analytic methods of earlier times the investigators proceeded on the principle that the amount of material taken for each analysis must be inversely proportional to its concentration of the substance to be determined, and this principle, for obvious reasons, virtually excluded human blood or blood from small laboratory animals. In the microchemical system of analysis, on the other hand, the guiding principle is to overcome the lack of concentration and the limited supply of blood by the application of correspondingly intense and sensitive reactions. The amount of blood used for each determination in the series mentioned above varies from a fraction of 1 c.c. up to 10 c.c. To be strictly practical, a blood method must not require more than 10 c.c. of blood, and its value is greatly increased if it can be applied to 5 c.c. or less. On the other hand, when one attempts to work with too insignificant quantities, that is, with drops of blood, the technic again ceases to be practical, because this can be done only by a complicated system of weighing instead of measuring the blood taken. This modern system of blood analysis has all been developed within the past six or seven years, and it is still not complete.

I have made no reference to other recent useful analytic procedures, such as Van Slyke's methods for amino-acid nitrogen and for chlorids.

We are still in the early stages of a pioneer period of research opened by means of all this new technic, but it is clear that much research lies ahead of us with reference both to physiologic and to clinical problems. As yet there is not always sufficient agreement as to the values which should be accepted as strictly normal. Take the nonprotein nitrogen and urea, for example. There is no doubt, I think, that in case of strictly normal persons such as we find among medical students (or outside of hospitals), the nonprotein nitrogen content and urea content of blood are low. The nonprotein nitrogen will not exceed 28, or at the most 30 mg. per hundred c.c. of blood, and the urea nitrogen will be almost exactly one half of the nonprotein nitrogen. Nor are these levels materially affected by reasonable variations in the nitrogen content of the food. To me it seems a matter of considerable significance that we have to accept as normal considerably higher levels just as soon as we begin to work on hospital patients. Here values lying between 30 and 40 are quite as common as values under 30. There can be no doubt about the fact that efficiency of the kidneys is the chief factor which determines the level of waste products which any individual carries in his blood and tissues. The higher levels of waste products found among hospital patients must therefore indicate that at least one half of these persons have kidneys which are no longer perfect, kidneys which at one time or another and in one way or another have been damaged. Is this a clinical problem? As yet there has, of course, not been time enough to find out whether the less efficient kidneys are in a stationary condition or whether they are in a slow process of deterioration. In time the records of physicians and of hospitals ought to throw light on this problem.

One interesting aspect of the nonprotein nitrogen and urea problem is the question as to the effect of the food protein on the level maintained. In the case of strictly normal persons it makes practically no difference whether the diet is rich or poor in nitrogen. In persons having clinically damaged kidneys, the protein content of the food makes a great deal of difference. In many such cases (but not in all) it is possible by means of low nitrogen diets to reduce the nitrogen level of the blood to nearly or quite the normal level. The further elucidation of this point is, I should say, a clinical problem. In this connection one would naturally ask whether it makes any practical difference, or any difference, to the well-being of patients whether they carry a normal or high level of waste products in their blood. This is an obscure problem. As the level of nonprotein nitrogen in blood is raised, the percentage of the urea fraction of that nitrogen increases. When the nitrogen is very high, as in certain cases of threatened uremia, by far the greater proportion of the blood nitrogen (nonprotein nitrogen) is represented by urea.

Urea is believed to be harmless, and it is certainly true that a good many nephritic patients can go about feeling well, and yet carry as much as 100 mg. of urea nitrogen in their blood, while others go into so-called uremic coma without carrying any unduly high levels of nonprotein nitrogen or urea. Uremic attacks with low levels of blood nitrogen happen perhaps most frequently in cases of so-called toxic pregnancy. All this has been known for a long time.

We have lately taken up the study of blood in pregnancy partly for the purpose of verifying the findings previously reported by others, and partly with the hope of being able to advance the subject a little further.

The results which we have obtained have proved rather surprising, and are at least interesting. Our subjects are obtained from the Boston Lying-In Hospital, and we are indebted to Dr. Newell for the privilege. Indeed, the research is essentially a cooperative one between Dr. Newell, Mr. Foster and myself.

We have thus far analyzed the blood of about 100 pregnant women, most of them clinically normal. As yet we have paid attention only to the nonprotein nitrogen and urea. From the class of patients to which these women naturally belong we should expect to find substantially the same rather high level of nonprotein nitrogen and urea as we find in other hospital patients.

Such is not the case. Very few pregnant women, except the toxemic ones, give a nonprotein nitrogen over 30 mg. per hundred c.c. The more interesting fact, however, is that the urea of blood obtained from normal pregnant women is practically without exception very much smaller than the amounts of urea found in other normal human blood. Such other human blood does not contain less than 11 or 12 mg. of urea nitrogen per hundred c.c. The bloods of pregnant women, on the other hand, run between 5 and 9 mg., and very few indeed run as high as 9 mg. of urea nitrogen for 100 c.c. of blood. Whereas in other normal persons the urea nitrogen represents 50 per cent. or more of the total nonprotein nitrogen, in these bloods it represents only from 20 to 35 per cent. of the total.

Several investigators have recently published some observations on blood in pregnancy, and I am at a loss to explain their results. They have, to be sure, found a few low urea figures, but these have been exceptional, and they have thus failed to find this peculiar characteristic of pregnancy.

I would hesitate as yet to try to explain this remarkable phenomenon. The problem is complicated by the fact that we do not possess full information as to the percentage distribution of the nonprotein nitrogen of normal blood. We have been going on the assumption that this nitrogen, so far as it is not accounted for by the ordinary waste products, must be largely amino-acids, that is, valuable food products. This assumption is probably not quite correct, for the figures obtained by Van Slyke's method for amino-acids leave a considerable proportion of the nonprotein nitrogen of blood unaccounted for. Two thoughts naturally suggest themselves in connection with our peculiar analytic findings. A low proportion of urea should leave a higher proportion of amino-acids and other similar products (possibly peptids), and it is conceivable that this is the result of a mechanism for providing a more abundant and constant supply of the kind of nitrogenous food materials needed by the growing fetus. The other thought is this: The pregnant organism may be more susceptible than others to the toxic effects of certain waste products, and in self defense may be compelled to keep these waste products, including urea, at a subnormal level. This thought is rather attractive, for it contains the added hint that the blood in toxemic pregnancies may be abnormally rich in toxic products, even when the total amount of nonprotein blood nitrogen is not very high; from 35 to 40 mg. of nonprotein nitrogen in such blood may be an entirely different proposition from the same amount in other subjects. Whatever the correct explanation may be, the fact itself is, I think, decidedly interesting.

I have already referred once to Abderhalden's pregnancy test. The thought has, of course, occurred to us that urea determinations in the blood may have some diagnostic value with reference to pregnancy. But as yet we have had only a few cases representing the third month of pregnancy and no earlier ones. I therefore make absolutely no claims in this direction.

Before leaving the subject of the nonprotein nitrogen and urea, I ought perhaps to refer briefly once more to the use and value of these determinations as means of estimating the renal efficiency, and to the "refinement" represented by the so-called Ambard coefficient, which is simply a combination of urea determinations in blood and in the urine. The underlying idea of this combination is to eliminate any confusion which might arise because of changes in the blood concentration (in urea) due to the level of the general protein metabolism. In normal persons, as I have already indicated, there is no material change in the urea content of the blood because of changes in the level of the nitrogen metabolism. In nephritics, considerable variations can be produced by changes in the diet; but these changes are produced very slowly so that it usually requires several days of low protein feeding to produce a marked alteration in the urea content of the blood. Yet nephritics, like normal persons, adapt themselves promptly to changes in the protein content of the food, and, like normal persons, tend to remain in a condition of nitrogen equilibrium. The complicated mathematical formulas introduced in connection with the Ambard coefficient do not tend to increase one's confidence in that coefficient. It is difficult to see how square roots and cube roots can help to elucidate such a simple metabolism proposition.

Work along the lines of the Ambard coefficient is one of the researches I had in mind in stating that many metabolism investigations based on metabolism periods shorter than twenty-four hours are now being made. The Ambard period, seventy-two minutes, seems to me, however, to be too short. I believe that a more suitable condition for studying the effects of the metabolism level on the urea retention will be found in connection with the three hour metabolism period to which I have already referred.

Determinations of nonprotein nitrogen and urea in blood have up to date proved the most popular in the study of blood. This is natural enough, at least so far as it concerns clinicians, because these determinations stand for concepts which to them are perfectly clear.

A theoretically equally interesting determination in connection with certain clinical problems should be that of the ammonia. Ammonia determinations in urine have become important in connection with the study of acidosis. Very few, however, have ventured to undertake the determination of ammonia in blood, notwithstanding the fact that it has figured very extensively in attempts to make ammonia responsible both for uremic and for diabetic coma. It is not difficult to see why this field is being neglected. No one recognizes more clearly than I do that the method for the determination of this substance in blood is far from easy. Moreover, the amount of ammonia present in blood is so small that it is difficult to see how these traces can be of much clinical significance. It is an interesting and remarkable fact that even in diabetic acidosis, when the daily urine may contain several grams of ammonia, the concentration of ammonia does apparently remain at an extraordinarily low level in the blood. If any one should here attempt to apply an "Ambard coefficient," he would doubtless be led into the very highest fields of mathematics before a satisfactory formula could be obtained. I sometimes suspect that there is something wrong about our ammonia determinations in blood. Dr. Denis and I have repeatedly returned to the investigation of the subject; we have spent several weeks on it again this year, but as yet have found nothing to indicate that our earlier work is not substantially correct. Henriques, in Denmark, has recently published an apparently very thorough research on the same topic, and has in the main verified our findings. For the present, therefore, the problem of the ammonia in blood remains as before, theoretically interesting, but practically unfruitful.

For several years the determination of creatinin in urine has been used and accepted as an indispensable feature of every metabolism investigation involving urine analysis. In hospital work this determination is absolutely necessary as a check on the work of the nurses. It is the only means we have for detecting gross errors in the collection of the urine. Every other urinary constituent may vary up and down, but the creatinin remains practically constant, so that when a patient's creatinin output begins to show remarkable variations it is time to give up the experiment or begin all over again.

The creatinin in the blood is normally not large, 1 or 2 mg. per hundred c.c. of blood, but it is normally constant and easily determined. I say this advisedly, though I recognize that one investigator has lately published results purporting to prove that the values as ordinarily obtained are several times as great as the true creatinin content of blood.

The creatinin is one of the last waste products to accumulate in the blood as a result of kidney insufficiency. It is apparently only in rather advanced uremic conditions that this product begins to increase in the blood. A great many more observations are needed, however, on this point, and as the determination is easy and simple when a standard creatinin solution has once been obtained, it is a determination which should be taken up by clinicians. The only reason why clinical workers have not already stepped into this field is the fact that pure creatinin, or a pure creatinin salt, is needed for the standard solution which must be used in connection with the colorimetric determinations.

It seems strange that no chemical manufacturer has yet undertaken to prepare creatinin zinc chlorid to meet the demand for this salt.

Pure creatinin can, as a matter of fact, be dispensed with in connection with this determination. It takes only a few minutes' work to determine colorimetrically the creatinin content of normal urine by the help of my older potassium bichromate method. By appropriate dilution of such urine with half normal hydrochloric acid a perfectly serviceable standard creatinin solution is obtained, and this solution will keep for weeks, if not indefinitely, so far as the creatinin content is concerned. The changes which do occur, darkening in color, precipitation of uric acid, etc., do not destroy the value of the solution as a creatinin standard.

Among the waste products of the animal metabolism there is none more interesting, alike to the laboratory worker and to the clinician, than uric acid. From the standpoint of normal metabolism it is generally believed that the uric acid problem is very nearly settled. I am less sure on the subject now that I would have been two or three years ago. The remarkable results reported by S. R. Benedict on the presence of extraordinary quantities of latent uric acid in beef blood, his demonstration of a synthesis of uric acid in Dalmatian dogs, and his findings indicating that the allantoin in dog urine does not represent decomposed uric acid, all indicate that we may yet have to revise in radical fashion views which but a short time ago seemed firmly established. The many vague clinical hypotheses which used to be associated with uric acid have, however, been swept aside. The uric acid crank has all but disappeared from among the medical profession. As a problem of comparative physiology, uric acid is exceedingly interesting, and from the standpoint of both clinical and experimental medicine it is yet destined to be the subject of many investigations.

The human organism has the almost unique distinction among mammals of not being able to destroy any of the uric acid which it produces. The human kidney is also less competent to get rid of this waste product than we could wish. In consequence of this combination of circumstances, the quantitative determination of uric acid in the blood is one of great promise and importance. The method for this determination is of such recent origin that the modern literature on the uric acid in blood is not large, and yet there is already considerable diversity of opinion concerning both the uric acid content of normal blood and the pathologic fluctuations which may occur. How far these differences may be due to imperfections in the analytic method or to lack of skill in the use of the method I am not prepared to say.

It is absolutely certain, however, that some kinds of human blood carry abnormally large amounts of uric acid and at the same time substantially normal amounts of nonprotein nitrogen and urea. It is equally certain that other kinds of blood carry substantially normal amounts of uric acid, yet exceedingly large amounts of total nonprotein nitrogen and urea. The former condition, as was to be expected, is most frequently found in gout, the latter in nephritis. The high uric acid in the blood of the gouty, like the high urea in the blood of nephritics, is due to lack of excretory power on the part of the kidneys and not to increased production of uric acid (or of urea).

With reference to the origin of the uric acid produced within the body, we cannot yet say how large a proportion comes from the muscles and how much from glandular organs. That the glands, at least in proportion to their size, are by far the most important centers of uric acid production follows as a matter of course from our present day teachings and beliefs to the effect that uric acid is formed in or from the nuclei of cells. The validity of this view can be experimentally demonstrated. Even in laboratory animals whose blood and muscles contain very minute traces of uric acid, we find in the spleen, liver, etc., as much as from 10 to 14 mg. per hundred gm. of organ, that is, fully twenty times as much as we find in the blood or the muscles.

I have confined this discussion to a consideration of only a few familiar waste products. As we get into the field of blood and tissue analysis, as we get into experimental touch with the chemical processes going on within the body, we must also begin to pay more attention to products which never find their way into the urine. I must not close without having called attention to the very interesting and promising line of research in the field of the lipoids—a field opened by the application of micromethods worked out by Dr. Bloor. Already Bloor has established the normal relationship existing between these lipoids—fat, lecithin, cholesterol—and the results obtained seem to furnish a basis for a more detailed knowledge concerning the intermediate processes involved in the metabolism of the fats. The extraordinarily practical character of the analytic procedures developed for this work should insure the attention of the clinician, for the fats, no less than the proteins, are associated with many metabolism disorders; I need but refer to malnutrition in infants, pathologic obesity, lipemia, and diabetes.

Before closing I wish also to make just one brief reference to another class of products in the study of which a beginning has been made on the basis of microchemical methods. I mean the phenols. As yet we have not gone beyond the urine, however, in the study of these substances (which, as you know, are chiefly the products of intestinal putrefaction, and at least some of which are distinctly poisonous). I had hoped before this to have definite methods for the determination of phenols in blood, for it is their concentration in the blood, not the amount in the urine, which is significant in relation to diseases. We have run into these products both in connection with studies on epinephrin, which is a phenol, and in connection with uric acid, which in chemical constitution and in many of its reactions is also similar to the phenols. These very similarities are the difficulties against which we have to contend when endeavoring to determine the ordinary phenols in blood. It is a difficult problem, but in time it will be solved.

It will seem to you that I have discussed little else than analytic methods—a subject which cannot be made very interesting outside of the laboratory. I am convinced, however, that both the biochemist and the clinician must pay more and more attention to this least interesting but most important aspect of research. Scientists of earlier generations discovered a great many important facts in the realm of metabolism and of medicine. It will be found on scrutiny, however, that their discoveries were accidental or of such a character that they were bound to be made by one or another reasonably keen observer. That pioneer stage is over. The surface problems have been solved.

It is now only by means of finer and ever finer technic that progress can be made toward the solution of the many metabolism problems which must be solved by us and those who folow us, in order to secure an increasingly better basis for clinical, experimental, and, above all, preventive medicine.

DECENCY AND SAFETY AS PUBLIC HEALTH FACTORS

CHARLES E. NORTH, M.D.
NEW YORK

The detached point of view is often mentioned in modern literature as the property of a few select minds. To be impersonal, to get away from detail, and especially to get away from the narrow point of view of the specialist, is extremely difficult in this age of specialization. The strongest objection that can be raised against specialization is that it anchors the mind in a narrow channel, and creates habits of thought that prevent the specialist from estimating the value of even his own specialty.

The truly scientific point of view should be sufficiently detached to see the relation that things bear to each other in their true proportion. It should be close enough to recognize clearly the character of the data available on special subjects, and distant enough to make a comparison of values. The correct balance must be one that does not overestimate or underestimate.

A survey of the progress that has been made in public health science shows that it has been marked by the rapid development of a number of branches of special knowledge. Public health science has created a new field for the specialist. The chemist, the bacteriologist, the physican, the sanitarian, the statistician and the engineer have all found new territories for the rapid and fruitful development of their specialties. The field of effort is so new that it has been largely unexplored, and the pioneers have found their work as yet uncoordinated, and the value that should be put on it still undetermined.

Numerous important factors have been discovered which contribute in marked manner to the public health. The development of these has not been regular, but irregular, and some have been pushed forward while others have lagged behind. Just what qualifications justify the recognition of a principle as an important factor in public health science is still debatable.

Like other sciences, the science of public health has been accompanied by a background of philosophy, and the philosophers have been divided into a school of realists and a school of idealists. The irrepressible conflict between the practical and the academic is again being fought out in this new realm. In this instance, the issue at stake is of more importance to the vitality of civilization than any previous battle between these two groups of philosophers. There are, on the one hand, those who consider that public health should concern itself only with direct causes of disease. They are pragmatists, and look with some degree of ridicule on their more esthetic opponents. Their slogan is safety. Safety first, it must be admitted, is the foundation stone of public health science. Life comes before health. To this extent the realists are justified in their practical point of view. They are supported by the character of the public health laws that have already been written. They are also supported by the attitude of the courts. To them the main question at issue is always between safety and danger. In their catalogue, public health is concerned chiefly with quarantine as a remedy for epidemics, with sanitation as a remedy for contagion, and with sterilization as a remedy for infection. All they ask of the courts is to enforce the law against those things which are dangerous to health.

On the other hand, there has been a steady growth of the ranks of academic philosophers who are devoted to the cultivation of sentiment. Sentiment and the esthetic sense, they believe, have a value which has been neglected by the school of pragmatists. In their survey of the progress of the race, as well as of the individual, they lay claim to the discovery that sentiment lies at the basis of all joys. Even the desire for life, they maintain, is only a sentiment. They refuse to draw the line sharply between the practical and the academic. They assert that it is the stage that has been reached in the evolution of the species or of the individual which dictates what should be included or excluded from consideration by public health science. They point out that the word "health" is a large word, and that it should include much more than the question of safety. They admit the importance of safety, but assert that safety alone is not enough. They join the framers of the constitution in believing that the individual is entitled, not only to life and liberty, but also to the pursuit of happiness. They firmly believe that the enjoyment of life is just as important as life itself, and that health in its true sense must include "living" as well as existence.

THE ELEMENT OF DECENCY

"Decency" is a word that formerly had a rather limited meaning. In recent years this word has been broadened so as to signify much that contributes to the enjoyment of one's food and drink, and one's surroundings. For example, sanitation has contributed very largely to the decency of dwellings through the removal of objects offensive to the eye, and perhaps also to the nose, although not necessarily directly dangerous to health. Cleanliness of streets and houses and of the environment was formerly urged by the realists in the belief that disease originated mainly in the environment. The discovery that sources of infection are mainly human and animal, and that disease is transmitted for the most part by direct contact, has justified the abandonment of sanitary inspection and sanitation so far as they are concerned with the environment as the cause of disease. Nevertheless, the idealist still insists on cleanliness and sanitation as necessary public health measures. The cleaning of streets and of dwellings will still continue, but not for the old reasons. The sense of decency properly describes the sentiment that at the present time stimulates the carrying out of clean-up campaigns.

A much more important application of the sense of decency is found in relation to food and drink. It is instinctive among well bred people to desire only food and drink that is clean, irrespective of considerations of safety. While this instinct may have had its origin in a race experience that proved the connection often existing between dirt and disease, yet culture has developed this instinct to such an extent that the enjoyment of food and drink is destroyed if these are known to be insanitary.

Legal recognition of the requirements of decency are contained in the federal pure food law, which prohibits the sale in interstate commerce of any food or drink that is "filthy, putrid or decomposed." While these words may have been embodied in the law because they were believed to provide the element of safety, yet they cannot be interpreted otherwise than as words that also include a large element of decency. Filth may not be dangerous, and still be filth. A food that is correctly characterized by all three of the words "filthy, putrid or decomposed" might be boiled or sterilized until it was safe, so far as disease is concerned, but still be unfit for food according to the provisions of this law.

For example, eggs that have become decomposed have been put on the market in a liquid or dried or frozen condition, and have been condemned without positive evidence of danger, but on the ground that they are offensive because filthy, putrid or decomposed.

The single service package is coming into use. Paper wrappings are being adopted for bread, and crackers, and other foods that were formerly dispensed loose. The safety element may also be a factor in this campaign for single service; but in the minds of the consumer the decency element is a much more powerful factor. The consumer prefers clean bread, clean crackers, clean fruit, clean candy, because cleanliness contributes to pleasure in consuming food.

The consumer is entitled to the enjoyment of food and drink, as well as to their being safe. The factor of decency is creeping into health regulations almost imperceptibly. One of the most notable examples of this is the recent adoption of the grading system for the control of municipal milk supplies. In this system milk is graded according to its sanitary character into three grades, labeled A, B and C. In all three grades the milk is pasteurized, and if the process of pasteurization is properly carried out, the milk is entirely safe because those species of bacteria causing disease have been destroyed. Most sanitarians are inclined to believe that as a measure of safety, pasteurization is, in fact, effective in rendering all milk safe, irrespective of its previous sanitary condition. It is true that some experts assert that there may be toxins remaining in unclean milk after pasteurization, or that some spore-forming bacteria outside of the list of recognized pathogenic species may be injurious to infants and children. In general, however, there is good evidence that the differences in safety between milks that are sanitary and insanitary, provided these are properly pasteurized, are comparatively slight. This being so, the question arises, Why should milk be graded? The answer is that the masses of milk consumers have the sense of decency sufficiently developed actually to prefer as a beverage a milk that has had a clean history to a milk that has had an unclean history, even if they know that the two milks are equally safe. Analyzed more closely, this is because there is more enjoyment in drinking clean milk, and less enjoyment in drinking unclean milk.

THE PURITY OF WATER

Of late the esthetic philosophers have brought up the same issue in connection with public water supplies. The words "pure and wholesome" appear in almost all water contracts as describing the quality of the water to be used by municipalities. The definition of the word "pure" as applied to water seems still to be a debatable question. There are apparently many kinds and degrees of purity. The introduction of laboratory tests by chemical methods was at first thought to be a fair means of settling this controversy. The refinement of chemical methods seemed to promise the discovery of all forms of water impurity, so that a water free from impurity could be distinguished from one that had been contaminated in any way. The fallacy of this belief became apparent immediately on the advent of bacterial methods of water analysis. It was soon recognized that water apparently pure by chemical tests might be exceedingly impure by bacterial tests. Sanitarians once more believed that in the bacterial test they had at last discovered a criterion by which the purity or impurity of water could be judged. And now the integrity of the bacterial test as a measure of impurity has been shattered by the advent of methods of sterilization. Chlorinated lime (bleaching powder) or chlorin gas can be applied to any water—no matter how impure or how badly infected with bacteria—and after such application the bacteria will be so completely destroyed that so far as the laboratory test for bacteria is concerned, the water will appear to be practically sterile. Thus, the measurement of purity by the bacterial test can be completely nullified by previous sterilization processes.

It is now a very lively question as to what public health experts mean by the word "pure" as applied to water. For example, if one assumes that a water comes from a surface supply and receives on the watershed large quantities of sewage, but that it is then impounded in a reservoir in which considerable sedimentation takes place, and is then sterilized with hypochlorite solution so that the bacteria are killed, is such a water to be accepted as qualified to receive the designation "pure"? Or, on the other hand, if one assumes that a municipal water supply comes from an uninhabited territory, such as woodland lakes, and receives no sewage from human habitations, and hence no form of treatment is necessary, is such a water more deserving of the term "pure" than the water in the former case?

Most of the cities on the Great Lakes, both in Canada and in the United States, use the Great Lakes not only as sources of water supply but also as mechanisms for sewage disposal. Projecting from one part of the city are pipes discharging sewage into the lakes, and more or less close by, from another part of the same city, extend pipes through which lake water is pumped into the city for drinking purposes. From time to time public sentiment has contended that the two pipe lines were too close together. Chicago actually decided to withdraw most of the sewage from the lake and discharge it into the Illinois River, which flows into the Mississippi above St. Louis, thereby handing the sewage which Chicago citizens disliked to the citizens of St. Louis for drinking purposes. In Cleveland and other cities, public sentiment from time to time has forced the city to extend the pipe line drawing water from the lakes beyond the zone supposed to be invaded by sewage. At Toronto and Milwaukee, systems of purification and sterilization have been installed on the theory that though the sewage is mixed with the drinking water, it can be rendered pure by sufficient treatment. The St. Louis courts, when appealed to, decided that the Mississippi River water, even though polluted with the sewage of Chicago, corresponded to reasonable standards of purity.

The city of Fulton, N. Y., has a public water supply coming from a well known spring, and the streets are sprinkled with the same spring water that is sold in bottles to other municipalities.

It is a fair question to ask whether a distinction should be made between a purity of water due to prevention of contamination, and a purity due to various forms of treatment. From the consumer's standpoint, this question can be judged just as in the case of milk and foods. When the consumer is presented with two glasses of water and informed that both of them are free from bacteria, and can observe that both are clear and free from odor and sediment, and is assured that both taste equally well, the question arises, Will the consumer be prompted to exercise any serious choice when informed that one of these waters was polluted with sewage while the other was not? I think it is reasonable to suppose that the masses of the people have a sense of decency developed to such an extent that without hesitation they will voluntarily choose to drink the water that has never been contaminated with sewage.

It is undoubtedly for this reason that all of the offices of the city hall at Jersey City, N. J., are supplied with bottled spring water for politicians to drink, in spite of the fact that the courts have decided that the municipal water supply of Jersey City is pure and wholesome, though it is contaminated with the sewage of the cities on the watershed, because the water is sterilized with chlorinated lime. It is undoubtedly for the same reason that the office buildings of New York City are supplied with bottled spring water for the business men of New York to drink in spite of the fact that the Croton and Catskill supplies are also sterilized with chlorinated lime. In these instances, the politicians and business men referred to seem to have allied themselves with the ranks of the esthetic philosophers, as opposed to the pragmatists.

THE DETERMINATION OF DECENCY AND PURITY

But our friends among the pragmatists are prepared to assert that there is no practical way of determining purity in the esthetic sense. They will maintain that the courts cannot recognize the sense of decency because regulations cannot be written in such terms. They are inclined to limit our public health propaganda, not only to measures of safety, but also to standards of cleanliness that can be determined by the chemical and bacterial laboratories. They assert that there is no other method of measurement feasible, and that public health officials and the courts cannot give consideration to distinctions that are purely academic. For example, cow manure in milk is academic, or sewage in water is academic, if the quantity cannot be accurately determined by chemical or bacterial tests. The answer to this objection, so far as the courts are concerned, is that the courts can always apply the general method of measurement that is commonly used by them in determining the meaning of other defining words. This method consists in the use of the meaning commonly accepted by the masses of the people. For example, if the word "pure" as applied to water means "free from sewage" in the minds of the masses of the people, and this feeling is so strong that the masses of the people prefer to drink a water free from sewage to a water that has been contaminated with sewage, the courts will accept this attitude of the people as a proper means of determining the significance of the word "pure" as applied to water. The degree of importance that must be attached to the element of decency as it relates to any particular thing can at any time be determined by testing public sentiment on this subject.

What attitude should the leaders in public health science take with regard to decency as a public health factor? Shall they encourage the development of the sense of decency on the part of the public as a desirable thing, and as something that can be applied to public and private environment, and to food and drink, in a way so practical that a reasonable degree of decency can be enforced by public officials? Or shall the leaders in public health science conclude that decency is academic, and that the esthetic sense has no place in the list of considerations on which the activities of public health officials are based? If health means more than life, if health includes the enjoyment of life, if health is to include the enjoyment of one's environment, and the enjoyment of things one eats and drinks, then public health administration cannot ignore the demands of common decency in the steps that it takes to safeguard public health.

The progress of the people toward better things seems to be constantly marked by improved sanitation. Public sanitation and private sanitation contribute directly and indirectly in so many ways to better living, better thinking and better working that they seem to be an essential part of the process of development. Whether or not the workers in public health science recognize decency as an important factor in public health science, the common people themselves have already given decency such recognition. The reason the instinct for cleanliness and decency has developed with the race is that these contribute in a marked degree to the satisfaction of living. If public health includes anything more than the element of safety, then decency for its own sake deserves a place in the catalogue of public health administrators.

30 Church Street.

Marching.—While the present war especially in the western regions has involved much trench fighting, besieging, etc., it must be borne in mind that marching still occupies much of the soldier's time, much more than does combat. This is clearly seen in the Russian campaigns. For this reason it is of prime importance that the soldier be able to march well. The general public have a mistaken idea of the length of a heavy march, the tendency being to place the estimate altogether too high. A fair day's marching for any army is 12 miles. The strenuousness of the march depends to a large extent on the size of the marching force. A good day's march consists of 15 miles while 20 constitutes a forced march. Quick time for the English armies consists in about 120, 30-inch steps per minute, which gives 100 yards per minute. From 2½ to 3 miles per hour is good marching. It takes a brigade six hours to march 15 miles while a division needs eight for the same distance.—Hygiene and War, by George Ellis Jones, Ph.D.

TREATMENT OF CHANCROID *

FREDERICK W. ROBBINS, M.D.
Fellow of the American College of Surgeons
AND
FRANK P. SEABURY, M.D.
DETROIT

We recognize four clinical varieties of chancroid:

1. Ulcus molle, the ordinary variety of ulcer, has the characteristic punched-out appearance, with edges cleancut and often undermined.

2. Ulcus molle miliare begins as a small papule, which rapidly becomes a pustule, the center of which is a deep craterlike ulcer. It occurs most frequently on exposed surfaces in the loose skin, just posterior to the mucocutaneous junction of the prepuce in man and about the labia majora and the perineum in woman.

3. Ulcus molle elevatum is the sore most frequently confused with indurated chancre. Its incubation period is from nine to twenty-one days. The sore is slightly raised above a mildly infiltrated base. The edges are not undermined, and it has little tendency to spread. This form is resistant to ordinary treatment and is prone to persist for from four to eight weeks.

4. Ulcus molle phagedenicum is the most severe and the most resistant form with which we are familiar, and occurs as a complication of both chancroid and syphilis. It spreads rapidly, is made worse by any half-way measures, and, unless checked early, is capable of destroying a part or even the whole of the penis.

To these McDonagh adds a fifth classification, the ulcus molle serpiginosum. This ulcer may occur as a complication of bubo or it may begin as a furuncle in the groin. It is found chiefly in the tropics, is highly resistant to all forms of treatment, and frequently remains a slowly spreading ulcer for years. We have never encountered it in this country.

The treatment of chancroid, at the best, is unsatisfactory, as is evidenced by the great variety in the methods of treatment advocated by different authors. If seen early, a fair percentage of patients do well under nearly any antiseptic treatment, particularly if they are cleanly in their habits. In fact, we believe that 60 per cent. of chancroids, taken as they come, of anywhere from two days to two months' duration, will heal in from four to eight weeks with no treatment except rigid cleanliness, a little calomel, or other dusting powder, if the sore is within the preputial cavity, or a moist dressing of black wash if the sore is exposed. If seen within the first two or three days, thorough cauterization with nitric acid is quite successful, but great care must be used not only to destroy completely every sore, but to keep the surrounding tissue covered with an antiseptic until healing of the cauterized areas is complete.

It is the sores that are not seen early, or that are not favorably influenced by cauterization, which cause the trouble and for which we have never been able to find in the literature a thoroughly satisfactory method of treatment.

Zinc ionization gives good results, but requires special apparatus and consumes considerable time. Argyrol crystals applied directly to the sore for three

---

* Read before the Section on Genito-Urinary Diseases at the Sixty-Eighth Annual Session of the American Medical Association, New York, June, 1917.

or four minutes, followed by a moist dressing of 10 per cent. argyrol or 1 per cent. protargol, have been satisfactory in a few cases; in others they have not even checked the spreading of the ulcer.

A satisfactory method of treatment for the large majority of cases of chancroid in the preputial cavity is the thorough application of a 25 per cent. solution of copper sulphate crystals in water. The ulcer is first anesthetized with a 10 per cent. cocain solution and then lightly curetted with an applicator wound firmly with cotton, after which the copper solution is applied. It is left in contact with the sore for three or four minutes and then sponged off. On the dry sore a light dusting powder, calomel or a morphin-narcotin mixture is used, and one or two thicknesses of gauze, moistened with black wash or tap water, are applied and the foreskin drawn forward over the whole. This is changed two or three times daily; and every second day, unless granulation is progressing satisfactorily, a 10 per cent. solution of copper sulphate is applied. The majority of chancroid ulcers do well under this treatment, but from 15 to 20 per cent. tend either to persist many weeks, or to grow gradually larger and deeper in spite of treatment. The direct cause is the failure to sterilize the wound.

RESULTS OF AUTHORS' METHOD OF TREATMENT IN THIRTY-FOUR CASES

Case No.	No. of Lesions	Incubation Period	Previous Treatment	Duration Before Fulguration	Darkfield or Stain	Diagnosis*	Number of Treatments with Violet Ray	Healed	Bubo	Wassermann	Remarks

* Names in diagnosis column: U. M., Ulcus molle; U. M. M., Ulcus molle miliare; U. M. E., Ulcus molle elevatum; U. M. P., Ulcus molle phagedenicum.

In order that a method of treatment of chancroids may be regarded as satisfactory, it must not only effect a complete sterilization of the sore and thereby a cure of practically all cases within a reasonable length of time, but in order to be available to the large majority of physicians, it must also be comparatively simple in form and means of application. Such a method, or combination of methods, we believe we have devised, and we base our conclusions on the observation of about sixty cases during the past year. In this series we have had practically 100 per cent. of early cures.

Regardless of the appearance, duration or previous treatment of a venereal sore before it is destroyed, it is always examined for spirochetes.

If antiseptics have been used, it is our custom to apply a moist dressing of cotton wet with tap water for from twenty-four to seventy-two hours, during which time two or three microscopic examinations are made. If no treatment has been previously given, the examination and destruction of the sore is accomplished at the first visit.

A small pledget of cotton is wet with 10 to 20 per cent. solution of cocain and applied to each lesion. After four or five minutes the field is carefully cleansed with soap and water and dried. Each lesion is then thoroughly wiped out with a cotton wound applicator until bleeding ensues. This is arrested by sponging, and when only serum exudes from the wound, this is collected for examination by dark field or stain, as may be the choice of the operator.

A 25 per cent. solution of copper sulphate in distilled water is now applied to the sore, and the short high frequency spark from a rather fine-pointed vacuum electrode is applied directly to the sore for one to three minutes, depending on the extent of the ulceration. Especial care is exercised in carrying the point of the electrode well down into any fissure or undermined edge, and the area of application should extend over the edge of the sore about one sixteenth inch into the doubtfully healthy area.

The current is not turned off until every crack and crevice has been thoroughly treated and the surface of the sore is changed to a dark greenish gray. It is then wiped dry and some antiseptic powder is lightly applied to the entire mucous surface of the preputial cavity. If the sore is exposed, it should be covered with a thick moist dressing, for which any very dilute antiseptic solution may be used, as a 1:10,000 or 1:20,000 mercuric chlorid solution; or even tap water answers nicely in most cases. This should be changed once or twice daily, and must not be allowed to stick.

The patient is instructed to return in two days, and, if the work has been carefully done, the wound will present a perfectly healthy granulation that will go on to complete healing in a few days. If the sore does not look clean, the application is repeated at the second visit. The patient returns each second day. If the original sore was large, or if a small sore does not seem to be closing rapidly, we have made it a practice to apply, at each visit, either a 10 per cent. copper sulphate or a 5 per cent. silver nitrate solution. We do not hesitate to repeat the original cauterization at any time we have reason to think the chancroidal infection is not completely eliminated.

The complete success of this, as of any other method, is dependent on careful, thorough work. There is more danger of too little cauterization than of too much, and thorough cleansing at the time the sore is destroyed must not be forgotten. Again, the after-care, especially with ulcus molle outside the preputial cavity, and with ulcus molle miliare, is of the utmost importance. If one fails to carry the electrode to the bottom of the cavernous ulcer, then one is lost. It heals over the surface, and in two or three days breaks out anew, larger and deeper than before.

If the dressing on an exposed surface is not changed once daily, and moistened at least three or four times, in many cases one will not succeed.

The accompanying table gives our results in all cases in which data are complete. A number of patients failed to return after the first treatment. Several of these have been seen later, and reported uneventful healing in a few days. In no case have we been able to record a failure.

Three or four cases in which the lesions did not heal well or recurred later developed a positive Wassermann reaction, notwithstanding the fact that careful microscopic examination was negative for spirochetes.

To be thoroughly scientific, one should always be able to explain and prove the modus operandi of any treatment presented to the profession. Unfortunately, we are not able to do just that, but we believe that by this combined treatment we have been able to produce deep sterilization of the chancroid ulcer with a certainty not heretofore effected. This has been done with great satisfaction to ourselves and our patients. We present the method with the hope that our friends may find in its application the same assurance of success that we enjoy.

1212 Kresge Building.

ABSTRACT OF DISCUSSION

Dr. Noah E. Aronstam, Detroit: The method of procedure in the treatment of chancroids as outlined by the essayists is neither novel nor unique. Old French authors on the subject as far back as 1880 advocated the use of strong solutions of copper sulphate. In the Allgemeine Krankenhaus of Vienna the same method was pursued twenty-five years ago. In the issue of 1902 of the *Russkiy Vratch* a similar method was mentioned.

The use of the high frequency tube on the lesions after the preliminary cauterization with copper sulphate is somewhat obscure and questionable to me. A pellicle is formed after such procedure on the sore, and hence the violet ray is unable to diffuse or penetrate and thus sterilize the lesion. My experience has been that it requires an untreated and unmolested lesion in order that the ray may prove efficacious.

As regards the varieties of chancroids, I am in the habit of classifying them as follows: (1) simple erosive chancroid; (2) miliary ulcer, or ulcus erosive miliare; (3) serpiginous form; (4) phagedenic; (5) pultaceous or necrotic; (6) gangrenous.

In the last four varieties the prognosis is unfavorable; the lesions prove very obstinate. Even in the simple variety a definite prognosis cannot always be ventured, and we should be guarded in expressing a decided opinion. There is no uniform method by which we can accomplish results. In my hands equal parts of phenol and iodin have proved useful. I refrain from using such caustic agents as strong solutions of silver nitrate, nitric acid and the methods promulgated by the authors for fear of inducing an indurated condition which may closely resemble the primary lesion of syphilis and thus mask and obscure the clinical features of the sore.

I wish to lay stress on the employment of bacterins in chancroidal lesions. I use a mixed staphylococcus vaccine, as frequently the chancroid harbors a mixed infection, superimposed on its causative agent, the Ducrey-Unna bacillus. I also desire to object to the term "chancroid." It should be changed to infective venereal ulcer, and the inadequate and antiquated term "chancroid" should be abolished.

Dr. H. L. Kretschmer, Chicago: The results that Dr. Robbins obtained with his combination treatment are better than the results we have obtained. We have been using the copper in 25 per cent. solution, preceded by 95 per cent. phenol, then applying the wet dressings just as he has done; that has given us very satisfactory results. I should like to ask Dr. Robbins how much of his good results he attributes to the action of the caustics and how much to the action of the high frequency current. I should like to ask whether or not in any of the cases of multiple chancroids he cauterized some of the lesions with copper and used high frequency, and treated some with the high frequency alone.

Dr. Charles W. Bethune, Buffalo: I should like to ask Dr. Robbins whether he obtained his high frequency current from the regular, standard high frequency machine which we use in fulguration, or from one of these small machines costing about $35. Is the latter sufficient to cause the penetration of the copper sulphate?

Dr. Robbins mentioned the use of mercurials in the treatment of chancroids. One can never tell absolutely that there is not a double infection with the spirochete. In that case one may mask the secondaries, possibly the general adenitis, and very probably the Wassermann reaction.

Dr. B. S. Barringer, New York: Dr. Livermore of Memphis, Tenn., sometime ago suggested that an ounce of argyrol crystals would cure all the chancroids in the United States, if properly applied. That was a rather vigorous statement, but we at Bellevue started to use the argyrol treatment. The ideal way that we found to use it was to cocainize the chancroid first and put argyrol crystals directly on it. Our results have been so good that we have practically given up every other form of treatment. We are rather inclined to agree with the gentleman who first published this statement.

Dr. Leland J. Boogher, St. Louis: This subject has been the *bête noire* of all of us. I have seen some cases that I did not believe any form of treatment would touch, and I remember one or two cases that ran on for a year or two until the tissue was almost entirely denuded. I have used crystals of argyrol and also another proprietary silver preparation. There are some cases in which I would like very much to have Dr. Robbins try his form of treatment. I have one such patient now, whom I have been treating about three months, and he is getting worse every day.

Dr. G. G. Smith, Boston: No one has yet mentioned the use of the actual cautery for very severe forms of chancroid, and I should like to mention it as having been in our hands a real weapon of reliance in cases which were not to be cured by applications of phenol, nitric acid and other caustics. We have had to anesthetize the patient either locally or by gas, and then apply the actual cautery until the whole thing is burned out to a dry crisp. I have seen some chancroids which resisted one treatment of that kind, but a second treatment always cured them.

Dr. Irwin E. Colgin, Waco, Texas: I have used a high frequency spark, using an electrode which approached the roentgen ray, and have had some very good results, but I think Dr. Robbins' method is superior to this, due to the fact that the copper in 25 per cent. solution will act as a conductor. The ordinary effleuve from a high frequency electrode, using a long spark, cauterizes the surface, and I do not doubt that using an electrode in conjunction with the copper sulphate in 25 per cent. solution would cause the current to be carried to a greater depth and would sterilize deeper than if the electrode were used by itself.

Dr. F. W. Robbins, Detroit: In this class of cases we have tried copper sulphate, Dr. Morton's use of zinc chlorid, high frequency—all these various things alone, without unusual results. Is there any one here who has not seen a chronic ulcer of the inguinal region, after a bubo has been opened, that has run on and on, the patients looking tuberculous and the condition continuing in spite of everything done? One such patient was in the hospital and in bed from four to six weeks. We used argyrol crystals and tried to cleanse that wound as thoroughly as possible, but without success as far as results were concerned; the patient simply remained in the same condition with this miserable sore that would not heal. Within a week after combined treatment was instituted the ulcer had healed and he was well.

Dr. Aronstam mentions the former use of copper; that is all right; but whether they used any strong metalic caustic in connection with the high frequency I very much doubt, because in those days they had no knowledge of high frequency or violet rays.

As to the machine from which we obtained this current, I use the Wappler larger battery; Dr. Seabury uses the smaller portable one. One is just as effectual as the other.

Insurance Company Studies Automobile Fatalities.—The Metropolitan Life Insurance Company has made a statistical study of the death rate from automobile accidents which discloses the fact that the mortality rate from automobile accidents has more than trebled since 1911. In 1911 the death rate from this cause was 2.3 per hundred thousand; in 1916, it increased to 7.4. The rate for 1916 shows an increase of more than 37 per cent. over that of 1915. Nearly one third of those killed are children under 10 years of age. Another condition developed by this study is the fact that so far as the industrial population is concerned, more deaths are caused by automobiles than by surface cars, subway trains, elevated trains, bicycles and horse-drawn vehicles combined.

A MORE DELICATE WASSERMANN REACTION DEPENDING ON THE USE OF INCREASED QUANTITIES OF BLOOD SERUM *

P. T. BOHAN, M.D.

AND

L. A. LYNCH, M.D.

KANSAS CITY, MO.

This paper is based on observations made on 200 patients examined serologically for evidences of syphilis. The work done has covered a period of one and one-half years. The material was obtained from the medical wards of St. Margaret's Hospital. The data given represent our effort to develop a Wassermann technic which would check up in a larger percentage of cases with the clinical diagnosis of syphilis and which would enable us to attach some significance to the negative Wassermann reaction.

Our method consists essentially in the use of graded increasing amounts of blood serum and spinal fluid, each serum being tested in the following amounts: 0.1 c.c., 0.3 c.c., 0.5 c.c. and 1 c.c., while amounts of spinal fluid as high as 10 c.c. are used in a single test.

Our investigation shows that as much as 1 c.c. of serum may be safely used, and that a negative reaction with 0.1 or 0.2 c.c. of serum is of little or no value in excluding syphilis in the latent or inactive stage, such as locomotor ataxia. In the cases here reported, which required the use of increased amounts of serum to obtain a positive reaction, the diagnosis of syphilis could be made by other means, such as a history of chancre, the clinical findings and by tests of the spinal fluid. In fact, in not a single case that gave a positive reaction only when as much as 1 c.c. was used did we fail to obtain positive findings in the spinal fluid, such as a positive globulin test, a typical colloidal gold chlorid test, as well as a positive Wassermann reaction when a sufficient amount of fluid was used. Seldom, however, was it necessary to use to exceed 5 c.c. of spinal fluid.

Lange,[1] in 1912, was using as high as 10 c.c. of spinal fluid for a single reaction, but he was not using large amounts of blood serum. Kromayer and Trinchese[2] were using as high as 0.4 c.c. of blood serum in 1913, obtaining more specific results than with the smaller amounts.

We have tested over 2,500 blood serums in amounts as high as 1 c.c. This report is made on but 200, which we checked up by a complete examination of the spinal fluid, a complete clinical history and a careful physical examination.

Of the 200 cases, 143 were known syphilitic. There were forty-one cases of paresis, forty-eight of tabes dorsalis, twenty-nine of cerebrospinal syphilis, seven of congenital syphilis and eighteen cases of syphilitic heart involvement. Eighty-three of these gave complete inhibition of hemolysis with 0.1 c.c. of blood serum; twenty-two gave partial inhibition when 0.3 or 0.5 c.c. was used. In fifteen there was no inhibition until done with 0.5 c.c., and in eighteen cases it was necessary to use 1 c.c. before any degree of inhibition was noted. Six blood serums were negative when 1 c.c. was used. Five of these were long standing inactive cases of tabes, the other being a case of congenital syphilis.

---

* Read before the Section on Pathology and Physiology at the Sixty-Eighth Annual Session of the American Medical Association, New York, June, 1917.

[1] Lange: Berl. klin. Wchnschr., 1912.

[2] Kromayer and Trinchese: Med. Klin., 1912, 8, 404.

It is to be noted that if only the ordinary small amounts of serum had been used, a total of but 59 per cent. positive would have been obtained; while, when 0.5 c.c. was used, the percentage was increased to 74 per cent., and if an amount as high as 1 c.c. was employed, 96 per cent. gave fixation of complement. This is a degree of specificity which has not heretofore been approached.

Of the 200 cases, forty-seven gave no suspicious history, and there were no physical findings suggesting syphilis. None of these gave any inhibition of hemolysis with 0.1 c.c. of serum; two gave a ++ reaction with 0.3 c.c., and ++++ when 0.5 c.c. was used. These were, clinically speaking, cases of chronic nephritis. Three gave complete inhibition of hemolysis with 0.5 c.c. One of these patients had auricular fibrillation, one had typhoid fever, and the other nephritis. Two gave a partial inhibition with 1 c.c.; one was a patient with multiple sclerosis, and the other was a pneumonia patient. One gave complete fixation of complement with 1 c.c., negative in less amount, this being a case of multiple sclerosis. There were, of course, cases of latent syphilis.

It is of especial interest to note that in those patients in whom we obtained a positive complement fixation reaction with the use of increased amounts of serum, both in the group of known syphilitics and those presenting no evidences of syphilis, a precipitation of the gold has always been obtained in the tubes characteristic of the syphilitic curve, along with a demonstrated increase in globulin and an increased cell count in those instances that manifested any activity of the process. Also a positive spinal fluid Wassermann test was obtained in all the instances in which the blood was positive with increased amount, in some cases as much as 10 c.c. or more of spinal fluid being required. It is often possible and practical to determine the minimal amount of spinal fluid necessary to use in obtaining a positive Wassermann reaction by the intensity of the colloidal gold chlorid test and the amount of globulin present.

The complement fixation test is essentially a quantitative one, probably dependent on lipoid substances resulting from antibody formation. The concentration of these substances depends on the activity of the process; hence the frequency of the negative reaction in those cases of long standing in which scar tissue is the immediate cause of the symptoms and the spirochetes to a certain degree inactive, as in tabes dorsalis. It is in this group of cases that, by the use of increased amounts of serum, we are able to obtain a larger percentage of positive results than we would with 0.1 or 0.2 c.c. of serum, which contains an insufficient amount of reacting bodies.

This technic indicates a more definite guide in the control of treatment, a graded increasing amount of serum being required to produce fixation of complement, depending on the intensity of the treatment. We have, of course, those cases of the latent and tertiary states in which prolonged, intensive treatment has failed to diminish the degree of complement fixation; however, it is the rule that cases under treatment become negative in the smaller amounts of serum first, requiring much longer courses to become negative when 1 c.c. is used.

REACTIONS WHEN INCREASING AMOUNTS OF BLOOD SERUM WERE USED

	Quantity of Serum Used				Remarks
	0.1 c.c.	0.3 c.c.	0.5 c.c.	1 c.c.	
Congenital syphilis, 7 cases:					Examination of spinal fluid showed positive globulin, typical gold curve and positive spinal fluid Wassermann in all cases. In two cases 5 c.c. of spinal fluid had to be used to obtain a ++++ reaction. In four cases cell count was below ten to the cubic millimeter. In only one case was the cell count above twenty-five.
1 case	++++				
1 case	++	++	++++		
3 cases	Negative	Negative	++	++++	
1 case	Negative	Negative	++	++++	
1 case	Negative	Negative	Negative	Negative	
Tabes dorsalis, 48 cases:					Diagnosis of tabes made by clinical manifestations and physical findings, increased globulin, typical gold and positive spinal fluid Wassermann in all cases. In 34 cases spinal fluid Wassermann was positive with 0.5 c.c. Largest amount required 5 c.c. In 22 cases cell count was below 10 to c.mm. Only 4 cases had counts above 50 to c.mm.
24 cases	++++				
10 cases	++	++	++++		
3 cases	Negative	+++	++++		
1 case	Negative	Negative	+++	++++	
5 cases	Negative	Negative	Negative	++++	
5 cases	Negative	Negative	Negative	Negative	
Paresis, 41 cases:					Clinical diagnosis made in all cases. In thirty, spinal fluid Wassermann was positive with 0.5 c.c. In only 6 cases was it necessary to use more than 1 c.c. Paretic curve with all cases and an increase in globulin. In but 4 cases was the cell count below 25 to c.mm.; in 12 it was above 100 c.mm.
38 cases	++++				
2 cases	++	++	++++		
1 case	Negative	Negative	++	++++	
Cases with heart involvement, 18 cases:					All were cases of aortic insufficiency. All gave precipitation of colloidal gold in syphilitic curve with increased globulin, and in 5 there was no increased cell count.
8 cases	++++				
4 cases	++	++++			
1 case	Negative	Negative	++++		
2 cases	Negative	Negative	++	++++	
3 cases	Negative	Negative	Negative	++++	
Cerebrospinal syphilis, 29 cases:					Diagnosis made by clinical manifestations and physical findings. Positive spinal fluid Wassermann in all. In fourteen cases it required more than 1 c.c. The colloidal gold test was positive in all cases, with increase of globulin. The cell count was below 10 to the c.mm. in 8 cases. It was above 75 to the c.mm. in but 4 cases.
10 cases	++++				
1 case	+++	+++	++++		
3 cases	++	++	++++		
1 case	Negative	+++	++++		
2 cases	Negative	Negative	++++		
2 cases	Negative	Negative	++	++++	
3 cases	Negative	Negative	Negative	++++	
1 case	Negative	Negative	Negative	+++	
6 cases	Negative	Negative	Negative	++	

Concerning the significance of a serum becoming negative with 1 c.c. of serum during the course of treatment, we can only say that this means much more than when only the ordinary small amount is used.

TECHNIC

At least 10 c.c. of blood should be obtained and as much spinal fluid as can be taken with safety, from 10 to 15 c.c., if possible. After the blood is centrifuged and the clear serum inactivated, it is transferred to a small centrifuge tube to which is added 0.1 c.c. of pure undiluted thoroughly washed sheep corpuscles, shaken and allowed to stand for one-half hour in the ice chest. The serum is again centrifuged, throwing down the sheep corpuscles, and the clear serum pipetted off ready for the test. In this way natural antisheep hemolysin is removed by absorption.

A titration for the proper unit of complement is made with a 2.5 per cent. suspension of sheep corpuscles, a known titer of immune rabbit serum and a 1:10 dilution of fresh guinea-pig serum. This is done in the presence of the different amounts of serum or spinal fluid to be used in the test: in the case of blood serum, 0.1, 0.3, 0.5 and 1 c.c. The serum is taken from a known negative case. When working with spinal fluid, the titration is done for amounts as high as 10 c.c. The spinal fluid being hypotonic for sheep cells, it becomes necessary to add sufficient sodium chlorid to make an isotonic solution.

The proper units of complement having been determined, the tests are set up, each serum being run in the amounts mentioned, namely, 0.1, 0.3, 0.5 and 1 c.c. Two units of complement are used for each different amount of serum, and each individual amount is controlled for anticomplementary properties. An alcoholic extract of human heart muscle, to which was added 0.2 per cent. of cholesterin, was used as antigen in this technic. Sufficient 0.9 per cent. salt solution is added to each tube, so that when the test is complete there will be 4 c.c. in each, for it is for this total amount that the titration for the complement unit is made.

One and one-half hours in a water bath at 37 C. is allowed for the fixation of complement, after which the unit of amboceptor and the sheep cells are added, and the final readings are made at one-half hour intervals for two hours. It is to be noted that with the larger amounts of serum the end-reaction is slower in taking place, but with an active amboceptor the final reading can safely be made at the end of two hours.

CONCLUSIONS

1. With larger quantities of serum a higher percentage of positive reactions is obtained.

2. With this technic, if the serum is fresh, 1 c.c. is not more anticomplementary than smaller quantities.

3. Normal serum does not cause complement fixation when 1 c.c. is used.

4. Our investigations corroborate the statement by Lange that in nonsyphilitic cases negative reactions are obtained in the spinal fluid with 10 c.c.

5. A negative reaction with an increased quantity of serum does not positively exclude latent syphilis. In 4 per cent. of known syphilitics there was no inhibition of hemolysis when 1 c.c. of serum was used.

6. A Wassermann test made with graded quantities of serum is not only an index of the activity of the syphilitic process, but is of value in indicating the progress of the case under treatment.

ABSTRACT OF DISCUSSION

DR. B. GRUSKIN, Chicago: No doubt much significance should be placed on any modification in the technic of serologic tests, and any change in the technic that will lead to clearer and better understanding should be encouraged; but there is a limit to this and one must be sure before adopting a new technic whether this is not misleading to a certain extent. From what I gathered from the paper I see nothing different than the original complement fixation test, and the reason the laboratory men decided to use small quantities is because a lot of negative cases had proved positive when large quantities were used. I do not doubt the essayists' statements, but I know that I have tried the same technic in using large quantities and I have obtained slightly positive results in negative serums, due to the fact that large quantities of serums will bind complement to a certain extent. In conclusion I wish to say that unless there are clinical manifestations, or when the spinal fluid shows a high cell count, one must be very careful in pronouncing a case positive when large quantities of serum are used.

DR. J. W. SMITH, JR., New York: What was the amount of serum used in the serum control?

DR. S. S. HINDMAN, Toledo, Ohio: In these Wassermann tests with large quantities of serum, was the active serum used, making use of the native complement? I did not understand this point.

DR. JAMES EWING, New York: It is interesting to note the constant appearance of new serologic tests for syphilis. I have often wondered why some one did not revive the old Justus test, which consisted in a sudden drop in the hemoglobin following a mercurial inunction. This test enjoyed considerable vogue at one time. The great limitation to the significance of all these tests is that they are not specific. So long as their application is restricted to clinical medicine they may be of much service, but when the attempt is made to establish new rules regarding syphilitic infection and immunity or new conditions as to syphilitic origin, they must be rated as unsafe guides. Not long since it was announced, on the basis of Wassermann reactions, that syphilis insontium could be transferred to the third generation. In order to avoid serious errors I think pathologists in general feel that there is only one way of positively establishing the syphilitic nature of a lesion, and that is by the finding of *Spirochaetae pallidae* in the tissues.

DR. LLOYD D. FELTON, Baltimore: Instead of using a great amount of serum I have decreased the dose of complement. The Wassermann reaction is a quantitative fixation of the complement, so that the greater the amount of the complement used the greater the amount of the antibody needed to give a positive reaction. In the use of the method suggested by Bronfenbrenner—hypersensitive cells, these cells hypersensitized by 5 to 8 amboceptor units—one is able to reduce the dose of the complement to 0.01 c.c. of a 1:10 complement. This technic, in my mind, is equivalent to using a large amount of serum. The objection that this technic would make the test too sensitive cannot be sustained. It is not a question of giving too many positive reactions, but the danger of getting a negative result in serum which really is from a case of syphilis. As a rule it is easier to rule out a nonspecific positive reaction from a clinically negative case and much safer than to prove an individual has syphilis when the Wassermann reaction is negative.

DR. L. A. LYNCH, Kansas City, Mo.: From the beginning of this work we have been particularly watchful for nonspecific reactions. Although the technic described has been used with good results on over 1,000 blood serums and spinal fluids, we have included in this report only 200 cases, which have been checked up by a complete examination of the spinal fluid, physical findings and clinical history. We can safely say that when one is working with a hemolytic system with which he is perfectly acquainted, 1 c.c. of normal blood serum does not cause fixation of complement. The serum and spinal fluid are controlled in each of the different amounts used; also the serum is always inactivated. Both complement and amboceptor are titrated for each different amount of serum and spinal fluid used. Observing the necessary precautions, one can safely use larger amounts of blood serum and spinal fluid, obtaining a much larger percentage of positive results in true cases of syphilis.

THE ETIOLOGY AND DEVELOPMENT OF NEPHRITIS *

WILLIAM OPHÜLS, M.D.
SAN FRANCISCO

Before entering on a discussion of my subject I wish to state that I have included in the scope of this paper only cases in which the renal tissue showed well marked diffuse hematogenous inflammatory lesions. I have excluded all focal lesions of lesser importance, whether abortive forms of true nephritis, as the embolic focal nephritis described by Löhlein[1] and Baehr,[2] or other focal conditions which are coincident with vascular disease and in which the disease of the blood vessels evidently constitutes the more important feature.

The cases here spoken of are those which may be designated as cases of diffuse glomerulonephritis, because the inflammatory lesions of the glomeruli play an important part in this disease and form the one connecting link in an often bewildering multiplicity of other developments. The more I study the situation both from an etiologic and a broad anatomic point of view, the more I become impressed with the more general applicability of this old term of glomerulonephritis, not only to those cases that have been commonly so designated (chronic parenchymatous nephritis, secondary contracted kidney), but also to many of those that used to be attributed to primary changes in the interstitial tissue (chronic interstitial nephritis, primary contracted kidney), or to primary changes in the blood vessels (arteriosclerotic nephritis). In this light, these various types of nephritis become mere different manifestations of one and the same disease. The differences that have been so carefully studied by the pathologic anatomists and have given rise to our complex, and, it must be acknowledged, often confusing nomenclature, naturally remain, but as purely descriptive subdivisions. They should be relegated to that point of relative importance to which they may still lay claim, and should not be permitted to cloud the real picture by the introduction of a mass of perhaps interesting but evidently subsidiary detail.

The idea that bacteria might be concerned in the production of nephritis may be said to date back almost as far as bacteriology itself. It found its simplest expression in an inaugural dissertation of Ernst,[3] who worked under Klebs in Zürich, in which it is stated that true nephritis, being a genuine inflammation, was probably due to infectious agents. The support given this theory by Ernst's actual observations naturally was far from adequate. He reported two cases of acute nephritis in pneumonia in which he demonstrated bacteria in microscopic sections of the kidneys and similar findings in an instance of chronic parenchymatous nephritis. It may be stated here that the more careful histologic examinations of a later date have failed to furnish additional proof along these lines except in rare, unusually severe cases, and bacteria, if they were present in sections, were observed not so much in the tissues as in the blood contained in the blood vessels as a part of a general septicemia.

Even before Ernst, in 1880, Kannenberg[4] had called attention to the fact that pathogenic bacteria might be encountered in the urine in cases of acute infectious diseases, "especially when they were associated with nephritis." Kannenberg also seems to have been among the first to emphasize the fact that tonsillitis is a very common cause of nephritis, and he says that in three such cases he found micrococci in close connection with the casts, with the epithelial cells and free in the urine, an observation which recently has been reported as somewhat of a novelty. Ten years later, Agnes Blum,[5] working under Eichhorst in Switzerland, made a careful study of the relation of various acute infections to nephritis, mostly of the acute type, but she expresses the opinion that infections may perhaps be more frequently the cause of chronic diffuse nephritis than was then commonly believed, and she mentions a case which clinically appeared to be one of chronic interstitial nephritis following repeated attacks of tonsillitis, and mentions a similar case, anatomically confirmed, following rheumatism and endocarditis.

In the same year (1890) some interesting experimental work was done by Mannaberg[6] with streptococci isolated from the urine of patients with acute nephritis of obscure origin. By means of intravenous injections of the cultures so obtained, he reproduced severe acute nephritis in dogs and in rabbits. Mannaberg had an idea that these streptococci were specific organisms, which affected the kidneys electively. He noticed also two important points: first, that although the streptococci produced the nephritis and appeared in the urine, they did not proliferate in the kidneys, and second, that if the nephritis became chronic, the streptococci were apt to disappear from the urine. Mannaberg's investigations and experiments were performed carefully with good modern technic and therefore deserve considerable attention.

A few years later (1894) Pernice and Scagliosi,[7] two Italian investigators, described the acute lesions which they observed in the kidneys of dogs, rabbits and guinea-pigs that had been inoculated either subcutaneously or intravenously with various bacteria (*Bacillus anthracis, Bacillus pyocyaneus, Bacillus prodigiosus and Staphylococcus pyogenes-aureus*), and came to the conclusion that their observations furnished the experimental proof of the existence of a form of glomerulonephritis caused by bacteria. Since inoculations of the toxins of these bacteria had much less effect on the kidneys, they concluded that the bacteria themselves played an important part in the production of the renal lesions. There was nothing specific about these experimental lesions, because they were produced similarly by different types of bacteria, among them even a nonpathogenic organism (*Bacillus prodigiosus*).

In his careful work on acute diffuse nephritis, Councilman[8] mentions the fact that in eighteen out of twenty-eight cases of acute glomerulonephritis, bacterial infection was found either in the kidneys or in other parts of the body. Fourteen of these cases were evidently streptococcus infections, and in eleven of them there was present endocarditis and general septicemia. Councilman states that bacteriologic examination did not reveal anything suggestive in his cases of subacute and chronic glomerulonephritis.

It is to be regretted that Asch's[9] interesting monograph on the influence of bacterial toxins on the kidneys is not accompanied by illustrations, because he seems to have obtained some remarkable results by the injection of dead pure cultures of bacteria into the abdominal aorta near the openings of the renal arteries. He introduced a catheter into the abdominal aorta from below through the femoral artery with the idea of injecting the bacteria directly into the kidneys by way of the renal arteries. He worked largely with organisms of the colon group.

The same idea has recently been utilized by Winternitz and Quinby[10] of Johns Hopkins, who have injected living cultures of *Bacillus bronchisepticus* directly into the renal artery of dogs with the following results: Three groups of experiments were distinguished: (1) those in which no demonstrable general infection occurs; the kidney, however, shows immediate and acute inflammatory lesions which rapidly subside and result in focal scars associated with intermittent albuminuria and cylindruria; (2) those which die acutely with fulminating renal lesion and an acute general infection; (3) those in which there was definite evidence of general infection as well as renal involvement. The first (the general infection) subsided, while the kidney changes progressed and led rapidly to functional impairment to such an extent that the organ was unable to maintain its efficiency after the other kidney had been removed. As shown in the illustrations which accompany the article, the lesions are those of acute, subacute and chronic glomerulonephritis with congestion and enlargement of the kidney in the acute cases and fibrosis and shrinkage in the chronic cases. The advantage in working on one kidney in this way is that one may produce severe lesions without necessarily killing the animal, and may then test the functional capacity of the injured kidney after it has reached the chronic stage, by removing the healthy kidney.

That it is not necessary, however, to inject the bacteria into the arterial blood stream in order to obtain the characteristic lesions in the glomeruli had already been shown by Le Count and Jackson, in 1914. These investigators injected rabbits intravenously with streptococci, and, as their photomicrographs show, produced very characteristic acute lesions in the glomeruli of the kidneys of some of their animals. Their results have been confirmed and amplified in our own laboratory.

Dr. E. W. Smith, under my direction, made repeated intravenous injections in rabbits of streptococci obtained from various sources, in order to study the more chronic changes which might arise in the various organs of these animals. Among forty-eight rabbits, fourteen developed renal lesions, and in seven of them the lesions were well marked and extensive. These seven rabbits lived from thirty-two to 142 days. That certain streptococci seem to have a fairly definite affinity for the kidneys seems to be shown by the fact that two pairs of these rabbits had been treated with the same streptococcus, one pair with a nonhemolytic diplostreptococcus from the tonsils of a case of acute duodenal ulcer, and another pair with a similar organism from an acute gastric ulcer. That this affinity, however, is not very strong is shown by the fact that the lesions in the other three cases were due to different streptococci, and that in other rabbits the same streptococci did not produce any renal lesions. None of the streptococci which caused severe renal lesions in the rabbits were obtained from cases of human nephritis, although we used several such in the experiments. The lesions produced in the glomeruli were very characteristic of acute and subacute glomerulitis, as shown by the accompanying illustrations. The lesions were quite diffuse, so much so that in some of the specimens the great majority of the glomeruli were involved. The tubules contained blood and casts. The epithelium exhibited granular and hydropic, more rarely fatty degeneration. Some of the rabbits presented also well marked focal lesions in the interstitial tissue which, however, were probably due to spontaneous nephritis. Otherwise a moderate round-cell infiltration about the blood vessels was all that could be observed even in the animal which lived 142 days and received eleven inoculations. Three of the seven animals had developed endocarditis, and in three others the condition in the kidneys was associated with amyloid degeneration which is apt to follow repeated intravenous injections of all sorts of bacteria. The arteries in the kidneys and elsewhere were normal in all cases.

These experimental results obtained by us and others seem to prove that the suggestion made by me some years ago on the basis of my findings on human material, that the glomerular lesions in glomerulonephritis are probably embolic and due to the rapid lysis of the bacteria within the vascular loops of the glomeruli, is probably true. The type of bacteria concerned does not seem to be of much importance, provided they possess certain endotoxins which become liberated on lysis. Asch's experiments seem to show that the same results may be obtained with dead organisms as with living bacteria. In the human being we have reason to believe that streptococci, colon bacilli, influenza bacilli and probably other bacteria may act in this way, although streptococci seem to be by far the most common organisms concerned in the causation of human nephritis.

The definite knowledge of the importance of streptococcic infections in acute and subacute glomerulonephritis and much of our modern knowledge on nephritis we owe to Löhlein's[11] careful anatomic and clinical investigations. His observations have been abundantly confirmed since, and are thoroughly accepted in Volhardt and Fahr's[12] important monograph on nephritis. It has also been gradually recognized that the most dangerous forms of nephritis are those associated with streptococcic infections of the tonsil, in which cases the persistence and recrudescences of the renal disease are probably due to the persistence of a septic focus in these organs. Similar results naturally may follow when there is a persistent septic focus elsewhere, and especially when the bacteremia is aggravated by septic endocarditis; but the latter is by no means necessary. I have been suspicious from the beginning of my investigations that chronic nephritis might also be due to such continued septic processes, and I believe that a careful clinical and anatomic study of such cases bears out this supposition.

I shall now attempt to sketch briefly the development of the different forms of glomerulonephritis.

I. ACUTE GLOMERULONEPHRITIS

The condition is usually due to some septic infection, preferably with streptococci arising in the tonsils or elsewhere. In the gross the kidneys are intensely congested, full of petechial hemorrhages, swollen and often quite edematous, so that they may be considerably enlarged. The capsule is tense and peels off readily. The glomeruli are intensely inflamed, permitting the escape of albumin, blood and leukocytes into the capsular space and the tubules. The connective tissue is in a state of inflammatory edema and is also full of leukocytes. The epithelium of the tubules is more or less degenerated, and these are filled with casts. The urine is usually scanty, but sometimes increased in quantity, and is naturally loaded with albumin. It is full of casts and leukocytes and sometimes contains blood in sufficient quantity to be easily seen with the naked eye, while at other times the amount is so slight that it has to be searched for with the microscope. Sometimes there is complete anuria. A bacteriologic examination of the sediment, when obtained with proper precautions, often reveals the causative agent. Often there is injury to the capillary endothelium not only in the kidneys but elsewhere, and we then observe general edema. Unfortunately, this general edema is not well developed in all cases, and there is only a slight puffiness of the face, or even this may be missing. In the absence of general edema, the condition is apt to be overlooked, especially if the primary infection (the tonsillitis, for instance) is not very severe, and the patient may never consult a physician. The disease is especially common in children, and urinalysis should never be neglected in any case that seems at all suspicious, especially when the patients do not recover promptly and completely. A "generally run down" condition and continued anemia are important signs. This early stage apparently is the only one in which the disease may be cured by proper treatment of the septic focus, rest in bed and proper diet. Therefore, it certainly is better to examine 100 or even 1,000 urines unnecessarily than to miss one case. Unless the original septic infection kills the patient or the infection heals completely and the patient recovers, a subacute condition is apt gradually to develop.

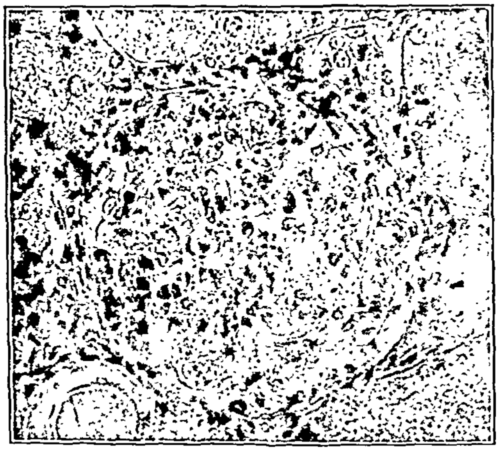

Fig. 1.—Acute glomerulonephritis in a rabbit that had received eleven intravenous injections of a pure culture of a long-chained hemolytic streptococcus obtained from the pleural exudate in a case of carcinoma. Glomerulus congested and infiltrated with leukocytes.

II. SUBACUTE FORM

These cases, however, often develop insidiously without preliminary acute attack, so that when symptoms arise it is impossible to ascertain the date of onset. The kidneys become even more congested and swollen, and the hemorrhages continue. The necrotic spots in the diseased glomeruli and the coagulated exudate in them gradually become replaced by cellular connective tissue, which eventually destroys the glomeruli completely and converts them into an inert mass of fibrous connective tissue. At the same time the inflamed connective tissue between the tubules begins to proliferate. In the later stages, when the connective tissue becomes more massive, evidences of shrinkage may make their appearance. The tubules still contain blood, leukocytes and casts. The epithelium usually exhibits very severe degenerative processes. In some of the cases the blood vessels in the kidneys begin to develop serious lesions which are especially well marked in the arterioles in the vicinity of the diseased glomeruli. They consist in a lateral thrombosis evidently due to injury to the endothelial lining, which process eventually may completely close these small arteries. Eventually organization follows, and a fibrous thickening of the walls of the small blood vessels results. The larger arteries may also be the site of a beginning fibrous thickening of the intima. The large veins in such cases may be entirely occluded by massive thrombi. The urine continues full of albumin, casts and usually leukocytes. Although the hemorrhages persist in the kidneys, the blood does not seem to be carried out so readily, but it can usually be found by repeated microscopic study of the sediment. While at first more or less scanty, the urine in the later stages may become thin and plentiful. Bacteria are more rarely found in the sediment except in early cases. There is usually more or less general edema, although in this form also edema may be missing. Headache, nausea and vomiting make their appearance, and there may be typical convulsions. The anemia commonly is severe and progressive. Neuritis optica with retinal hemorrhage may be observed, and in the later stages the blood pressure climbs up to from 160 to 180, even to 200 and more. This rise of pressure is possibly due to the irritative effect of the same substance or substances which cause the damage to the endothelium of the blood vessels, the irritation causing an increased tonus in the arterioles all over the body which forces up the general blood pressure. The rise of pressure certainly precedes any noticeable general anatomic change in the small arteries, and may persist for long periods of time without being followed by any such change. Whether or not the irritation is to be followed by anatomic changes appears to be purely accidental. It is interesting to note that with these exceedingly severe lesions in the kidneys the phenolsulphonephthalein excretion still may be fair (from 25 to 30 per cent. in two hours), in spite of the fact that the blood urea may go up to 100 mg. and more. These cases last for months and years with exacerbations and remissions. Sometimes the patients are fairly well for a long time and the condition is discovered only accidentally, or in the last stages, when severe symptoms begin to arise. The patients die of their septic condition, or more commonly of asthenia or uremia.

III. CHRONIC FORM

It is naturally impossible to draw sharply the dividing line between this form and the preceding one either clinically or anatomically. In this group are the largest number of cases. Since the publication of my last papers[13] on this subject, I have been able to find seventeen new cases of true nephritis among about 400 necropsies. One of these was an acute one following a streptococcic peritonitis after confinement, of two months' duration. Four were of the subacute type. One of these was caused by a streptococcic osteomyelitis of the sternum of seven months' duration, and three followed tonsillitis. The remaining twelve were chronic cases. In four of the latter the history and the examination were incomplete, usually because the patients entered the hospital in a moribund condition, or because a complete necropsy was not permitted. In the remaining eight there was either a definite history of severe, often repeated attacks of tonsillitis, with or without rheumatic symptoms, or a very characteristic condition of the tonsils was discovered at necropsy, which to me appears to be of great interest.

The tonsils in these cases were not enlarged; in fact, usually they were more or less shrunken. In several of these cases they were carefully examined by the clinicians and pronounced to be normal or practically so. At necropsy one finds them retracted behind the pillars of the fauces. The surface is smooth, more or less white and cicatrized, and the openings into the crypts and the supratonsillar fossa are much narrowed, often practically obliterated. When one squeezes these tonsils, grumose material and pus, often in large quantity, squirts through the narrow openings from the dilated pockets behind. In the pus one finds great numbers of diplostreptococci either in pure culture or mixed with other bacteria. The supratonsillar fossa especially is usually very much distended and full of purulent material, and its walls may be more or less necrotic, although in sections of such tonsils the epithelial lining of the crypts may be entirely intact. Such sections usually show also heavy bands of old scar tissue throughout the tonsils, the contraction of which caused the partial occlusion of the orifices of the crypts. These old "pus bags" probably keep the process in the kidney going by more or less intermittent activity, and I wish to emphasize again that this condition may be present without any knowledge on the part of the patient, and that it is difficult to discover clinically. Why such a condition, which undoubtedly is quite common in persons not afflicted with nephritis, should cause chronic progressive nephritis in some cases, chronic rheumatism in others, or both, or sometimes no general trouble whatever, is quite as difficult to explain as the experimental observation that if one injects rabbits intravenously with various strains of streptococci one sometimes observes a severe reaction on the part of the kidneys and sometimes none at all, nor does one always get the same effect with the same strain of bacteria.

The development of these chronic cases is usually very insidious. The course extends over many years. The original lesion in many of them undoubtedly dates back to childhood. The existence of the condition is often not noticed by the patient until quite late because the symptoms may not be pronounced and the patients are accustomed to them. The clinical history usually begins only a few months or at best a few years before death, when there is often quite a sudden change for the worse from a condition of apparently continued well-being. The kidneys at necropsy are always much shrunken, either smooth or granular or sometimes more coarsely lobulated. Whether they ever were swollen considerably at any stage of development of the disease appears to me doubtful. They show the characteristic microscopic picture of an advanced renal sclerosis with small remnants of badly degenerated or sometimes fairly intact hypertrophic kidney tissue. Even in this late stage, subacute lesions indicating more recent recrudescences may still be present. The remnants of renal tissue are often so exceedingly small that one never gets over wondering how the individuals have been able to exist so long before they finally die of the disease. The arteries in the kidneys are usually severely affected, but there are striking exceptions to this rule. There may be a good deal of general arteriosclerosis, but this also is by no means constant. The blood pressure is usually high (from 200 to 250) and there is a marked hypertrophy of the heart, but as I have pointed out before, there seems to be a group of cases in which extreme destruction of the kidneys is observed without hypertension or cardiac hypertrophy.

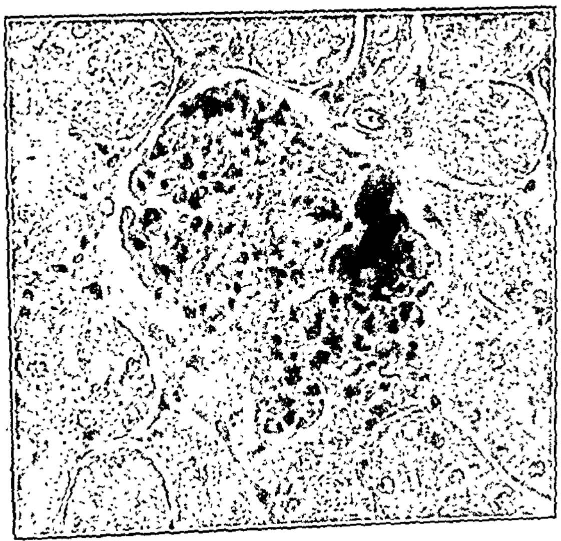

Fig. 2.—Recent glomerular lesion in a rabbit that had received seven intravenous injections of a pure culture of a nonhemolytic diplostreptococcus from the heart blood of a patient with acute leukemia. One of the loops contains a mass of micrococci, another is filled with a hyaline thrombus.

When these patients come to the hospital the urinary changes are usually well marked. While they are still fairly well, they usually have polyuria and hyposthenuria. Toward the end the amount of urine naturally decreases. At this stage there is always considerable albumin in the urine. Casts may be plentiful or appear in showers; occasionally there is a slight admixture of blood or leukocytes. The phenolsulphonephthalein secretion in the later stages is always diminished, sometimes practically entirely suppressed; toward the end the blood urea goes up with the appearance of true uremia and often reaches very high figures. Edema may be a prominent symptom, but there are the well known "dry cases." The first symptom which in many of these cases drives the patient to the physician is interference with the eyesight due to albuminuric retinitis. The anemia is often well marked and sometimes very severe. The temperature is often quite fluctuating, frequently subnormal. The pulse is usually high and the pulse rate varies greatly. The patients most commonly die in uremia. Sometimes the condition is aggravated, or sudden death is produced, by lesions of the brain, due either to vascular obstruction or to hemorrhage.

[13] Ophüls, William: Nephritis: A New Series of Cases with Review of Recent Literature, The Journal A. M. A., Nov. 13, 1915, p. 1719; The Pathology of Nephritis as Illustrated by Thirty-Two Consecutive Cases, Stanford University, 1916.

The patients included in this last group vary so much in their rate of development, in the gross and microscopic appearance of the kidneys and in their symptomatology, that one can readily understand why both from an anatomic and from a clinical point of view numerous efforts have been made to subdivide this group into subgroups, according to whether, anatomically, the disease of the blood vessels in the kidneys or elsewhere plays a prominent rôle, or whether, clinically, the signs of cardiovascular disturbance predominate over those of renal origin, or vice versa. So far as I can see, and I have now studied about thirty cases carefully, both from the clinical and from the anatomic point of view, such a subdivision does not seem feasible. I acknowledge that the number is too small to arrive at any final conclusion. I wish to emphasize, however, that from this group have been rigidly excluded all cases in which anatomically the disease of the kidney was not well marked and extensive, which procedure, so far as the clinical histories go, has eliminated all the ordinary cardiovascular cases. I believe that the chronic cases collected by me correspond to Group 3 of Christian's[14] most recent clinical classification, and probably take in part of his Group 2.

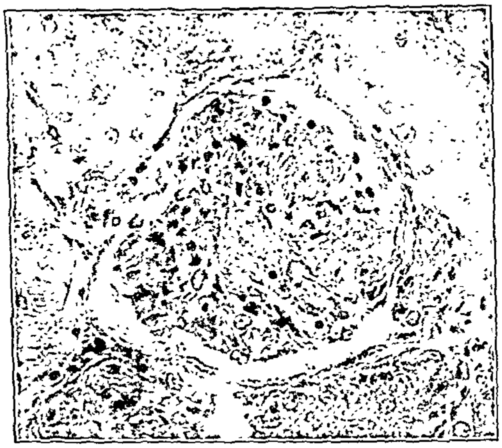

Fig. 3.—Later glomerular lesion in another glomerulus of the same rabbit, showing hyaline necrosis of a large part of the glomerulus and beginning adhesion to capsule.

SUMMARY

1. There is a well defined disease of the kidneys caused by general sepsis arising from some infected focus and often made progressive by the persistence of such a focus.

2. Since the glomeruli in this disease show the most *characteristic and constant* lesions, we may speak of it as glomerulonephritis, and as the lesions are so distinctly of an inflammatory character, as true nephritis.

3. The disease occurs in three forms: the acute, the subacute and the chronic type.

4. The characteristic glomerular lesions may be reproduced in animals by injection of bacteria into the blood stream.

5. The majority of cases in man are due to streptococci, but other bacteria may cause similar lesions in the kidneys and elsewhere.

6. Many of the chronic cases seem to be caused by a peculiar form of chronic suppurative tonsillitis due to diplostreptococcic infection.

JUXTA-ARTICULAR BONE LESIONS OF THE HIP *

HENRY LING TAYLOR, M.D.
Fellow of the American College of Surgeons
AND
GEORGE BARRIE, M.D.
Fellow of the American College of Surgeons
NEW YORK

The beginner in bone surgery is apt to think of the diagnosis of disease of the hip joint as a simple matter, but longer experience will convince him of his error. As pointed out by Gibney in 1884,[1] the diseases of the hip are many, owing to different infections and pathologic processes, and may be located in the joint, in the bone adjacent to it, or in the soft parts. Many affections which were formerly classed as hip disease or tuberculosis of the hip, especially since the wide use of the roentgen ray in diagnosis, have come to be recognized as distinct conditions. Such conditions, now classed as separate affections, are coxa vara and slipped epiphysis, lesions fairly well known and not difficult to diagnose. More recently, osteochondritis of the hip, Perthes' disease, or quiet hip disease (Taylor[2]), a perfectly benign affection, has been studied and separated from tuberculosis of the hip. While studying Perthes' disease, characterized by its mild symptoms and course, our attention was called from time to time to lesions in the neck of the femur or in the trochanteric region, benign in character and causing mild symptoms extending over a considerable period. These cases, usually brought to the surgeon on account of a persistent lameness with little pain or stiffness, could not be distinguished clinically from early osteochondritis; but the roentgen ray revealed instead of a flat and irregular epiphysis, a perfectly normal head and epiphysis with a spot of osteolysis (light spot) in the neck or trochanteric region.

These cases are often due to the process known as hemorrhagic osteomyelitis (Barrie[3]), *which never* results in pus formation. In another class of cases, *localized infectious foci with pus formation are found,* the so-called "bone abscess," which may result from the acute invasion of any pus-forming organism, or may arise from the lighting up of a local process in an old osteomyelitis. Several examples of roentgenographic bone spots, both of infectious and of noninfectious origin, will be given in this paper. Similar processes may occur about the acetabulum, but these will not be considered here, nor will malignant or benign neoplasms, tuberculous and syphilitic disease, or other rarer conditions which may produce local bone lesions in the neck and trochanteric regions.

It is well to know that lesions of soft parts adjacent to the hip, such as abscess of the soft parts, bursitis, and hematoma, may affect the function of the hip joint without affecting the bone, or even the synovial membrane. Acute and transitory conditions simulating an acute synovitis may result from strain or mild infections and pass away after a few weeks, leaving no impairment; but our discussion will be confined to the two classes of local bone lesions mentioned above, when occurring near the hip. They also occur near the knee and ankle and in the upper extremity, and may rarely be multiple; it is hoped to describe these conditions in later papers.

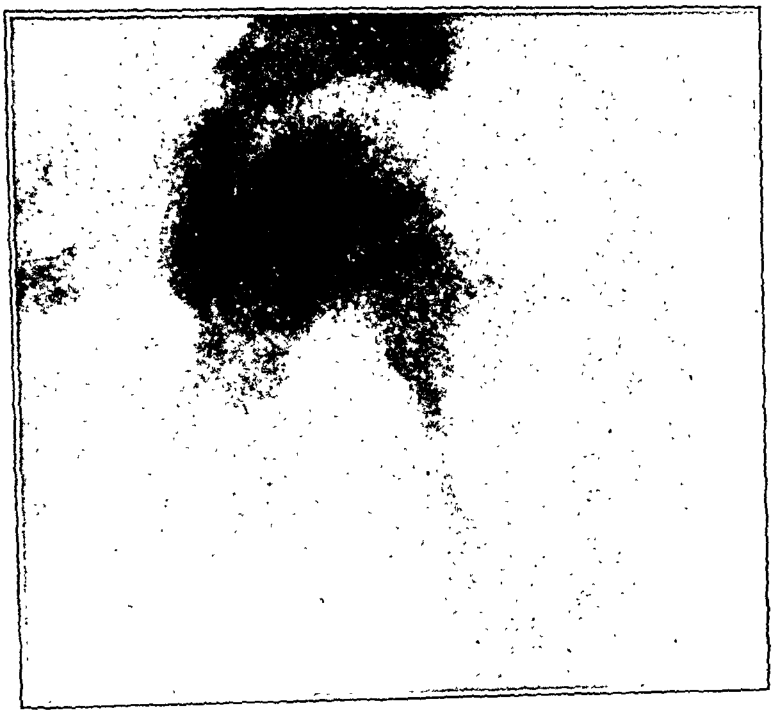

Fig. 1 (Case 1).—Hemorrhagic osteomyelitis in a girl, aged 7; there were mild symptoms for four weeks.

The one common symptom of the various hip conditions, at least when somewhat advanced, is lameness, and when a child suffering with lameness of longer or shorter duration is brought to the physician he should never rest satisfied until a positive diagnosis is made, no matter how mild the symptoms. This means that, besides a thorough clinical examination, the roentgen ray should be used in every doubtful case. Repeatedly we have seen, in cases of mild lameness with few or no other symptoms, the diagnosis established at once by the presence of a light spot on the roentgen plate.

Certain light spots are due to focal osteolysis caused by hemorrhagic osteomyelitis (Barrie). The process may exist without causing any symptoms, as in a case (Case 3) recently observed, in which a roentgenogram of the hips was made, simply because the boy had a spot in the lower end of the opposite femur. In several of these cases, the lesion was of large size and in an advanced stage, though the lameness had lasted only a few weeks. In many instances there is a history of a near or remote fall or injury. Usually the lesion is as large as a dime or a nickel before the advice of a bone surgeon is sought. By this time there is a little wasting of the thigh and leg muscles, and a little pain about the hip or knee. As the lesion becomes larger, the lameness and pain increase, the activity of the child is diminished, and his condition is not quite up to par, though often the general health is entirely unaffected; there is no fever. In a few cases there are sudden exacerbations with severe pain and inability to walk. The process may go on until the entire area at the base of the neck and the trochanter is involved, leaving only a cortex of egg shell thinness.

In two of our patients (Cases 8 and 9), the femur broke on slight violence, in both instances healing kindly under splinting. These cases are usually called tuberculosis of the hip and treated as such (overtreated), even by experienced diagnosticians; they are occasionally called sarcoma.

Among our cases there are several with spontaneous healing, with fibrosis or ossification and complete restoration of function, under general or symptomatic treatment and regulation of activity, and sometimes without treatment. In other cases, the cavity becomes larger with or without expansion of the bone cortex, and sometimes perforation occurs. A piece of the wall may come away as a flake, but there is no real sequestrum, no involucrum, and no pus formation. In these advancing cases evacuation of the focus with moderate curettage of the cavity, and in the larger ones the introduction of autogenous bone chips, give uniformly good results. The cavity becomes obliterated and usually reossified. When the cavity is opened it is found filled with reddish or grayish granulations, much like spleen pulp, or by a yellowish or grayish mass like custard, or by mottled fibrous material, or again by a straw-colored serum. The cavity may or may not have trabeculae or a lining membrane; it is sometimes multilocular. The mild curettage and the introduction of bone chips stimulate osteogenesis, and the result is usually perfect or nearly perfect restitution of structure and function.

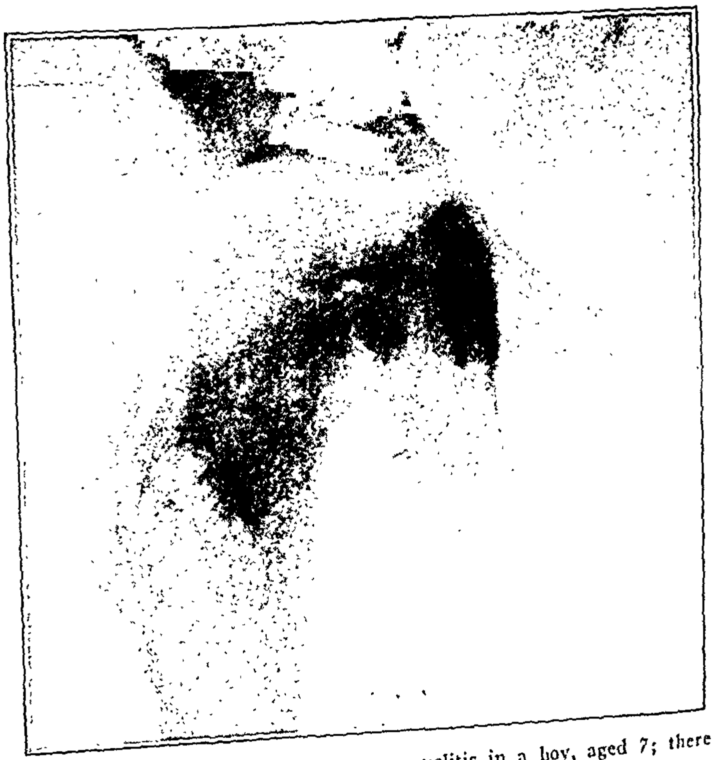

Fig. 2 (Case 3).—Hemorrhagic osteomyelitis in a boy, aged 7; there were no symptoms.

General hygienic management and a reasonable curtailment of activity, and short periods of splinting and recumbency when indicated, are effective in the milder cases without operation. The lesion and lameness may last for several years.

THE PATHOLOGIC PICTURE IN HEMORRHAGIC OSTEOMYELITIS (BARRIE)

In about 75 per cent. of our series of bone lesions termed hemorrhagic osteomyelitis, a definite history of initial trauma or injury has been obtained. These injuries, not necessarily severe, produce numerous minute fractures of some of the delicate bone trabeculae that compose a great part of the osseous structure. In turn, there follows a disturbance of the normal anatomic circulatory apparatus. As the venous supply is here composed of vessels that are without any muscular coat, the lack of support of trabecular framework causes dilatation of the lumen of the vessels, varicosities, venous stasis, and rupture with effusion. The size of the initial lesion, through solution of continuity, may now be increased by pressure from within, exerted against the very delicate normal surrounding osseous structure, causing inhibition of nutrition, rarefaction and further destruction of the bone trabeculae, with repetition of circulatory disturbance noted above.

Efforts at regeneration and restoration are brought about in the formation of highly vascular granulation tissue. As no virulent or infective process is here involved, the injury being due apparently to mechanical insult to tissues that are sterile, and as there is no great massive destruction of structure, the inflammatory process is of a mild type.

It is a well known fact that a low grade inflammation producing granulation tissue always causes proliferation beyond its given need. In these bone lesions it is found that, when the bony defect is filled, several changes take place.

1. If the chemotactic properties in the blood of the individual cause a sufficient stimulant reaction, the vascular granulations are converted into final osseous structure, and full anatomic restoration and architectural arrangement of tissues result.

2. The host may possess the power to produce a metaplasia in the lesion by converting the granulation tissue that fills the bony defect into fibrous structure only. In this event the further progress of the lesion is stayed. It is Nature's effort at cure. While the stimulant reaction of the blood is not enough to give normal restoration of structure, it marks the end of any further progress in the lesion. The fibrous metaplasia causes contraction and retraction of the former exuberant vascular granulations. This stage of the process gives a picture of a fibrocystic osteomyelitis. Absorption or disappearance of all connective tissue apparently sometimes occurs, leaving a bone cavity without any lining membrane, but with bony walls rather more dense than the adjoining outlying tissue. Such a cavity may contain sanguineous fluid only or, what is perhaps more frequently observed, a thin straw-colored fluid. The fluid is sterile, and pus is never present.

3. If conditions pertaining to the host are hostile to either of the foregoing reactions, we observe little or no change in the granulation tissue occupying the bony defect. The attempts at regeneration are feeble, apart from the proliferation of granulation tissue. A vicious circle is thus established. Overproduction of granulations causes pressure on the osseous structure that it is apparently unable to withstand. Nutritional inhibition of the framework produces rarefaction and further bone destruction, followed by circulatory disturbances and changes. This stage of the lesion, when it attains any size, is quite commonly wrongly termed, clinically and roentgenologically, "giant cell sarcoma." The histopathologic picture presented in this stage of the lesion is marked particularly by the presence of numerous multinucleated giant cells that are apparently performing their scavenger function of removal of débris. They are practically never present in the second phase of the lesion.

BONE ABSCESS

An infective bone spot may result from acute pneumococcus, staphylococcus, or other acute infection, when the invasion may be sudden, with fever, pain and constitutional symptoms. The symptoms are much more severe and the disability greater than in the noninfective bone lesions. The acute stage may pass over into a chronic stage, when the symptoms are moderate, more like those of a beginning hip tuberculosis, for which it is usually mistaken. Some cases begin without any acute symptoms and generally acquire a slight lameness which may persist for a considerable time, and cannot be distinguished clinically from either hemorrhagic osteomyelitis or beginning Perthes' disease. The roentgenogram will help, but is not always decisive as between a benign bone spot and a bone abscess. If the cavity at operation is filled with pus, which, however, may be sterile, the lesion is a bone abscess.

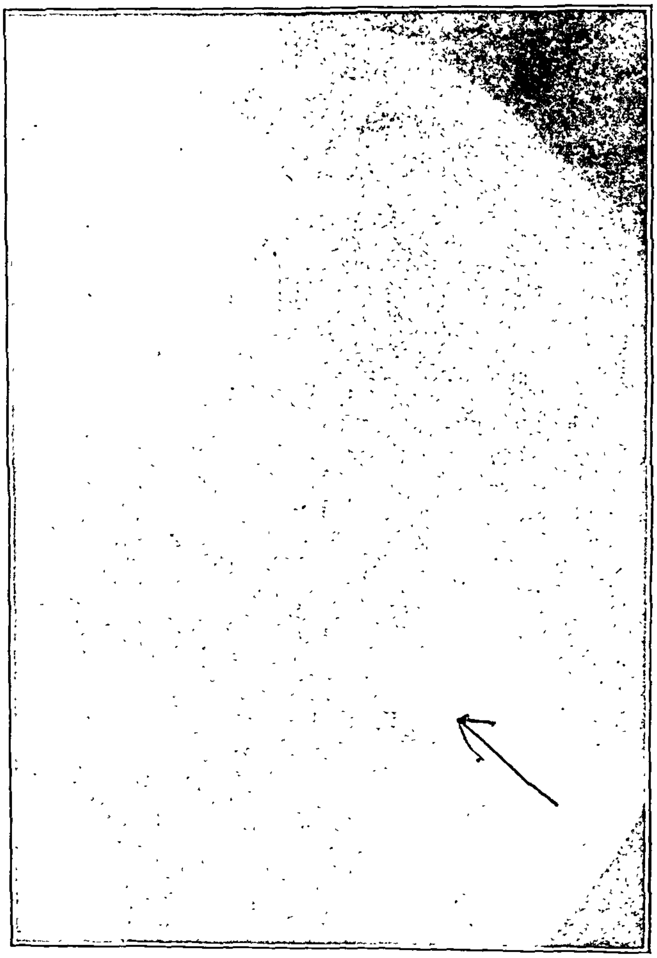

Fig. 3 (Case 4).—Hemorrhagic osteomyelitis in a boy, aged 17; there were mild symptoms for one year.

One of our patients (Case 13) was treated for several years for hip tuberculosis, when the bone abscess finally discharged itself in the trochanteric region, with later ossification of the spot and complete restoration of function. These lesions, when extrinsic and virulent enough, cause hip joint symptoms by secondary infection or through extra-articular soreness.

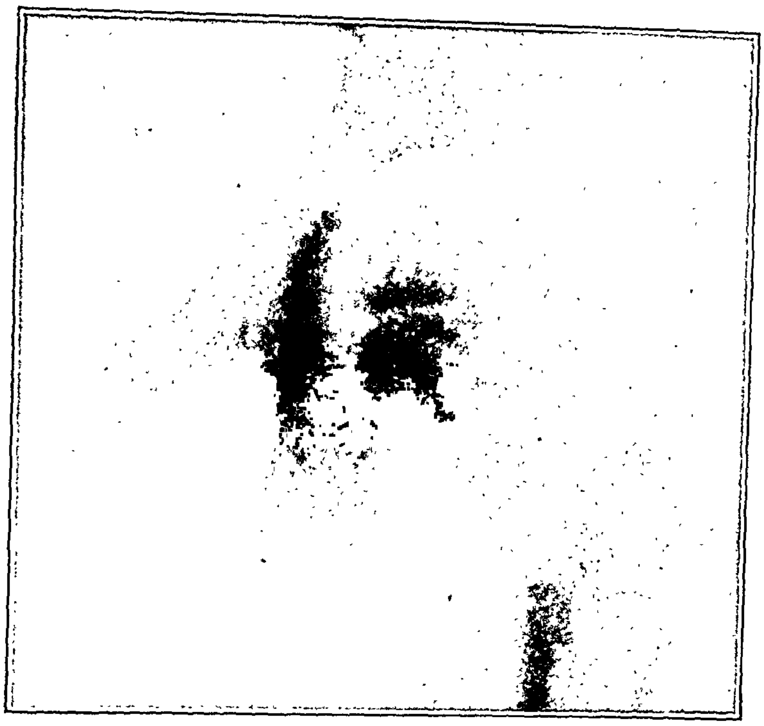

Fig. 4 (Case 5).—Hemorrhagic osteomyelitis in a girl, aged 7; there were symptoms for two weeks.

In another class of cases, an old osteomyelitis of the upper end of the femoral shaft or the trochanteric region may, after years of quiescence, light up into a local focus, showing a light spot on the plate (Cases 17 and 18). This is because bone once infected may become quiescent, but probably carries infective organisms ever after. They may light up locally after trauma or impaired nutrition, or without any visible cause, not becoming infected throughout but only causing one or more local bone abscesses.

The invariable treatment is to open the bone and evacuate, scrape out and disinfect the abscess. Pus is always found. The cavity should be wiped out with tincture of iodin, drained, and allowed to granulate from the bottom. Such cases do not always heal at once, but many heal in a short time, and most of them do so after a few weeks or months, while the pain and disability are quickly relieved.

Similar treatment is also suitable for tuberculosis confined to the trochanter or base of the neck, and such timely measures will often prevent an extension of the process to the joint.

COMMENTS ON ROENTGENOGRAPHIC APPEARANCES (BARRIE)

The roentgen-ray diagnosis of hemorrhagic osteomyelitis is not, as a rule, difficult to make. The plate shows a light spot with smooth outlines and no sclerosis; it may appear to be reticulated or multilocular. It is, however, frequently impossible to state positively, even with the combined clinical and roentgen-ray pictures, the exact stage which the lesion presents, that is, whether it retains its primitive form of a highly vascular granulation tissue mass (solid type so-called giant-cell sarcoma); whether the lesion is fibrocystic in character (metaplastic stage), or whether the contents of the localized area of osteolysis or bone disintegration are wholly fluid (so-called bone cyst). Our experience does not coincide with that of some roentgenologists, who state that they are able to differentiate between the roentgen-ray appearance of the solid and fluid lesions by the presence of trabecular division or septa. We have found identical roentgen-ray shadows in all stages of this lesion.

The roentgenographic picture in bone, exhibited by tuberculosis, syphilis, the acute infections, and benign and malignant neoplasms may readily be differentiated from the type lesions coming under the classification "chronic hemorrhagic osteomyelitis."

A conclusive and positive diagnosis regarding the exact type and stage of the lesion may be made only during operative interference. The light spot on the plate due to a bone abscess may be of irregular outline, may contain a sequestrum, or may be surrounded by sclerosed bone, but roentgenologically it is sometimes difficult to differentiate between a hemorrhagic osteomyelitis and a circumscribed medullary bone abscess that does not contain any sequestrum. The pus in such lesions is usually sterile.

Most of the cases on which the preceding study is founded were observed in the remarkably interesting material which has been at our disposal at the Hospital for Ruptured and Crippled, New York. Abstracts of the histories follow. In all, the descriptions of the lesions are founded on roentgen-ray plates.

CASES OF HEMORRHAGIC OSTEOMYELITIS OF NECK AND TROCHANTERIC REGION[4]

Case 1.—A girl, aged 7, Jan. 28, 1917, had a heart shaped light spot 1¼ by 2 inches in the left trochanteric region. Her health was good but she had stigmata of previous rickets. The patient slipped, four weeks before; this accident was followed by lameness and pain in hip and knee. At present all hip motions are painless and free; she has a moderate limp, and also slight atrophy.

Case 2.—A boy, aged 3, Sept. 24, 1914, had a light spot the size of a robin's egg in the left trochanteric region. There had been no injury; twelve days before he had moderate pain in the knee and could not walk. The pain was soon relieved by plaster-of-Paris spicas, which he wore eighteen months.

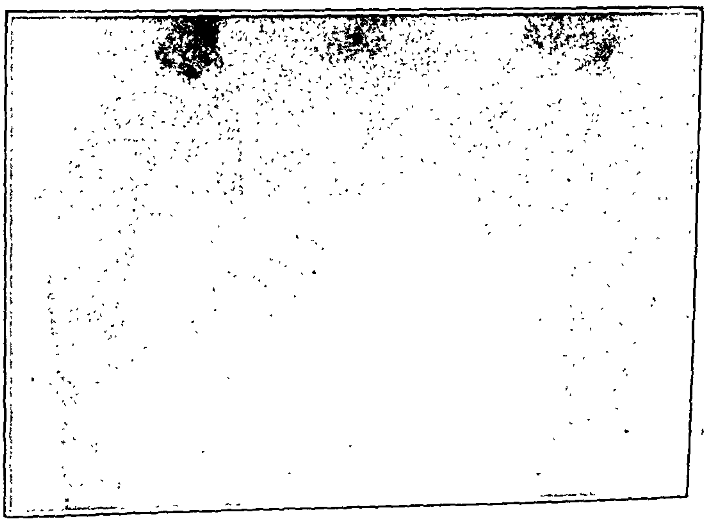

Fig. 5 (Case 8).—Hemorrhagic osteomyelitis in a boy, aged 6; he limped for four weeks. The roentgenogram was taken soon after the fracture through the pathologic area.

Case 3.—A boy, aged 7, April 24, 1917, had a light spot in the left trochanteric region the size of a robin's egg; there were no symptoms. The hip was examined with the roentgen ray for information on account of pain, swelling, and lameness in the right knee, beginning three years before. The patient was treated for tuberculosis of the right knee at

---

[4] Cases 7, 8, 9 and 10 correspond to Cases 11, 12, 13 and 14 in Barrie's[3] paper, "Cancellous Bone Lesions," which gives histories and illustrations.

Neponsit Hospital, and wore plaster-of-Paris splints one and a half years. At present the knee function is perfect; there is no limp and no pain. A roentgenogram of the knee shows an extensive light area from changes due probably to hemorrhagic osteomyelitis. This is the first case of multiple lesions of this character observed.

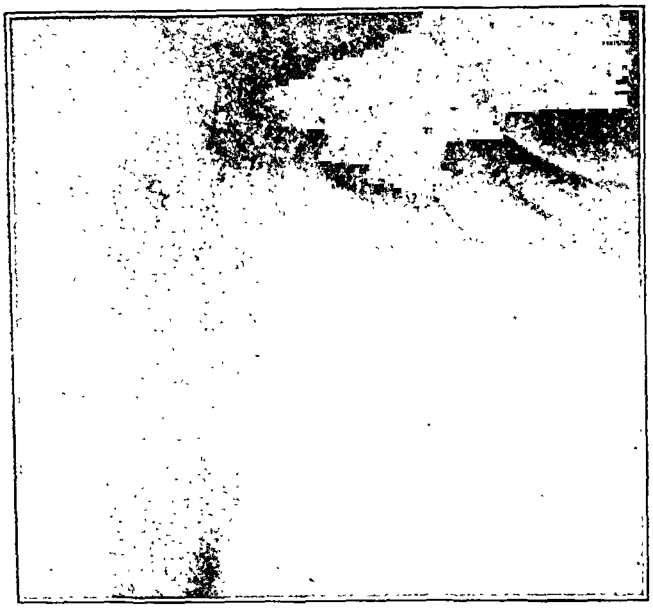

Fig. 6 (Case 12).—Bone abscess, secondary to chronic osteomyelitis of tibia of opposite side, in a girl, aged 9.

CASE 4.—A boy, aged 17, Sept. 14, 1905, had a light spot the size of a lima bean in the region of the left trochanter minor. He had been slightly lame for over a year; he had mild hip-joint symptoms, and was put on crutches and high sole, and hygienic management. A month later a roentgenogram showed an oval light spot the size of a dime near the lower trochanter; the bone of the neck was much thickened.

Feb. 22, 1906, the spot was increasing. The patient was running down, and the hip motions were somewhat limited. The patient was put under ether and the small cavity that was filled with granulations was scraped out. The patient has recovered perfect function of the leg and has remained entirely well.

CASE 5.—A girl, aged 7, Nov. 11, 1916, Dr. Whitman's case, had a multilocular light spot occupying the whole of the right neck, as revealed by a roentgenogram. The symptoms had existed two weeks.

CASE 6.—A boy, aged 11, July 12, 1914, had a light spot in the neck of the right femur. He had been hit by a horse one year before. He had pain in the right hip for six months, which was worse at night; he had limped for two months. A diagnosis of arthritis of the right hip was made.

Oct. 9, 1914, motion of hip was limited; the boy had worn spicas until two weeks before; there was no spasm; roentgenoscopy revealed a spot in the neck the size of a large pea.

March 8, 1915, the focus was curetted by Dr. Barrie. The patient had continued to wear a spica and to get worse. The pathologic report was extreme acute osteitis.

April 11, 1917, the patient was well, with excellent function and no limp. Roentgenoscopy was negative for spot.

CASE 7.—A girl, aged 8, October, 1913, had a light spot in the left neck and in the trochanteric region. The patient fell, bruising the left hip, six months before; she had had pain in the left hip and had limped for the last three months; there were night cries for two months; there was slight atrophy and limitation of motion. Clinical diagnosis was acetabular tuberculosis of the hip. A roentgenogram revealed a light area the size of a pigeon's egg occupying the base of the neck and trochanteric region to the cortex. The Wassermann test was negative. A plaster spica was applied in June, 1914, with increase in the size of the lesion and of stiffness at the joint. Operation was performed by Barrie, July, 1914. Exposure exhibited a hemorrhagic fibrocystic loose edematous mass easily removed and separated with the curet. There was free bleeding from the cavity walls, which had no lining membrane. The naked eye appearance of the lesion was that of the transitional stage of localized hemorrhagic osteomyelitis, in which the solid mass was undergoing fibrocystic changes.

Microscopic examination made from material curetted away revealed a variable histologic appearance. The bone trabeculae exhibited a slight degree of disorganization and the medullary tissue evidence of fibrosis. The principal feature appeared to be the presence of new-formed tissue composed for the most part of medium-sized fibroblastic cells. Here and there a multilobulated nucleus and a rare mitotic figure were seen. A few giant cells of the scavenger foreign body type were observed about the areas of disintegration, together with moderate hemorrhage, scattered foci of pigmented cells, and round cells.

In May, 1917, recent roentgenograms had shown reossification of the cavity. Three months before, the patient walked perfectly and was free from disability of any kind.

CASE 8.—A boy, aged 6, March, 1914, had large light area in the left neck and trochanteric region, as shown by roentgenogram. He had fallen down stairs a year before, bruising the left hip; he limped four weeks; there was no pain; there was tenderness over the trochanter, with slight limitation of motion. Wassermann and von Pirquet tests were negative. A plaster spica was applied. Several weeks later the patient was brought to the hospital unable to walk after a fall. Roentgenoscopy revealed a pathologic fracture through the light area.

June, 1914, operation, by V. P. Gibney, revealed a cavity without lining membrane filled with straw-colored fluid. A plate taken several months later showed union of fracture, filling in of cavity, and considerable reossification.

CASE 9.—A girl, aged 4, May 29, 1914, had a large, light spot in the trochanteric and adjacent regions, as shown by roentgenogram. Eighteen months before, the patient fell out of bed. Four weeks before, the child began to limp; there were no joint symptoms, and measurements were equal, but there was tenderness over trochanter.

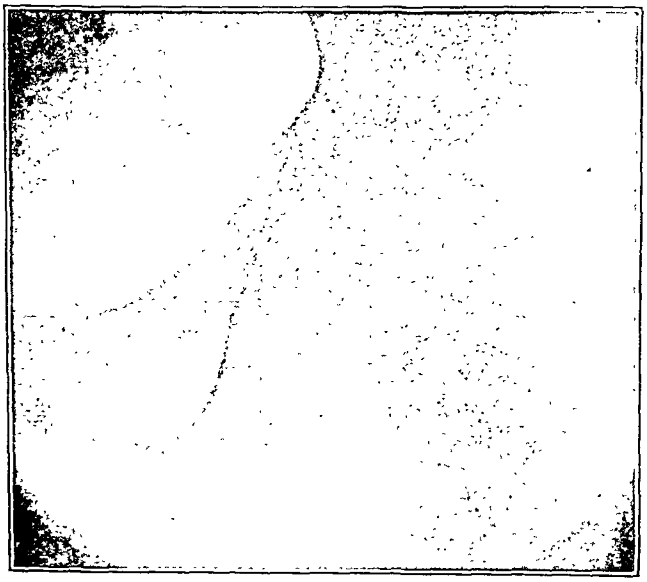

Fig. 7 (Case 13).—Bone abscess in a girl, aged 9; there were symptoms for three years.

Three days later the child tripped and fell and was brought at once to the hospital unable to move the leg. A roentgenogram revealed a fracture below the trochanter through the pathologic area.

CASE 10.—A girl, aged 18, Feb. 28, 1911 (patient of Dr. William Frieder), had multiple light spots in the right trochanteric region, which was enlarged. Six years before the mass had been curetted out, and a pathologic diagnosis of giant-cell sarcoma was made. Several Wassermann tests were negative. This patient was recently seen, ten years or more after the operation. She was in good health and walked well.

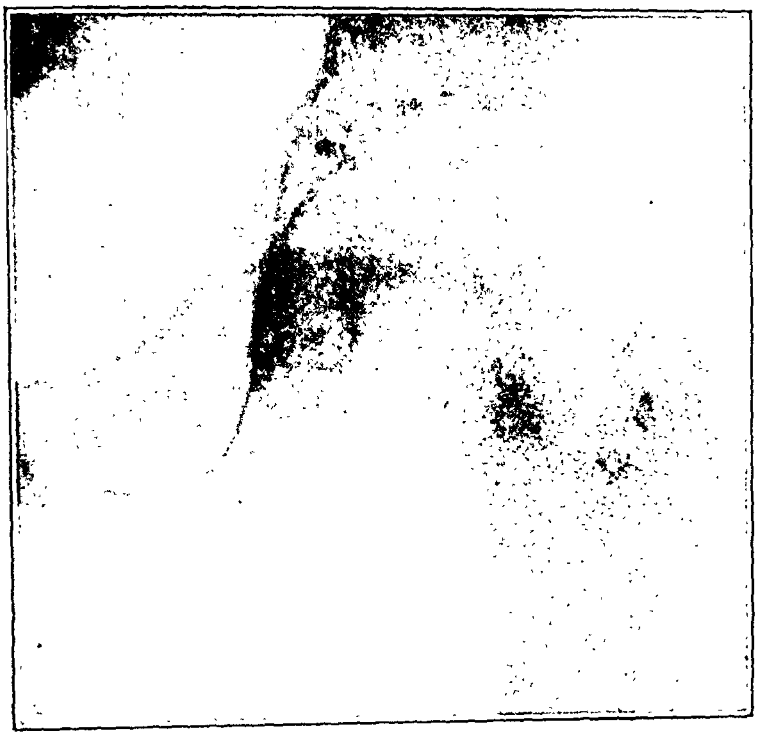

Fig. 8 (Case 13).—Roentgenogram taken one year and eight months later; there was a cure after spontaneous discharge of the abscess.

BONE ABSCESS CASES

Case 11.—A girl, aged 2, Feb. 15, 1915, had large focus at the base of the right neck, with sequestrum, the size of a pea. Limp had been noticed six months before; her general condition was poor; the right leg was one-quarter inch shorter than the left; there was slight limitation of hip motion. The Wassermann test was negative.

Case 12.—A girl, aged 9, April 8, 1916, had a small focus at the middle neck of the left femur. Five years before she had had osteomyelitis of the right tibia with four operations. She had had pain in the knee the last six months; lately there had been swelling in the left adductor region; there was considerable limitation of motion.

April 11, 1916, the neck of the femur was tunneled from below the trochanter by Barrie; sequestrum was removed; the abscess in the adductor region was incised.

Nov. 9, 1916, the sinus was closed, the patient walked easily, with a slight limp.

Case 13.—A girl, aged 6, Oct. 6, 1912, had a bone abscess in the right neck; she had had scarlet fever and pneumonia in 1910; her general condition was poor; there had been discomfort in the knee and night cries for two months. A diagnosis was made of tuberculous hip. She wore spicas for three years. An abscess several inches below the trochanter was opened in July, 1914; closed in December, 1916. A roentgenogram revealed a large light spot in the neck.

March 1, 1917, walking had been without limp or complaint for twenty months; her general condition was good; her legs were equal, hip motion was normal; roentgenograms were now negative for the spot.

Case 14.—A girl, aged 14 months, Oct. 26, 1911, had a bone abscess of the right neck; there were atrophy and pain in the right leg. The first diagnosis was poliomyelitis with history of attack four months before.

May 1, 1912, the child had night cries and was losing flesh; rotation was limited; the diagnosis was changed to tuberculosis of the hip. Soon after the roentgenogram showed a large spot in the neck and atrophy of head. The diagnosis was again changed to bone abscess.

March 5, 1913, the child was plump and rosy; she had almost full hip motion; she still walked lame, with no pain. May, 1917, the patient had been in a home for convalescent cripples for two years.

Case 15.—A boy, aged 9, Aug. 11, 1915, had a bone abscess of the left hip. He had pain in walking and at night. The attack came on suddenly four months before. There was some limitation of motion at the left hip. Roentgenoscopy was negative. The diagnosis was tuberculosis of the hip, and a plaster spica was applied.

Oct. 22, 1915, the thigh was flexed and adducted; two weeks before, the pain suddenly became severe and the patient could not walk; the hip was painful on motion; he was admitted to the hospital; the pain was relieved by traction in bed. A roentgenogram revealed a spot in the inferior lip of the neck, apparently containing a sequestrum.

Feb. 7, 1916, the patient was readmitted for pain and night cries; the abscess had appeared below Poupart's ligament and was incised.

July 14, 1916, the patient was free from pain, and was discharged in fair condition; a short spica was supplied and crutches were used.

Case 16.—A girl, aged 18, Jan. 29, 1916, had a bone abscess of the neck of the left femur. Twelve years before she had an abscess back of the trochanter, which healed in six months; she had had no further trouble until recently; she had had pain in the left thigh, knee and hip. She had no pain or stiffness on moving the hip. A roentgenogram revealed a light spot the size of a dime near the trochanter. Operation was advised and declined. The pain got worse and was considerably relieved by fixation in a spica.

Case 17.—A man, aged 23, Oct. 9, 1916, had chronic osteomyelitis of the upper end of the right femur, with bone abscess near the trochanter. Pain in the right hip and groin to the toes came on slowly five years before; the patient could not get off his chair for five weeks; he did not feel sick; since then he had had similar but milder attacks lasting about a week, every two or three months. Two years before, a sinus appeared 4 inches below the trochanter, which was still discharging. Two weeks before an abscess appeared below the trochanter. The patient's health is good; he is not lame, has no pain, with hip movements free. A roentgenogram shows a spot near the base of the trochanter.

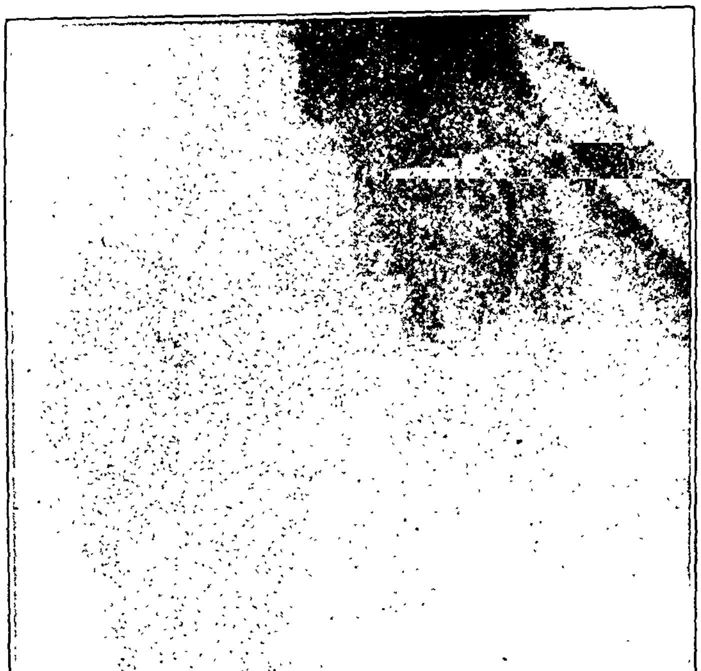

Fig. 9 (Case 16).—Bone abscess in a girl, aged 18; there were symptoms for a few weeks, but she had had abscess twelve years ago.

October 18, curettement of the focus was performed by Taylor. The pathologic report was chronic inflammation and fibrosis.

Case 18.—A man, aged 34, Dec. 4, 1916, had chronic osteomyelitis of the upper third of the right femur, with bone abscess. The patient had osteomyelitis of the upper third of the right femur at the age of 9 years, resulting in several sinuses, which did not entirely heal until eight years later. He was in bed one year at the beginning of the attack. He had been well and free from pain for seventeen years, until a month ago, when he had a dull pain in the upper part of the thigh, growing worse. There is acute tenderness at the outer and posterior aspect of the shaft of the femur below the trochanter and some induration. The leg is in good position with about 10 degrees of motion at the hip. The affected leg is a quarter inch longer than the other. A roentgenogram shows an area of bone induration, with a light spot the size of a pea in the middle.

Dec. 20, 1916, curettement of the focus was performed by Taylor.

March 1, 1917, the pain was relieved at once; the wound healed and the patient walked well.

SUMMARY

Local bone osteolysis may cause a light spot in the neck or trochanteric region on the roentgen plate. This may be due (*a*) to hemorrhagic osteomyelitis, which is a benign process usually running a chronic course with mild symptoms, notably lameness, and frequently ending in recovery, sometimes with and sometimes without an operation. Pus is never present; or (*b*) to a bone abscess with the formation of pus, which may run an insidious course with mild symptoms, or a more acute course with severer symptoms, and if evacuated and drained, usually ends in recovery with good function.

Both classes of cases are often diagnosed as hip tuberculosis, and sometimes as sarcoma. An early correct diagnosis enables the surgeon to simplify the treatment and save the adjacent joint by a timely operation, when its integrity is threatened.

125 West Fifty-Eighth Street—24 East Forty-Eighth Street.

ABSTRACT OF DISCUSSION

Dr. E. D. Oppenheimer, New York: I should like to know which of the patients with these local lesions had also lesions in other bones; also what is the relation between this disease and the general metaplastic osteitis described by von Recklinghausen. Does the pathologic picture resemble that of the other disease?

Dr. Arthur Steindler, Iowa City, Iowa: My understanding is that it is now being recognized that osteitis deformans and the osteitis fibrosa of von Recklinghausen are not entirely different diseases. The osteitis deformans (Paget) is a generalized form of the other. From the roentgenogram I had the impression that the cysts had developed on the basis of an old osteitis fibrosa. They had a hemorrhagic content. I should like to know the differential point between that form and the cases that we diagnose as the osteitis fibrosa of von Recklinghausen.

Dr. Henry Ling Taylor, New York: I would call atten-to the importance of distinguishing infective and noninfective bone spots near the hip from hip tuberculosis, and to their more favorable prognosis under proper management. Dr. Barrie will answer the pathologic question.

Dr. George Barrie, New York: The lesions of hemorrhagic osteomyelitis are single lesions; that is, they have been single in the cases observed, numbering about forty. Three fourths of our patients have given a history of initial trauma. I think probably 75 per cent. of the lesions that start as a hemorrhagic osteomyelitis later result in a so-called bone cyst. The remainder retain their primary pathologic picture of hemorrhagic osteomyelitis, which is frequently termed medullary giant-cell sarcoma. I think they are not sarcomas, because we know that the giant cells found in the mass are not tumor cells. Further, I have been able experimentally to produce the lesion simulating so-called medullary giant-cell sarcoma.

THE TREATMENT OF SCOLIOSIS *

FRANK E. PECKHAM, M.D.
PROVIDENCE, R. I.

From the earliest times, scoliosis has been written about and described in such a way as to make it the most complex subject in orthopedics. It would seem that if the explanations and descriptions could be reduced to simpler terms, the principles of treatment would be fewer and simpler, even though the ultimate results were still difficult of attainment. Rational treatment of any disease or abnormal condition is founded directly on etiology and pathology. In these later days, physiology is a little better known and is becoming of tremendous importance in giving a clearer understanding of many conditions.

In the first place, there must be a decision as to whether scoliosis is a deformity unaccompanied by disease of the structures involved, or whether there is a diseased condition of the bones and ligaments. My studies have convinced me that the bones and ligaments in these cases are in a softened condition, otherwise deformity of this type could not have developed. Also, it would seem to me that the term "scoliosis" should be used only to indicate a syndrome of a deformity dependent on such softened and yielding structures. I cannot agree with the idea that scoliosis is deformity without disease. There are thousands of children habitually assuming faulty positions every day, but only in the few does scoliosis develop, and in those few, the bones and ligaments are too soft to support the superincumbent body weight.

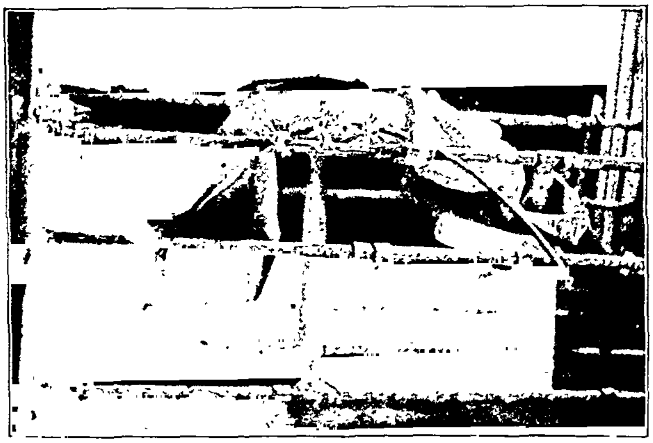

Fig. 1.—Patient in position on frame.

There are deformities simulating scoliosis. A child may have a short leg, thereby producing a tilting of the pelvis, in consequence of which curves appear in the spinal column and one shoulder is carried lower than its mate. Raising the shoe on the short leg immediately corrects the deformity, thus demonstrating the absence of the syndrome of a "deformity dependent upon softened and yielding structures."

Case 1.—A mill girl consulted me complaining of a low shoulder and a curved spine. She had been carrying a heavy basket every day in her work and always on the same shoulder. A change of occupation was followed by a restoration to correct form. Here also there was entire absence of the syndrome. These cases, therefore, are not real scolioses, and some other nomenclature should be applied, possibly "pseudoscolioses."

---

* Read before the Section on Orthopedic Surgery at the Sixty-Eighth Annual Session of the American Medical Association, New York, June, 1917.

Case 2.—A young married woman with a moderate deformity of the spine presented herself with the following conditions: Her first child was 4 months old and very greedy. In this way, the strength of the mother had been much diminished. One shoulder was low, the spine was becoming curved, and there was an increasing amount of pain in the back. In other words, calcium metabolism had been interfered with. As I did not wish to apply a plaster jacket while the breasts contained milk, the advice was given to wean the baby and report for a jacket when the milk had completely disappeared. Here was a developing deformity dependent on softened and yielding structures; in other words, a scoliosis. This patient waited about three months before returning, at which time the back had completely straightened, the pain had disappeared, and the young woman presented every appearance of perfect health.

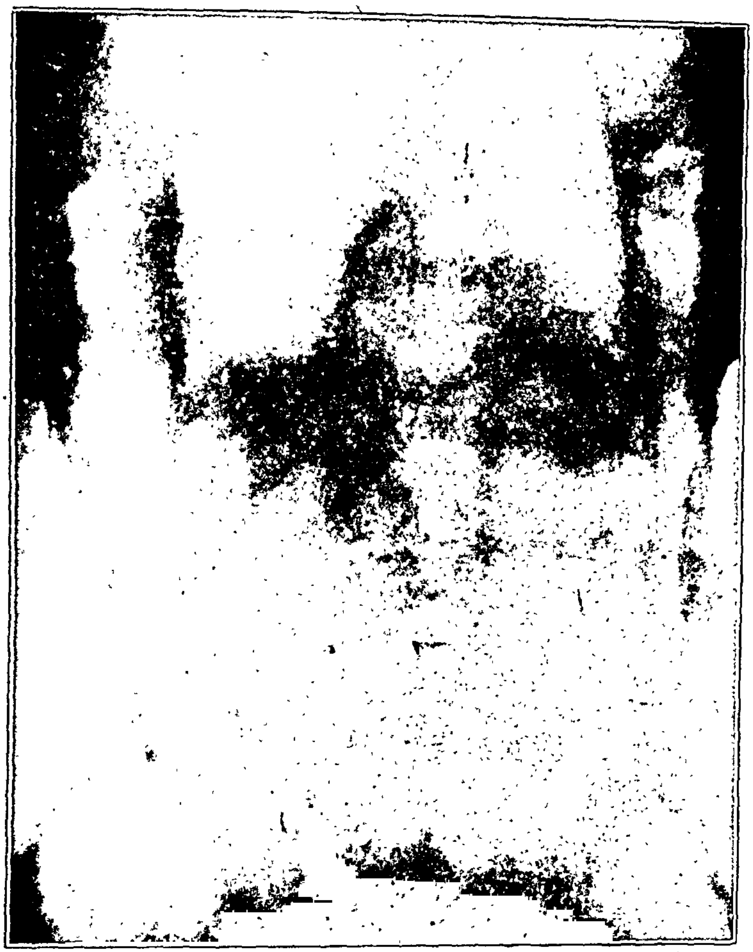

Fig. 2 (Case 3).—Condition, March 24, 1917.

I have previously reported the case of a girl, aged 7, with a severe grade of scoliosis due to much softened bony and ligamentous structures following an attack of influenza, and another presenting the condition of hypothyroidism. Here the deformity disappeared, under the administration of thyroid extract.[1]

The foregoing cases appeal to me as representing the difference between a real scoliosis and what perhaps might be considered a pseudoscoliosis, the one without disease of the involved structures, the other with. Deformity of the spine following an infantile paralysis might be termed a paralytic scoliosis, just as, similarly, we speak of a paralytic clubfoot.

If the hypothesis be accepted that scoliosis is dependent on a softened condition of the bones and ligaments, due presumably to some interference with calcium metabolism, then it seems fair to consider that it is the downward pressure of the head and body weight on this disease-weakened structure which produces the deformity. The comparison should not be with a clubfoot, but with a bow-leg or knock-knee; in other words, softened bony structures yielding to superincumbent body weight.

The etiologic factor then becomes the process which interferes with calcium metabolism. This may be rachitis, infections (including autointoxications), or the rapid growth which sometimes takes place in adolescence. The physiology of the endocrine organs is of great importance, and the thyroid gland, in particular, is supposed to preside over calcium fixation. When these physiologic processes go wrong, trouble arises.

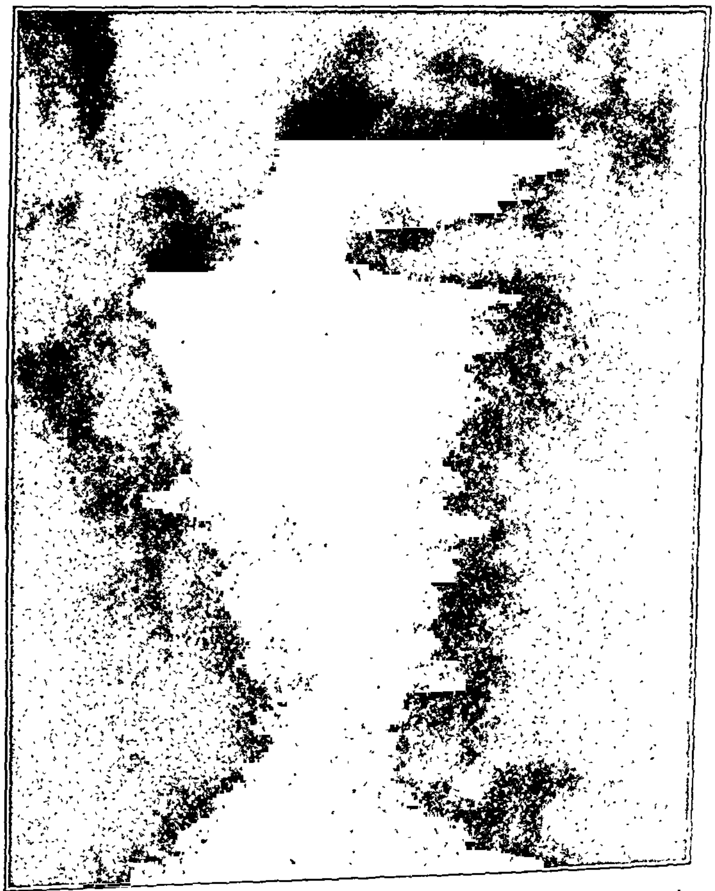

Fig. 3 (Case 4).—Spine of a girl, aged 18, before beginning the present form of jackets, Jan. 6, 1916.

These are some of the factors which produce a softening of the vertebrae and ligaments. These vertebrae and ligaments, yielding to the superincumbent body weight, become pushed downward and thus the deformity of scoliosis is produced. It is a scoliosis from the earliest stages. There may be different degrees of severity, both of symptoms and of deformity, but it is scoliosis all the way through. The duration of this softened condition usually extends through quite a period of time, and it is the treatment of this condition to which sufficient attention has not been given. This is pure physiology. In cases of hypothyroidism, the thyroid gland may be indicated. In the rapid growth of adolescence when there has been no scoliosis, but the symptoms have been backache and headache, swollen eyelids, the entire lack of strength and often the appearance of stupidity, the administration of thyroid extract will usually produce the desired result. One case referred to above, in which scoliosis was present in addition to all of these symptoms, the deformity disappeared, as illustrated in the original article. In other cases when it was uncertain what process was going on, I have used the mixed gland tablets. With more definite knowledge along these lines, much better physiologic results must be obtained.

[1] Peckham, F. E.: Am. Jour. Orthop. Surg., December, 1916; Rhode Island Med. Jour., January, 1917.

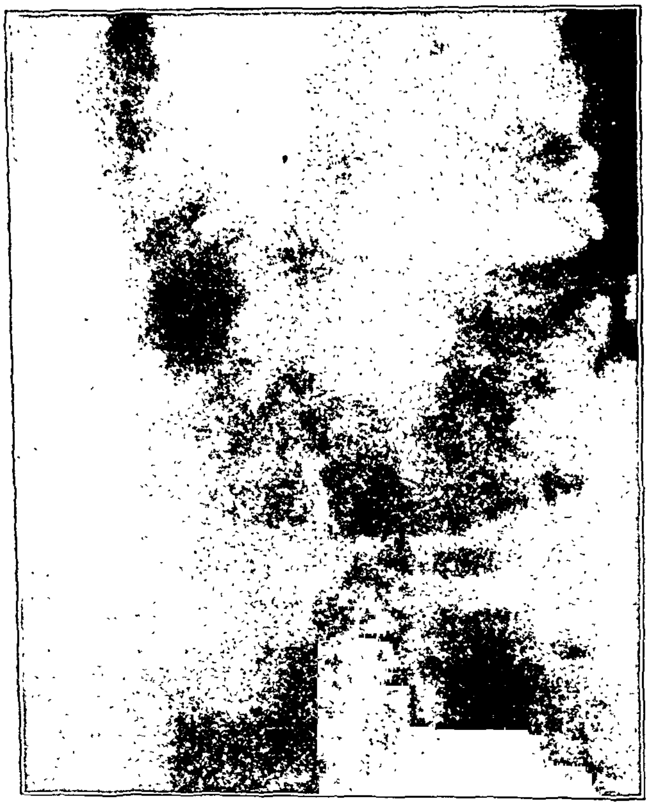

Fig. 4 (Case 4).—March, 1916; second jacket.

Regarding the mechanical treatment, I have tried to make it such that these patients could continue their customary duties without interruption. Consequently some of them are attending school daily, others are working in the shops, and one stenographer is continuing her work without any difficulty. The patient is still placed face down over a curved frame (Fig. 1), so that the spine becomes lengthened and some of the curves are improved by the position alone. With the body in different degrees of flexion, rotary pulls are made, thus correcting as much as may be possible, and the patient still remain comfortable. Traction on head and feet, which was used in earlier attempts, has been omitted. It caused so much pressure on the stomach that nausea and vomiting resulted. In my work thus far, a new jacket has been applied once a month, in order to start all over again at frequent intervals, with the body in as good a position as the patient will tolerate.

Case 3.—J. S., first reported in May, 1916, is retained in plaster, as shown in Figure 2.

Case 4.—E. M., a girl, had practically attained her growth when the present method of treatment was begun. For the preceding year, other forms of jackets and braces had been tried, but the deformity was increasing, until in January, 1916, the condition was as is shown in Figure 3. Jackets have been reapplied monthly, and Figure 4 shows the condition in March, 1916. Figures 5 and 6 show the condition as late as April, 1917. She is now 19 years of age, and still improving. The last picture shows still further improvement, but came in too late for publication.

266 Benefit Street.

ABSTRACT OF DISCUSSION

Dr. Albert H. Freiberg, Cincinnati: Many years ago I was associated as assistant with the late Dr. J. Wolff in Berlin, at the time when discussion of the law of the transformation of bones was going on. It had been the theory of many before this time, twenty-five years ago, that cases of adolescent scoliosis, particularly, were produced by some softening disease of bone, which they used also to explain other deformities such as flatfoot and coxa vara, which they considered akin to rickets. So they spoke of adolescent rickets. Wolff came back at them with the argument that they were unable to produce any tangible evidence of its existence, and they were not able to do so. It is not fair to assume that there is no such distinction as that between attitudinal or postural and structural scoliosis. To any one who has examined persons in the third or fourth decade of life who have had a short leg uncorrected, with a curve of the spine, disappearing entirely when in the recumbent position, showing the absence of any structural change, and especially to any one who has made roentgenograms of such patients, as I have done, and demonstrated that no structural changes had occurred, it seems to be impossible that we should hold longer the belief that no such distinction should be made. That the one condition may pass into the other must, I think, be assumed for the present, but that they are distinct conditions must also, I believe, be assumed. Of course the old views regarding adolescent rickets were expressed when we knew nothing of endocrine physiology. We know little enough about it now to be willing to say that it is possible to tell in any case whether it is the thyroid, the suprarenal or the thymus, or simply a disturbance of the endocrine balance, which is responsible for such changes in the bones, which we assume, after a study of physiologic experiments, to result sometimes, at least, from a disturbance of the endocrine balance. I have had the experience, as many others have, of being surprised at a very marked difference in the response to treatment in physically similar cases of structural scoliosis. I have been unable to tell by the severity of the physical changes the degree in which the patient would respond to corrective attempts on my part. I have found

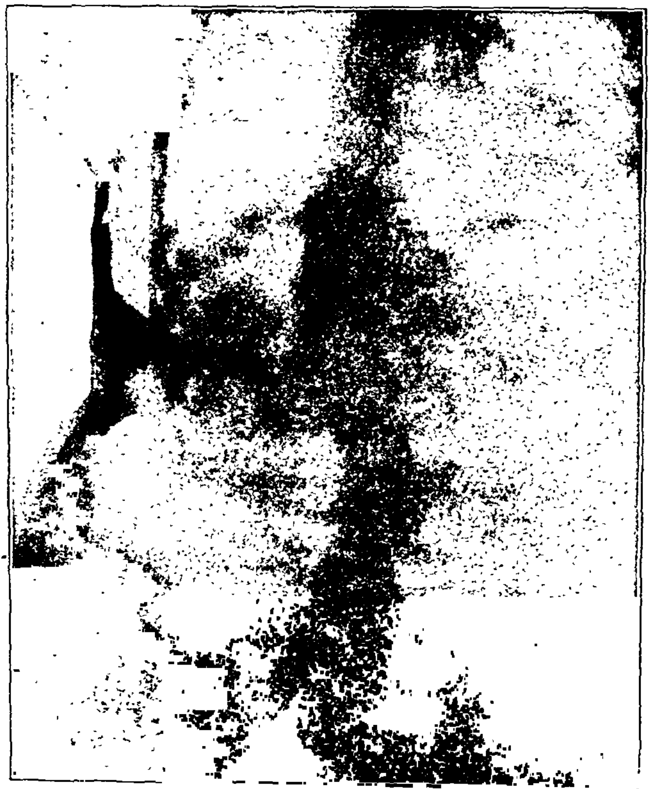

Fig. 5 (Case 4).—June 24, 1916; sixth jacket.

sometimes that comparatively slight deformities yield practically not at all, while at other times, rather severe deformity yields easily. It has been my assumption for some time, with a more or less theoretical basis, I will acknowledge, that the differences in these cases were to be explained by differences in that individual, as compared with others of similarly severe deformity, in the resistance of the tissues—perhaps not in the bone alone. I have for some time felt that in certain individuals there is probably a great disturbance of the whole endocrine balance that is to be considered in connection with the disturbance occurring at the time of puberty, and that these things may occur under similar circumstances at later periods in life. I should like to ask whether Dr. Peckham has reason to believe that there is any mechanical advantage in applying jackets with the patient face downward rather than face upward in a flexed position.

Dr. E. H. Arnold, New Haven, Conn.: I can do no better than to draw attention to the classification of deformities in Hoffa's book on orthopedics, which I think is serviceable at present. If he defines deformity as a change of shape in a bone or a joint, I think any or all of these symptom complexes must be scoliosis, if they are changes in direction of two bones. Therefore, there is no such thing as pseudoscoliosis, even in cases that show no change in bone structure. Hoffa classified the deformities into congenital and acquired, and divided both into contractures and weight deformities. Then you simply need to go down his list of contractures, section by section—skin, muscle tissue, nerve tissue, etc.—to find the particular kind. This classification covers a great many cases. I think it will throw light on a statement by Dr. Allen in regard to the possible use of scar tissue in holding a spine of the paralytic type; and it will help Dr. Hibbs and others in establishing the correctability of these cases by fusion, and also assist in the correction of weight deformities. These etiologic factors have always been, to me, the determining factors. If one has the symptom complex one must find the etiologic factor; and that has a great range in variety. We cannot always find out why bone softens. It sometimes softens from defects in the several internal secretions, and the deformities may be immense. Hoffa's table has always helped me to make the etiologic diagnosis. That, once established, leads to more intelligent treatment.

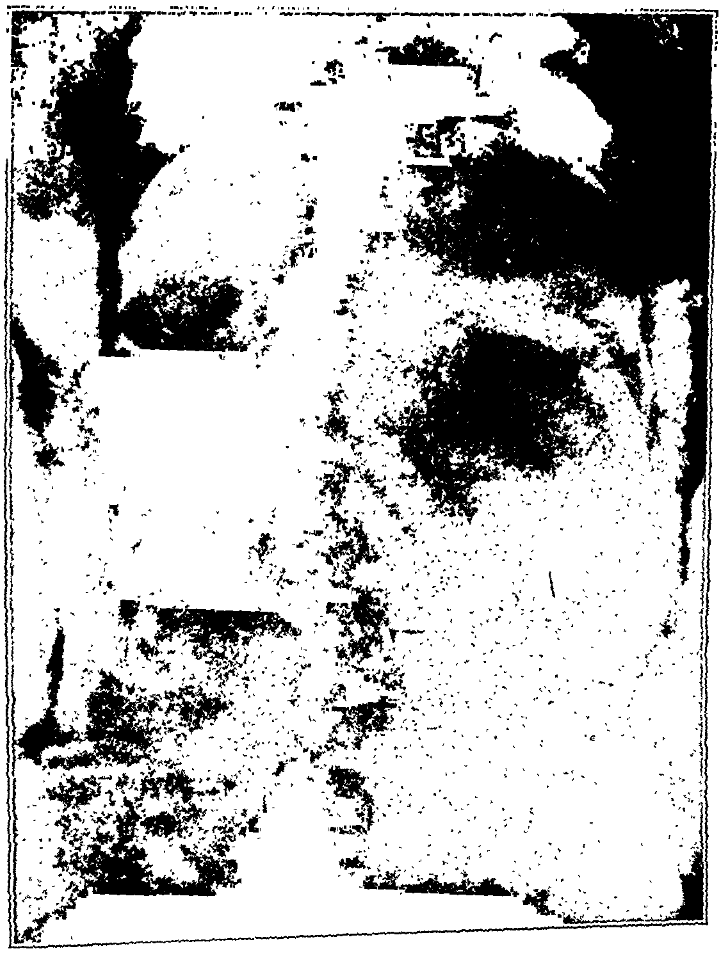

Fig. 6 (Case 4).—Condition of spine, April 16, 1917.

I also wish that Dr. Peckham would tell us how to apply these jackets. Dr. Abbott, some years ago, owing to some rather painful experience, changed his mind about the use of the heroic method of treatment. He told me that within one year he had changed from a corset that overcorrected markedly and was kept on for a long time, to one less heroic and more frequently applied, believing that the latter would give better results. I think that Dr. Peckham's is an attempt in that direction.

Dr. Royal Whitman, New York: I think scoliosis should be divided etiologically into many different classes. We all recognize the fact that certain weak individuals are predisposed to scoliosis and other postural deformities, but preliminary softening of the bone can hardly be a general cause. In order to support such a contention one must explain why five or six girls are affected to one boy. Also, why the deformity of scoliosis often increases in later years, long after any original softening of the bone has disappeared. Furthermore, all the postural deformities must be included. I am much interested in the paper quite apart from the question of etiology and should like to hear more of the details of the application of the jacket.

Dr. Virgil P. Gibney, New York: I should like to have Dr. Peckham say in closing what real evidence he has that the bones are softened.

Dr. Samuel Kleinberg, New York: The severity of the deformity affords no basis of judgment as to the outcome of treatment. We often see cases of mild rotation deformities that resist treatment for a long time and more stubbornly than the severe types. It seems to me that the long total curves are more amenable to treatment than the double curves, particularly the S-shaped curve to which I called attention some time ago. A curve with the dorsal deformity equal to the lumbar is difficult to correct by any known method. The types that have resisted all manner of treatment are the razorback deformity and those with congenital lesions. I have had twenty or twenty-five with congenital malformations of one or more vertebrae, and it is difficult to make any impression on them, even when the curve is very mild. When one has a malformation of the lumbar, or possibly the dorsal, vertebrae, it is impossible to make a serious impression on it. With the milder forms that have not existed a long time we not only can make an impression on the deformity, but correct it in great part by more than one method; not only by the Abbott method, but also by others; for instance, treatment in the erect posture. I have had some patients whom I have treated with jackets in the erect posture, in whom the deformity has become reduced and the patient improved as much as by the more severe method suggested by Dr. Abbott.

I should like to call attention to one type that has interested me, namely, the paralytic back. Paralytic scoliosis is often of a severe type. Can we gain a great deal by placing these patients on their back for a long time? I have recently had two patients who have improved a great deal. Both have been on their backs for six months, using corrective jackets, with a great deal of attention to the proper application of pressure over the deformity and allowing for expansion of the other side. I think it is a mistake to allow these patients to walk about.

Dr. James W. Sever, Boston: As a matter of fact, in the normal mechanics of the spine, as shown by the experiments carried out by Dr. Lovett, the dorsal spine in the flexed position increases very little in total length; but he has also shown that rotation is freest in the dorsal region when in the erect position and less in the flexed. The more the person is flexed forward, the more the spine is locked against rotation; and what is gained in the total length of the spine is very little. So I imagine that mechanically this position is largely an empirical one.

Dr. Frank E. Peckham, Providence, R. I.: The frame that I employ is the gas pipe frame, with cross strips of canvas placed between the sides and canvas going from one end of the frame to the other, so that the curve is kept tight. When the rotary pulls come it is easy to encircle the patient with plaster.

It appears to me as I perform my experiments that when the patient is laid down on a curved surface with the spine upward there is some lengthening and untwisting, simply from position; and if to that is added a rotary pull, more is accomplished. I hope this answers the question about the way of putting on the jacket.

It is rarely that bone softening is not found. We cannot, of course, cut these patients up in order to see how soft the bones are. I was interested to see a patient whose case I have reported straighten up on the administration of thyroid extract. There must have been something to cause restoration of form. Nature tries to grow a thing straight when it has a chance, and with restoration of normal physiology that was what took place. I had an interesting case in a little girl with a slight curve that absolutely resisted treatment. I could push it straight, but it would not stay. I gave her thyroid and she braced up immensely. Then she suddenly went to pieces physically and it was discovered that she had old roots in her gums. They were removed and she has braced up and done well since. Her spine is about straight, and is, I believe, on the road to permanent recovery. That was a mild case, but it was extremely resistant.

PAIN IN THE ARM: SUBDELTOID (SUBACROMIAL) BURSITIS

A FURTHER STUDY OF ITS CLINICAL TYPES, PATHOLOGY AND TREATMENT *

WALTER M. BRICKNER, M.D.
Fellow of the American College of Surgeons; Associate Surgeon, Mount Sinai Hospital; Captain, Medical Reserve Corps, U. S. Army
NEW YORK

The statement may appear bold, even to a gathering of orthopedists, that most of the cases of persistent pain in the upper arm, so often treated for "rheumatism" and "neuritis," are surgical affections, at least in that they require mechanical treatment.

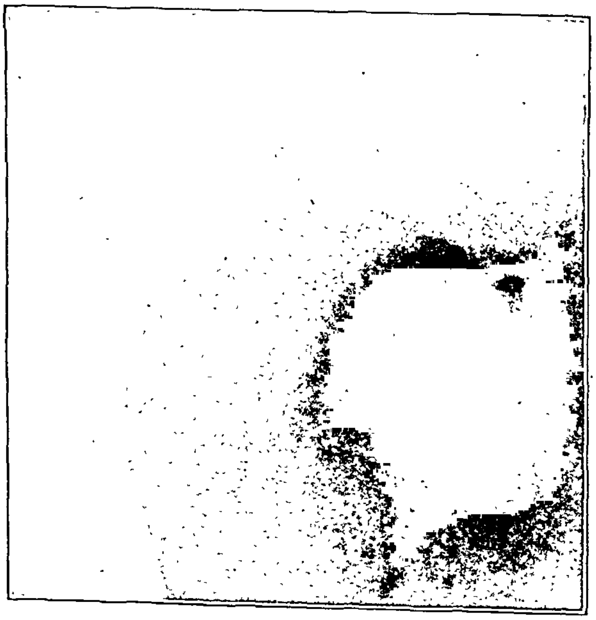

Fig. 1.—Large semifluid lime deposit beneath the bursa.

In the absence of arthritis or of symptoms in other parts of the body, the diagnosis of rheumatism, as an explanation of pain in the arm, is quite untenable, and need not detain us.

Brachial neuritis is a real condition but a comparatively uncommon one. When well established, it should be marked by motor, trophic or sensory signs, as well as by nerve tenderness. In all cases it is important to determine, by careful examination, including roentgenography, whether the neuritis is not simulated or produced by some other lesion. Pain in the left arm, usually referred especially to the flexor aspects of the elbow and wrist, may be associated with an anginal condition and, as such, may be symptomatic, among other things, of tobacco poisoning.

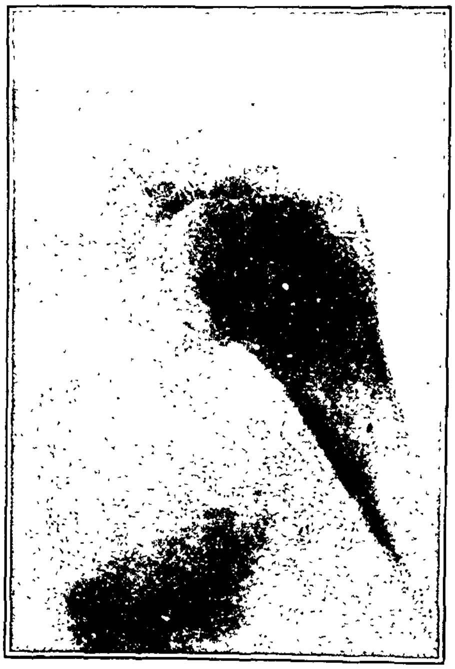

Fig. 2.—Very small deposit near the supraspinatus insertion.

Of the surgical conditions, aside from grosser and more evident lesions, that cause pain in the arm, we must bear in mind cervical rib, fracture of the greater tuberosity of the humerus (which may occur from comparatively mild internal as well as external violence), spontaneously reduced luxation of the shoulder, subluxation[1] of the shoulder (either of which may be produced, in some persons, by slight violence), mild sprain of the shoulder, periostitis of various origin, and neoplastic and inflammatory diseases of the bones, especially the humerus (among which chronic bone abscess, cortical or medullary,[2] should be mentioned as an occasional cause of severe, persistent pain).

Far more common than any or all of these causes of pain in the arm and sometimes, but by no means always, also in the shoulder, is subdeltoid (subacromial) bursitis. It is, indeed, so often the cause of the complaint, that it should be thought of first.

In earlier communications[3] concerning the pathology, pathogenesis and operative treatment of subdel-

Sc., 1915, **149**, 351; Shoulder Disability: A Further Study of Its Varieties and their Treatment, Interstate Med. Jour., April, 1915; The Location and Cause of Lime Deposits Associated with Subacromial Bursitis: "Excision of the Bursa," Am. Jour. Surg., April, 1916.

SYMPTOMS

The symptoms of subdeltoid bursitis are two: pain, and disability in shoulder movements.

Pain is present in almost all cases. It is usually referred to the upper arm, anteriorly or externally, from the level of the deltoid insertion toward or to the elbow. Very often, but by no means always, it is referred also to the shoulder, usually its outer aspect. Sometimes it radiates into the forearm, the hand, the fingers or the neck. The pain may be fairly constant, or intermittent, or only on motion. Often it is worse at night.

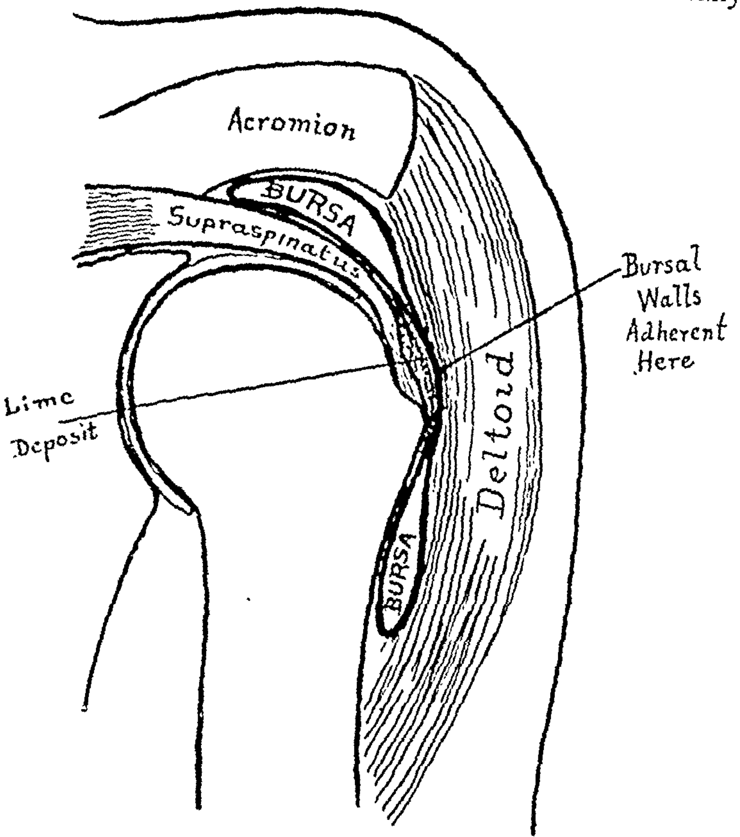

Fig. 7.—Diagram showing why many surgeons think they find the deposit in the bursa. Over the mass the two bursal walls are adherent and, unless separated by the operator, they are incised as one.

Disability of movement may be entirely absent, especially in chronic cases. In the early stage, however, abduction, at least, is inhibited or painful. This movement and internal rotation are chiefly affected, but in varying degrees. The patient may be able to raise his arm only a little, or he may be able to abduct insufficiently to brush his hair. The interference with internal rotation may be very great or moderate; the patient may be unable to put his hand in his trousers pocket, or unable to reach behind his back, or unable to raise his hand on his back to the opposite scapula. External rotation is usually little affected; but sometimes is much inhibited. The arm can be swung backward and forward. There is no ankylosis.

PHYSICAL SIGNS

In the early stage there may be slight swelling due to serous effusion. In most cases, when the patient presents himself there is no swelling. On the contrary, there is often to be noted a flattening, due to atrophy of the deltoid. The supraspinatus and infraspinatus muscles may also be atrophied. Pressure on the bursa below the tip of the acromion process is sometimes painful, but it is usually painless. The only tender point that I find quite constantly is anteriorly, over the lesser tuberosity. When this point is very tender (comparison should be made with the opposite shoulder) it is fairly diagnostic in association with the symptoms described.

Roentgenography is important. If nothing is shown, it does not deny, rather it supports, the diagnosis of bursitis. If the shadow of a lime deposit is seen, however small it may be, the diagnosis is established beyond doubt.[8] Finally, the roentgenogram may show some unsuspected lesion, namely, syphilis or tuberculosis of the head of the humerus, or a small fracture of its tuberosity (the latter, as I have said, clinically the same lesion as supraspinatus injury and, like it, probably also having a bursitis associated with it).

CLINICAL FORMS

Codman's[6] classification into three types, "acute or spasmodic, subacute or adherent and chronic or nonadherent," is unsatisfactory from the anatomic side, for in all cases, acute or chronic, the pathology is, I believe, the same — an adhesive bursitis. We cannot recognize, therefore, a nonadherent and an adherent type, nor it seems to me, can we make a satisfactory distinction under the titles "subacute" and "chronic."

In my experience the cases present themselves in the following forms which, however, are not to be sharply separated: acute, "hyperacute," chronic, chronic with exacerbations.

In acute cases, pain and stiffness develop rapidly and reach a maximum in about three days. The pain is quite severe and constant, and subsides little or not at all at night. The arm can be only slightly abducted without great pain. There is spasm of the shoulder muscles, increased by attempted abduction or internal rotation, active or passive.

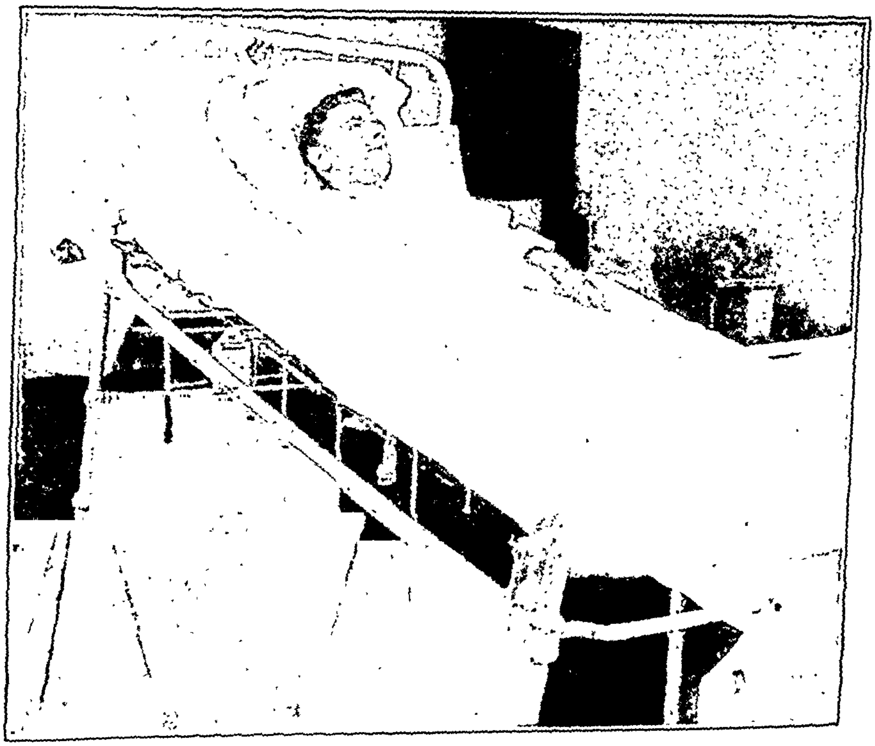

Fig. 8.—My easily regulable method of automatically restoring abduction in the treatment of shoulder disability.

The term "hyperacute" I use to indicate not so much the rapid development of the symptoms as their severity. The pain is very great. The patient hugs his arm to his chest, and the slightest attempt to raise it causes severe spasm. There is a rapid development of atrophy of the deltoideus and the spinati. Radiation of the pain into the fingers, with this atrophy, may deceive even a neurologist into the diagnosis of brachial neuritis. Indeed, the early appearance of atrophy of these three muscles suggests that there may be some associated localized neuritis; disuse for a short period seems not quite sufficient to explain it.

---

[8] Occasionally the tendon lesion exists without an overlying bursitis, but the symptomatology and treatment are the same.

In both the acute and the "hyperacute" forms, tenderness at the point I have described is exquisite.

Acute subdeltoid bursitis may gradually subside completely. More often it passes into the chronic form.

Chronic subdeltoid bursitis begins in the acute form, or is of the same severity throughout. The pain is often annoying rather than unendurable. It may be quite intermittent, varying in severity. Often it is present only on certain motions (as in pulling on an overcoat sleeve, or attempting to comb the hair). Abduction may be limited to 45, 90 or 130 degrees; internal rotation may be much or little retarded. Passive movements are usually a little freer than active. External rotation is sometimes limited. In many cases the movements are perfect, but usually they are then more or less painful. Tenderness on pressure over the lesser tuberosity is usually present and often great. There may or may not be atrophy of the deltoideus and spinati.

This chronic form persists for months or years. Usually it subsides, with or without treatment, sometimes in spite of certain treatments. The lime deposit, if there is one, may gradually disappear completely.

The "chronic form with exacerbations" is of those cases, lasting for years, in which there is often a recession of symptoms, more or less complete, for long periods, but in which every few weeks or few months there is a severe exacerbation in which the symptoms approach those of the acute or even the "hyperacute" form.

TREATMENT

I am not inclined to place much confidence in electricity, baking, violet ray, internal medication or even massage. It is true, no doubt, that patients have recovered, by reason of such measures, or in spite of them. On the other hand, most of the patients referred to me have abandoned these treatments because their symptoms were unrelieved or even aggravated by them.

My first object, in the management of subdeltoid bursitis, is to overcome the abduction disability, the spasm (if there is any) and thereby, to a large extent, the pain. This I do by a simple automatic abduction method elsewhere described.[9] I put the patient to bed supported on several pillows and with his arm raised as far as he comfortably can abduct it. A towel or bandage sling is passed from the wrist or elbow to the head of the bed, and this end of the bed is raised on blocks or chairs (Fig. 8). It will often be noted that as soon as the patient is comfortably recumbent he can abduct his arm more than when standing. As he gradually slides down in bed his arm correspondingly goes up; and it is no rare experience in a patient who has not abducted his arm more than 45 degrees in many months to find it thus fully and painlessly abducted in twenty-four hours. Usually it takes a few days longer. If the patient cannot sleep with his arm in this sling, or cannot maintain that position continuously, he may intermit this gradual traction. Codein and acetyl-salicylic acid are helpful aids in overcoming the pain the first day or two. When passive abduction is thus fairly secured, active abduction is restored with it, and the pain soon disappears also in most cases. The abduction is maintained, and internal rotation is secured by after-treatment with Indian club exercises.

This plan of treatment is equally applicable to acute, "hyperacute," and chronic cases. It is of little or no value in chronic cases with no loss of motion. These cases, in which pain is the only symptom, are, in my experience, the most difficult to cure. Fortunately, the patients usually recover spontaneously.

I have come to the belief that most patients who have subdeltoid bursitis recover under this plan of treatment in bed with automatic abduction, or the trouble subsides spontaneously, though slowly. There are some, however, that do not thus recover and some that, though they may eventually do so, meanwhile suffer so much pain, loss of function and interference with occupation that operation is to be recommended as a means of prompt cure. I would therefore advise operation in the following cases: 1. In the chronic form with exacerbations. These patients have been through all sorts of treatment for years; their sufferings during the periods of exacerbation are severe; they show no tendency to spontaneous recovery. 2. In acute, "hyperacute" and chronic cases in which the automatic abduction in bed fails to restore function and to relieve pain and spasm.

The operation I employ I have previously described.[10] In consists in: splitting the deltoid; raising the outer wall of the bursa from the inner and incising it; dividing all adhesions in the bursa; incising and retracting the floor of the bursa; removing the deposit, if extratendinous, and suturing any tear in the supraspinatus tendon; or incising the tendon wherever indicated by the roentgenogram and excising the deposits with surrounding tendon fibers, and reuniting the tendon with chromicized catgut (if the defect is not too large); suturing the floor of the bursa with a fine running catgut stitch; anointing the interior of the bursa with a thin layer of petrolatum; suturing the outer wall of the bursa; suturing in layers, without drainage, the deltoid muscle, the deltoid fascia and the skin; abducting the arm in plaster of Paris for about a week.

The petrolatum may not be important. The reconstruction of the bursal walls is not essential, but it aims at an anatomic operation. The abducted position is also not essential, but I believe that it shortens the after-treatment, which consists in Indian club exercises and other devices to restore internal rotation and full abduction.

All the patients thus operated on have been promptly relieved of pain and early restored to full activity. In only one patient, a physician, was there any complication — a brachial phlebitis which retarded his recovery a few weeks.

In one case of chronic bursitis without any lime deposit, in which the pain and disability continued, with exacerbations, for years, division of the adhesions and abduction for one week were followed by permanent cure. This is the only case without lime deposit in which I have operated. It illustrates, first, that the roentgenogram of a deposit is not essential to a diagnosis of subdeltoid bursitis and, *second*, that division of the adhesions (and placing petrolatum in the bursa) will effect a cure when conservative measures fail, even in the absence of the lime mass.

ABSTRACT OF DISCUSSION

Dr. Eli Moschcowitz, New York: [Dr. Moschowitz demonstrated lantern slides made from specimens of portions of supraspinatus tendons submitted by Dr. Brickner for pathologic examination.] The lesion is a tendonitis, characterized by necrosis or hyaline degeneration of the tendon with secondary calcification, and a reactive granulation tissue around these areas of necrosis or calcification. The morphologic changes parallel the duration of the disease; thus, in long standing cases abundant scar tissue is present, while in early cases the granulation tissue is richly cellular. I believe that the necrosis was due to actual death of tendon tissue and was not of hemorrhagic origin because blood pigment was entirely absent. The necrosis is, in all probability, due to cutting off of the meager blood supply of the tendon consequent on the trauma. Calcification inevitably follows in those portions of the tendon that have undergone necrosis or hyaline degeneration. This is the usual consequence in other tissues of the human frame. The remarkable feature is the early incidence of the calcification. We are accustomed to think of calcification as occurring only after the tissue has been dead for some time, but in the cases that Dr. Brickner reports calcification occurs as early as forty-eight hours after the onset of symptoms. The only possible explanation of this early calcification is found in the results of the experiments of Litten and Schujeninoff, who found lime twenty-four hours after traumatic necrosis of the kidney and muscle, respectively. Perhaps the peculiar predilection to early calcification may be due to certain biochemical products in the tendon itself (collagen?).

Dr. J. Bion Bogart, Brooklyn: I want to say a word from the standpoint of one who suffered for four and a half years and has not been cured. Four and a half years ago I had a surgical infection through the index finger which resulted in metastatic infection of the shoulder joint and which was opened and drained and afterward had extension for four weeks. I was able to work after that, though I still have limitation of motion in the joint, but not ankylosis. My chief symptom, in addition to limitation of motion, is pain, which is not present except on motion or pressure. One of the most serious difficulties that I labor under is inability to turn on my left side to sleep at night. I cannot lie on that shoulder because the pressure causes too much pain. When I raise my arm it causes pain, which runs down the arm.

In my own case, so far as I know, there was no injury. I think that the same infection that caused the metastasis to the shoulder joint produced the bursitis, which was not, however, recognized at the time. Following recovery from the early symptoms, I had treatment with baking and massage for two months, after which I gave it up, because I did not gain anything in motion and the treatments were followed by pain. This kind of treatment did not seem to do me any good, but harm, if anything. I have done nothing since for the last four years. I was roentgen rayed at the time of my infection, and since then, a year and a half ago. The gentleman who did it later, Dr. Wasch, is here. There was no calcareous deposit then, and, so far as I know, there is none now.

Now what is it that causes my pain? I have none when the arm is at rest, but only on pressure or motion. If adhesions cause it in the cases in which there are no deposits, I think they are sure to be reformed after operation; and I do not see how relief can come from the operation in such cases as mine. I do not see, either, how relief could come from forcible stretching of the arm upward. It cannot be done immediately, but only gradually; but, as the scapula moves with the arm, I do not see how benefit could come in that way.

Dr. Fred J. Fassett, Seattle: Have any of those present seen the very rapid disappearance of these lime deposits? I have seen one case, reported by Dr. Risley of Boston, and also one of my own, in which the disappearance of the calcification was so rapid as to cause a question as to the authenticity of the plates.

Dr. Milton G. Wasch, Brooklyn: I have been fortunate enough to have made roentgenograms in a great many of these cases. Within the last six months I have seen twenty-five. It has always been my custom to make roentgenograms of the opposite shoulder for comparative study, and I have been surprised, in a good many cases, to find lime salts in the opposite shoulder, in which the patient had not complained of any symptoms either at that time or previously. I, therefore, feel that the statement that deposits of lime salts form in one or two days is doubtful. I think when the patient complains of symptoms due to subacromial bursitis the probability is in most cases that the calcium has already been deposited and that the condition and suffering are from an acute exacerbation of a chronic calcifying bursitis.

Dr. Willis C. Campbell, Memphis, Tenn.: I should like to emphasize a point that Dr. Brickner made in his paper, that mild trauma is the frequent cause of this condition; and also that this injury may be overshadowed when other parts are seriously damaged. I had such a case in a young man. The injury was received in an automobile accident and he did not recognize the trouble in his shoulder for six weeks. By that time there was beginning atrophy. I did not see him for six months after the accident; then there was extreme atrophy and considerable trophic disturbance in the arm with abduction totally limited. Relief was soon given by simple abduction in a plaster cast, followed by massage, etc.

Dr. Heinrich Wolf, New York: I have had occasion to treat a few hundred cases of subacromial bursitis and should like to know what stand Dr. Brickner takes now regarding the infectious origin of some of these cases. We know that a great many are traumatic.

With particular reference to the remarks of the last speaker, I would say that I have noticed a great many cases following Colles' fracture of the wrist. If a patient falls on his hand and gets a fracture of his wrist, the pain in his wrist is so severe that he neglects a probable slight injury in the shoulder joint. I have seen about twenty cases of this in the dispensary of the Mount Sinai Hospital, in which subacromial bursitis developed five or six weeks after the injury to the wrist.

Then I have seen patients get a similar condition after infectious conditions in the hands. I cannot explain in what way an infection in the hand can be followed by subacromial bursitis, but I have seen it too often to consider it an accident. I hope that Dr. Brickner will be able to answer this question, particularly about the infectious condition. I have seen lately quite a number of cases of acute bursitis in which I was positively able to trace it to infection in the teeth. I know that Dr. Brickner does not believe that this is possible; but I mean, of course, only a certain number of cases. I want to say that I have seen other etiologic factors, but that in these particular cases removal of the teeth relieved the pain.

Dr. John Dunlop, Washington, D. C.: In some cases with a lime deposit in which operation was performed I found absolutely no adhesion. I should like to ask Dr. Brickner whether he considers that all cases of lime deposit have subacromial bursitis. I think in most cases they are quite separate conditions.

I believe there is nothing in Dr. Brickner's exposition, other than what Dr. Codman brought out in his paper in 1908. I have seen four cases of such deposits, in one of which operation was performed. In the first three cases that I saw operation was refused. I put the arm up in the abducted position and the patients got as well as any other cases of subacromial bursitis that I have seen. The fourth case was in a man who had so much pain that half a grain of morphin every four hours would not quiet him. I tried to put his arm up in the abducted position under nitrous oxid anesthesia. This increased the pain so markedly, however, that I operated. Dr. Brickner showed that he found adhesions. I found no adhesions in this case. I cut down to the bursa and demonstrated it to be as large, as Dr. Codman explained, as the palm of the hand. I saw the white mass shining through the base of the bursa and cut down on this and was able to scoop it out with a spoon. It was of the consistence of a soft toothpaste and quite white. I sent it to the laboratory of the Army Medical School and hoped to get a report on it from there; but it was lost. I did, however, get a negative bacteriologic report. I passed a probe well up within the sheath of the supraspinatus muscle and was sure that I was within it. The lower and upper surfaces of the bursa were closed and the man got a perfect functional result.

The day after I heard Dr. Brickner read his paper I had a case in an officer in the Marine Corps who refused operation. I put his arm up in abduction and he got well. Later, he had symptoms in the other shoulder, of which I had not made roentgenograms when I operated on the first shoulder. I treated that, and he got so well that he now plays tennis and golf every day. He still has the deposit in the shoulder, eighteen months after the diagnosis was made.

I do not agree with Dr. Brickner that these deposits occur within a few hours. We have no evidence that they do, for we do not take roentgenograms of our patients before. I think the symptoms come on from some trauma due to the deposit which may have been there for weeks, months or years before. It seems to me, from my four cases, in three of which there was no operation, that these patients will get well without operation.

Dr. Walter M. Brickner, New York: Dr. Dunlop reports that he found a lime deposit in the tendon in a case in which there were no adhesions in the bursa. That does occur. I referred to it in an earlier paper as "calcareous tendinitis without bursitis." I do not wish to claim anything that belongs to Codman, who was the first to suggest, in three cases, that the deposit is under the bursa. He speaks of it, however, as wenlike and cystlike, which it is not; and the conception of it as being often wholly within the tendon was not brought forth by Codman.

Concerning the rapid formation of the deposit, you are right in questioning my statement. The deposit may have been there before the symptoms called for a roentgenogram, but I have, not only once, but several times, found patients who, two days after a fall on the shoulder, or a lurch of the body while hanging to a car strap, showed this deposit in the picture, patients who never previously had any symptoms, but who had the characteristic symptoms after the injury. In one such case, "hyperacute," I operated a few days after the injury. The deposit had been shown by the Roentgen ray three days after the injury. I found a fresh tear in the ecchymosed supraspinatus tendon, and the lime deposit in the tear and in the surrounding bruised tendon tissue. Whether I am right in the assumption of very rapid lime formation, I am willing to leave open. I have not seen rapid disappearance of the deposit. I have seen it occur within two to six months, but not earlier.

I believe that I have fully answered Dr. Wolf's question. Occasionally one encounters metastatic suppuration in the bursa in connection with a septic process; but I believe that the cases of subdeltoid bursitis of which we have been speaking are not infectious in origin. Sometimes a man reports an isolated case in which the patient had tonsillitis previously, and then be jumps to the conclusion that the tonsillitis was the cause of the disease. That is unscientific.

I hope that I have made it clear that these patients often get well without operation.

School Medical Inspection and Local Government.—Were it not for the fact that the Cumberland schools and the county schools are one unit, we might be able to see our way clear to establish medical inspection of schoolchildren, but this cannot be under the present system of one school unit for the entire county. Ample laws now exist that would enable the county school commissioners to establish this inspection, but somehow or other, as with all other advanced movements, some public bodies are slow to comprehend their value. We urge all parents to advocate medical inspection for the sake of their children.—*Health Bulletin*, Cumberland, Md.

THE USE OF BAKERS' YEAST IN DISEASES OF THE SKIN AND OF THE GASTRO-INTESTINAL TRACT *

PHILIP B. HAWK, Ph.D.
FRANK CROZER KNOWLES, M.D.
MARTIN E. REHFUSS, M.D.
PHILADELPHIA
AND
JAMES A. CLARKE, M.D.
NEW YORK

With the Collaboration of Olaf Bergeim, Ph.D., H. Rodell Fishback, M.D., Sc.D., Clarence A. Smith, Ph.D., and Robert A. Lichtenthaeler, M.S.

That yeast possesses curative properties was appreciated in the olden times. Hippocrates recommended its use in leukorrhea, and the monks used it for the treatment of plague. Not until the middle of the nineteenth century, however, did the medical profession look favorably on its use. About that time, it was used successfully in furunculosis, anthrax and diabetes. Later it was shown to be effective in diseases of the skin, suppurative processes, diseases of the respiratory passages, gastro-intestinal diseases, vaginitis, general infectious diseases, etc. In fact, for an interval of many years yeast was used as a curative agent in a long list of widely differing disorders. Then came a reaction, and yeast was used comparatively little by the medical profession during the latter part of the nineteenth century.

TABLE 1.—CLASSIFICATION OF NINETY-ONE DIFFERENT CASES IN WHICH THE YEAST TREATMENT WAS USED

Type of Case	Number
Normal	15
Furunculosis	17
Acne vulgaris	17
Acne rosacea	8
Constipation	10
Gastro-intestinal catarrh	3
Intestinal intoxication	1
Eczemas	5
Arthritis deformans	1
Psoriasis	4
Erythema and urticaria	1
Bronchitis	2
Urethritis	2
Pruritus	1
Folliculitis	1
Conjunctivitis	1
Duodenal ulcer	1
Swollen glands	1
Total	91

In 1899 the researches of Brocq[1] emphasized anew the therapeutic importance of yeast, and from 1900 to 1907 many important contributions were made to the subject of yeast therapy. For the last ten years, however, comparatively little attention has been paid to the use of yeast in medicine.

Owing to the fact that the great majority of the yeast researches have been carried out with brewers' yeast or various dried yeast preparations, and since several investigators have asserted that bakers' yeast was not a satisfactory therapeutic agent, we have thought it of importance to make a comprehensive study of the curative value of ordinary bakers' yeast, since that is the most available kind. In all of our tests we used Fleischmann's Compressed Yeast, as that is the best known and most widely used of bakers' yeasts. The fresh yeast was used in all cases, a new supply being secured from two to three times a week and kept in the refrigerator until used.

TABLE 2.—SUMMARY OF RESULTS IN THE SERIES OF CASES

Condition	Number of Cases	Improved or Cured
Furunculosis	17	16
Acne vulgaris	17	17
Acne rosacea	8	8
Constipation	10	9
Gastro-intestinal catarrh	3	3
Intestinal intoxication	1	1
Eczemas	5	0
Arthritis deformans	1	1
Psoriasis	4	1
Erythema and urticaria	1	1
Bronchitis	2	2
Urethritis	2	2
Pruritus	1	1
Folliculitis	1	1
Conjunctivitis	1	1
Duodenal ulcer	1	1
Swollen glands	1	1
Totals	76	66

The literature of the yeast question is so voluminous that we make no attempt in this connection to give a comprehensive survey of previous work. Our main purpose is to present a brief summary of the cases we have studied. Those who are interested in the literature of the subject we would refer to Lardier,[2] Krause[3] and Hedrich,[4] in whose articles a very full bibliography will be found.

We have made a study of ninety-one cases, which have been classified as explained in Table 1. We made tests on normal persons to learn the action of yeast in the stomach when given suspended in water, beef tea or orange juice, with meals or between meals. We also studied the comparative effect of living and dead yeast. The yeast was killed by treating it with boiling water for a few minutes. All stomach examinations were made by means of the fractional method.[5]

From these tests it is apparent that yeast may be administered satisfactorily either with meals or on the empty stomach. It is also apparent that killed yeast (that is yeast placed in boiling water for a few minutes) acts much the same in the stomach as living yeast. If the patient is troubled with gas formation it is preferable to use killed yeast, or to administer living yeast between meals.

These tests also demonstrated conclusively that yeast is not readily destroyed in the human stomach, but that on the contrary, especially when taken between meals, a large part of the yeast passes into the intestine in the living condition. Hence, it is possible that in certain disorders, especially those involving constipation, the living yeast has a more pronounced action than dead yeast.

From Table 2 it will be seen that yeast treatment gave the best results in furunculosis, acne vulgaris, acne rosacea and constipation. The treatment was also useful in acute bronchitis, urethritis, conjunctivitis, swollen glands, folliculitis, gastro-intestinal catarrh, intestinal intoxication, arthritis deformans and duodenal ulcer. The laxative effect of the yeast was observed in cases other than those of constipation. In fact, in some instances the laxative effect was so pronounced that it was necessary to reduce the dosage. Both the fresh yeast and that killed by boiling water

TABLE 3.—REPORTS OF CASES OF FURUNCULOSIS IN WHICH THE YEAST TREATMENT WAS USED

Case, Sex and Age	Complaint	Treatment	Results
16— F —22	Series of deep-seated boils for over two months; five lanced in one week.	Five injections of vaccine. One-half cake yeast t. i. d. after meals.	No effect. Almost immediate improvement; cure in two weeks.
17— F — *	Several large boils, which did not yield to vaccine. Boil started on leg after yeast was stopped.	Three cakes daily for two weeks. Yeast resumed.	Boils disappeared. Boil soon cured.
18— M —38	Succession of boils; many on back of neck, several on body; one carbuncle.	One-half cake t. i. d. after meals; arsenic internally.	All cleared up; patient has increased in weight.
19— M —42	Disease present several years; six small boils in six weeks.	Three cakes daily before meals for seven days.	Boils cleared quickly.
20— F — *	Large boil draining on face; one just coming to a head.	Three cakes daily before meals for two weeks.	Cured; no more appeared
21— F —26	Boils a week apart for about two months; when treatment started, one on neck and one on wrist.	Three cakes daily before meals for two weeks.	Both healed; no more in four weeks.
22— M —33	Carbuncle treated surgically; later boils developed.	One-half cake t. i. d. after meals.	Cured; eructations and looseness of bowels after yeast.
23— M — *	Boils on buttocks for period of nine months.	Three cakes daily before meals for two weeks.	All boils healed.
24— M — *	Nine large boils during a period of about two years.	Three cakes daily before meals for six weeks.	Felt much better; no recurrence.
25— M —25	Five boils in two months.	Three cakes daily before meals.	Boils soon subsided; no recurrence.
26— M —42	Stye in left eye; boric acid treatment four days with no improvement; patient subject to this trouble.	One-half cake dead yeast t. i. d. before meals next four days.	Cure more rapid than ever before noted.
27— M —20	Boils periodically for several years; large one on right buttock lanced after ten days and yeast treatment started. Two weeks after first boil healed a much smaller one appeared on abdomen.	Three cakes daily before meals for three weeks. Yeast continued.	Healed quickly. Cured quickly; no recurrence after four months.
28— M —25	Troubled with boils for several months; large one on back of neck.	Three cakes daily before meals for three weeks.	Boil disappeared.
29— M —52	Boils periodically for years; two large ones on neck.	Two cakes dead yeast daily.	Boils disappeared.
30— M —24	Troubled with boils at short intervals for several years; large boil in left axilla lanced after one week and yeast treatment started.	Three cakes daily before meals for one month.	Boils cleared rapidly; second small one failed to head; no recurrence in four months.
31— M —36	Boils at intervals for some months; several dozen large ones on different parts of body, usually not more than two or three at a time.	One cake t. i. d. after meals for three weeks.	Boils continued to appear.
32— M —50	For three months had not been free of boils, most of which were of hazel-nut size.	One cake t. i. d. after meals for four weeks.	Boils stopped appearing after one week; no recurrence in six weeks.

* Adult.

TABLE 4.—CASES OF ACNE VULGARIS TREATED WITH YEAST

Case, Sex and Age	Complaint	Treatment	Results
33— M —21	Disease had been present for nearly two years; deep-seated papules and pustules covering practically entire face.	Zinc sulphate and potassium sulphid with laxatives. Above treatment and one cake yeast t. i. d. after meals.	Only very moderate improvement. At end of two weeks lesions almost entirely dried up; at end of four weeks no active lesions; no new spots in two weeks.
34— F —22	Moderate case, chiefly papular type, of two years' duration.	Boric acid locally for some weeks; then one cake t. i. d. for three weeks.	More improvement in ten days with yeast than in one month local applications; no active lesions in one month.
35— M —20	Moderate eruption, mostly papular, during one year.	One cake t. i. d. for three weeks.	Active lesions disappeared.
36— M —23	For four years, a marked case with numerous pustules and papules.	One cake t. i. d. for four weeks; boric acid locally.	Marked improvement.
37— M —25	For five years, numerous deep papules and pustules.	Zinc sulphate and potassium sulphid locally; one cake t. i. d for four weeks.	Marked improvement.
38— F — *	Moderate eruption on face for one year.	Three cakes daily before meals for three weeks.	Marked improvement; face clear when last seen some weeks later.
39— M —42	Slight eruption on back and abdomen for about one month.	One-half cake dead yeast t. i. d. before meals for seven days.	Eruption disappeared.
40— M —21	Moderate eruption for two months.	Three cakes daily before meals for two weeks.	Eruption cleared.
41— M —19	Numerous pustules and papules on face and body for five years.	Three cakes daily before meals for three months.	Improvement rapid; marked improvement after three months.
42— M —20	Acute eruption.	Three cakes daily for two weeks.	Eruption disappeared; no recurrence.
43— M —21	Pronounced case of five years' duration.	Two cakes daily for four weeks.	Eruption cleared; began to return one month later.
44— M —23	Marked eruption on face and body for three years.	Two cakes daily for four weeks.	Eruption disappeared, but returned one week after yeast was discontinued.
45— M —21	Very moderate eruption on cheeks and chin for one month.	Three cakes daily for four weeks.	Eruption disappeared.
46— M —22	Moderate eruption on cheeks for two months.	Three cakes dead yeast t. i. d. before meals for two weeks.	Eruption entirely disappeared.
47— M —24	Moderate eruption, chiefly papular, during several years.	Three cakes daily before meals for two months.	Eruption disappeared in two weeks; no recurrence.
48— M —21	Moderate eruption on face and body during three years.	Two cakes daily before meals for five weeks.	Cleared almost completely in four weeks.
49— M —20	Case of long standing with some indurated follicles; local sulphur treatment had yielded no results.	One-half cake t. i. d. after meals.	Unquestioned improvement; no other medication or change of diet.

* Adult.

TABLE 5.—RESULTS OF YEAST TREATMENT IN ACNE ROSACEA

Case, Sex and Age	Complaint	Treatment	Results
50— M —50	Typically marked case of fifteen years' duration; numerous large red papules, congested arterioles, and bright red nose.	One cake yeast t. i. d. after meals for four weeks.	Improvement in few days; nose and cheeks normal in color in four weeks except for arterioles; papules gone.
51— M —45	Marked case of ten years' duration; numerous bright red, deep-seated papules; scarlet nose, cheeks and forehead.	Boric acid locally; one cake yeast t. i. d. after meals for four weeks.	Lesions cleared; redness disappeared in three weeks; unusually quick result.
52— F —40	Marked case of five years' duration; chiefly papules with considerable congestion of nose and face.	Boric acid locally; one cake t. i. d. after meals for three weeks.	Improved in a few days; practically cleared in ten days.
53— M —35	Moderate case of three years' duration.	One cake t. i. d. after meals for two weeks.	Skin normal and lesions gone in two weeks.
54— F —30	Moderate case of two years' duration; typical papules, congestion, and few pustules.	One cake t. i. d. after meals for three weeks.	Face cleared in less than two weeks.
55— M —35	Moderate case of three years' duration; typical papules, a few pustules, bright red nose, cheeks and forehead.	One cake t. i. d. after meals for three weeks.	Lesions cleared in two weeks' time.
56— F —38	Marked case of eight years' duration; numerous papules and pustules, scarlet nose, red cheeks and forehead.	Boric acid locally; one cake t. i. d. after meals for four weeks.	Markedly improved.
57— M —52	Bright red nose for several years.	Two cakes daily for four weeks; living yeast at first, dead yeast later.	Marked improvement.

TABLE 6.—THE SUCCESS OF YEAST TREATMENT IN CONTROLLING CONSTIPATION

Case, Sex and Age	Complaint	Treatment	Results
58— F —46	Slight constipation for a few weeks.	One-half cake dead yeast t. i. d. before meals for one week.	Movements so frequent yeast was discontinued.
59— F —26	Mild case of chronic constipation of several years' duration.	One-half cake dead yeast t. i. d. for ten days.	Much improvement.
60— M —48	Chronic constipation for a year or more; receiving three compound cathartic pills daily to regulate bowels.	Three cakes yeast daily before meals.	Movements became regular without other medication.
61— M —52	Mild constipation for several years.	Two cakes daily before breakfast and dinner for four weeks.	Living yeast regulated well, killed yeast did not.
62— M —21	Slight constipation for a few weeks.	Two cakes daily before meals for a month.	Regular movements from the start of yeast.
63— M —24	Constipation for several months.	Three cakes daily before meals.	Regular movements soon occurred.
64— M —21	Mild constipation.	Two cakes daily for five weeks.	Regular movements soon and remained so after yeast was discontinued.
65— F —69	Constipation for several years.	Three cakes daily for several days.	Regular movements in two or three days.
66— M —20	Constipation for several years with periodic headache.	Three cakes daily before meals.	Regular in four or five days; general physical condition improved.
67— F — *	Subacute appendicitis, high intestinal stasis, and constipation.	Yeast and dietary measures.	No relief from constipation; appendiceal condition worse.

* Adult.

showed laxative power. In one case the patient became constipated under yeast treatment.

So far as gastro-intestinal conditions are concerned, it is apparent that yeast has its greatest usefulness in conditions accompanied by cutaneous manifestations. It seems to us that yeast is essentially indicated in chronic nonobstructive bowel conditions and contraindicated in the acute conditions.

Whether the success of yeast in acne vulgaris and acne rosacea is due alone to its laxative action or to some fixed effect on the intestinal tract, we are unable to say. The preparation was laxative in all these cases, in two so much so that a half dose was given for a few days. There was considerable gas formation, but no complaints were made on this score.

In furunculosis, yeast is a remarkably efficacious remedy. Its curative action in these cases is no doubt aided by the leukocytosis which is developed.

TABLE 7.—CASES OF GASTRO-INTESTINAL CATARRH TREATED WITH YEAST

Case, Sex and Age	Complaint	Treatment	Results
68— F — *.....	Chronic gastro-intestinal catarrh, stubborn, and of several years' duration.	Lavage, applications of silver, dietary measures, *one-half cake yeast t. i. d.*	Bowel condition improved; slight increase in gastric hydrochloric acid.
69— M —35.....	Ethmoidal sinus disease, gastric and intestinal catarrh, intestinal stasis, and constipation.	Low protein diet, magnesium perhydrol, nose and throat treatment; *one-half cake at first, then one-quarter cake t. i. d.*	Bowel condition improved; catarrhal tendency lessened; movements more complete.
70— M — *.....	Chronic gastric catarrh, low grade catarrh of the colon, chronic constipation, and tinnitus aurium.	Dietary and local treatment gave improvement; *one-half cake t. i. d.* added.	Definite improvement in ringing of ears and bowel condition.

* Adult.

TABLE 8.—YEAST TREATMENT IN FIVE CASES OF ECZEMA

Case, Sex and Age	Complaint	Treatment	Results
71— M —35.....	All five were extensive, long standing cases, papular, papulo-vesicular, vesicular, or rubrum in type.	Petrolatum locally with *three cakes of yeast daily* was the treatment in all of these cases.	No improvement although yeast was given in some cases for four months.
72— F —30.....			
73— M —45.....			
74— F —40.....			
75— M —48.....			

TABLE 9.—RESULTS OF YEAST THERAPY IN THE TREATMENT OF PSORIASIS

Case, Sex and Age	Complaint	Treatment	Results
76— M —12.....	Typical case of two years' duration; general distribution with lesions mostly the size of a dime.	One-half cake t. i. d. and petrolatum locally; previous petrolatum and arsenic treatment had little effect.	Very marked improvement.
77— M —50.....	Very marked case of eight years' duration; large plaques, some palm-sized, were present.	One cake t. i. d., and petrolatum locally.	No improvement.
78— M —40.....	Very marked case of six years' duration; large plaques with very thick patches.	One cake t. i. d. for three weeks; petrolatum locally.	No improvement.
79— F —30.....	Moderate case of five years' duration.	Three cakes daily for three weeks; petrolatum locally.	No improvement.

TABLE 10.—REPORTS OF MISCELLANEOUS CASES IN WHICH THE YEAST TREATMENT WAS USED

Case, Sex and Age	Complaint	Treatment	Results
80— F —13.....	Acute bronchitis.	One-half cake dead yeast t. i. d. for seven days.	Marked improvement.
81— F —27.....	Acute bronchitis.	One-half cake dead yeast t. i. d. for one week.	Marked improvement.
82— M —28.....	Mild case of urethritis of three months' duration.	Three cakes daily for three weeks.	Marked improvement.
83— M —26.....	Mild case of urethritis of one month duration.	Three cakes daily for three weeks.	Condition cleared up.
84— F —30.....	Long standing case of arthritis deformans, with marked intestinal stasis and obstinate constipation. Frequent acute exacerbations with redness and swelling of joints.	Ductless gland therapy, intestinal irrigations, B. coli vaccine, etc., for years. One-half cake yeast t. i. d. after meals.	Not much effect. Acute exacerbations disappeared.
85— M —19.....	Enlarged liver, high intestinal stasis, hyperacidity, hypersecretion, gastric motor delay, and marked intestinal putrefaction.	Three cakes daily after meals.	No relief.
86— F —46.....	Pronounced conjunctivitis of the right eye.	One-half cake dead yeast t. i. d. for seven days.	Eye became normal.
87— M —22.....	Folliculitis; hundreds of hair follicles from ankles to knees much inflamed; two months' duration.	Three cakes daily and petrolatum locally for three weeks.	Cured in two weeks; no recurrence after one month.
88— M —50.....	Pruritus with generalized itching of two years' duration; patient neurotic.	One cake t. i. d. for three weeks.	No improvement.
89— M — 9.....	Swollen superficial cervical lymph glands.	One-quarter cake dead yeast t. i. d. in orange juice for eight days.	Glands became normal.
90— F — *.....	Erythema and transient urticaria.	One-quarter cake t. i. d. after meals.	Unquestionable improvement and pronounced laxative action.
91— M — *.....	Medical diagnosis of duodenal ulcer with gastric hypermotility.	Frequent feedings; one-half cake t. i. d. after the three main meals; bromids, atropin and alkalies.	Symptoms disappeared and bowels made regular.

* Adult.

SUMMARY

1. Bakers' yeast was found to be a useful remedy in the treatment of furunculosis, acne vulgaries, acne rosacea, constipation and in certain other cutaneous and gastro-intestinal conditions

2. The conditions which respond most favorably to the yeast treatment were (*a*) furunculosis, (*b*) the acnes (vulgaris and rosacea), and (*c*) constipation. Of seventeen cases of furunculosis, all but one of the patients were improved or cured. Of seventeen cases of acne vulgaris, all patients were improved or cured. Of eight cases of acne rosacea, all patients were improved or cured. Of ten cases of constipation, nine were improved or cured. In other words, fifty out of fifty-two cases of furunculosis, the acnes, and constipation were improved or cured by yeast treatment.

3. We consider that yeast is fully as successful as any other remedy in furunculosis, acne vulgaris and acne rosacea.

4. In many of the cases which came under our observation, the yeast treatment caused an improvement in the general physical condition of the patient quite unassociated with the improvement of the symptoms associated with the particular disease in question.

SPECIFIC SERUM THERAPY OF EPIDEMIC POLIOMYELITIS

A REPORT ON ONE HUNDRED AND FIFTY-NINE CASES TREATED WITH ANTIPOLIOMYELITIC HORSE SERUM *

JOHN W. NUZUM, M.D.
AND
RALPH G. WILLY, M.D.
CHICAGO

This report describes in detail the mode of production, technic of administration and the results obtained in a series of 159 cases of epidemic poliomyelitis treated with antipoliomyelitic serum prepared in the horse by injections of the poliomyelitic coccus. These patients were treated in the Cook County Hospital during the present epidemic which has prevailed throughout the summer and autumn months of 1917 in the city of Chicago.

The epidemic first appeared during the latter part of July, 1917. It may be said to have reached its height during the first twenty days of September, when more than 200 cases were reported to the health department and over 100 patients were admitted to the isolation ward of the Cook County Hospital. With the advent of cool weather the number of daily admissions appears to be decreasing somewhat, and accordingly it now seems pertinent to report the results attained up to October 1 of the present year.

We have been fortunate, indeed, in having the opportunity to study two different outbreaks of infantile paralysis. The first epidemic visited Chicago during the summer of 1916, when there were 285 cases reported with a mortality of 15 per cent. The present epidemic of 1917 has already exceeded the first both as regards the total number of cases reported and more especially the extreme virulence of the causative micro-organism and the unusually high death rate. From statistics kindly furnished by the Chicago Health Department, 301 cases of poliomyelitis have been reported during the period of July 20 to Oct. 1, 1917, with a mortality of 32 per cent. The majority of deaths have occurred in those cases of an ascending or Landry's type of paralysis with progressive involvement of the diaphragm, intercostal and accessory muscles of respiration. It should be mentioned that in a considerable number of patients the disease has terminated fatally within from twenty-four to forty-eight hours after the onset of the symptoms, and not a few patients have died in the ambulances en route to the hospital.

The detection of neutralizing substances in the blood serum of both monkeys and human beings[1] following an attack of poliomyelitis, and the observations of Flexner and Lewis[2] of the protection of inoculated monkeys by means of injections of serum of recovered monkeys and human beings apparently has furnished the basis for serum therapy in man. Netter[3] and more recently several others have reported favorably on the treatment of poliomyelitis in man by injections of immune serum from convalescent patients. Unfortunately, however, it would seem that there are several disadvantages attendant on this method. Chief among these is the difficulty in securing serum in sufficient quantity properly to treat any considerable number of patients, and what is of still greater importance, the probable low antibody content of human serum as compared with an immune serum produced in the horse by injections of the causative micro-organism. The independent observations of Mathers,[4] Rosenow[5] and Nuzum and Herzog[6] on the presence of a peculiar gram-positive coccus in the central nervous system of poliomyelitic patients was soon followed by the isolation of the same coccus from the spinal fluid[7] of patients during the early stages of poliomyelitis. An intensive bacteriologic study of the spinal fluid of poliomyelitic patients during the present epidemic has served to confirm with striking regularity the presence of the same micrococcus. Thus in 128 cases the coccus has been isolated in pure culture in 109, or 85 per cent.; in ten, or 8 per cent., *B. subtilis* was present as a contamination, and nine cases, or 7 per cent., remained sterile. In many cases repeated punctures on successive days have yielded pure cultures of the coccus. Cultures are obtained with ease by inoculating a 1 per cent. glucose broth medium with from 1 to 2 c.c. of freshly drawn spinal fluid, and incubating under aerobic conditions for from twenty-four to forty-eight hours. Initial cultures on solid mediums are difficult to obtain. The majority of these different strains have been identified in subcultures on human blood agar-plates as fine, pin point, slightly green colonies often surrounded by a hazy zone of hemolysis. Moreover, we have found it possible to identify the coccus by the use of immune horse serum, employing the dilution method for estimating the point of opsonic extinction. This reaction is specific for the poliomyelitic coccus. Finally, we have recently shown, as has Rosenow,[8] independently, that repeated intravenous injections of the coccus in the horse produce an immune serum rich in agglutinins, complement fixation bodies and especially opsonin, and such a serum has been shown to possess protective and curative properties against fatal doses of virulent virus in experimental poliomyelitis in monkeys.

On the basis of these results it becomes a matter of the greatest moment to determine the therapeutic efficiency of such an immune serum in acute poliomyelitis in man.

IMMUNIZATION OF HORSE

A large horse, 6 years old, weighing 1,400 pounds, was selected and immunized, at first, according to the method described by Amoss and Wollstein,[9] which we previously empolyed to produce an antipoliomyelitic serum in sheep. The horse received intravenous injections of living organisms in increasing doses on three successive days, followed by periods of rest of from seven to ten days. For the first injection the twenty-four hour growth on a glucose agar slant was suspended in 2 c.c. of sterile physiologic sodium chlorid solution, and 0.3 c.c. of this suspension in 10 c.c. of saline solution was injected intravenously. Twenty-four hours later, 0.5 c.c. of the foregoing suspension of bacteria in 10 c.c. of physiologic sodium chlorid solution were injected intravenously, and a similar dose was given on the third day. This was followed by a period of rest, when a second series of injections was instituted. Small desensitizing doses have been regularly employed during the first injection of each series, and after the lapse of an hour the full dose is given. The organisms injected have all been originally cultivated in 1 per cent. glucose broth, and later subcultures were made on glucose agar slants and incubated at 35 C. for from eighteen to twenty-four hours. All of the strains employed for immunization have been subcultivated through several generations, always under aerobic conditions, and each strain injected has regularly been plated on blood agar prior to injection into the horse.

The first serial injections were begun, Jan. 30, 1917, and consisted of the poliomyelitic coccus isolated from the brain and cords of two recent human patients. The following six serial injections contained strains isolated from the spinal cord and the central nervous system of six fatal cases of human poliomyelitis, all of which were confirmed by necropsy and by microscopic sections of the spinal cord. The next seven serial injections consisted chiefly of the coccus isolated from the central nervous system of five different monkeys recently paralyzed with virus. Injections of bacteria were given usually intravenously but also by intramuscular injections and subcutaneously into the neck, shoulder and buttocks of the horse. The maximum dose has consisted of the twenty-four hour surface growth of three glucose agar slants in 8 ounce nursing bottles. Regular serial injections of both human and monkey coccus were continued up to July 1, 1917. A test bleeding made, June 6, revealed a potent immune serum. At this time 5,000 units of tetanus antitoxin were injected subcutaneously into the left buttock of the horse. From July 1 to September 15 a mixed culture of ten different strains of the coccus recently isolated from the spinal fluid of patients has been injected intravenously according to the schedule of serial injections followed above. The horse has been bled as follows: June 6, 500 c.c.; July 11, 2,000 c.c.; July 28, 2,000 c.c.; August 8, 3,500 c.c.; August 23, 2,500 c.c., and September 14, 3,600 c.c.

PREPARATION OF SERUM

After serial injections with different strains of the coccus over a period of four months according to the method outlined above, the horse was bled, June 6, and the antibody content of the serum determined. With the employment of homologous strains of the coccus, agglutination was found to be complete at 1:5,000 dilution, while the point of opsonic extinction as estimated by the dilution method of Klein was 1:6,144. From ten to fourteen days after the last injection the horse was bled from the jugular vein and the blood collected in sterile flasks under aseptic conditions. The blood was allowed to clot, at first at room temperature, and later the flasks were placed in the ice box for from twenty-four to forty-eight hours. The serum was decanted and centrifuged in sterile rubber capped containers. After repeated cultural tests for sterility the clear hemoglobin-free serum is bottled in sterile flasks of 2 ounces capacity plugged with rubber stoppers and sealed with paraffin. The serum for intraspinal administration is preserved in glass containers similar to those utilized in the preservation of antimeningococcic serum.

The serum employed by us has been used unactivated and unpreserved. The addition of 0.2 per cent. tricresol as a preservative has in our experience given rise to rather severe reactions in two patients and been found to aggravate the local irritant effect. It is highly essential that only serum free from hemoglobin be employed, as its presence definitely increases the irritative effect. Regarding the duration of potency of the serum, it has been found that the antibody content as determined by opsonic extinction and agglutination tests of a specimen preserved in the ice box has thus far remained unaltered over a period of three months.

METHOD OF ADMINISTRATION

All of the patients have been treated with serum both by intraspinal injections and at the same time by intravenous administrations. A considerable number have also received intramuscular injections. Intraspinal injections of from 5 to 15 c.c. were given slowly by the gravity method after the previous withdrawal of an equal or greater amount of spinal fluid. It is well known that in poliomyelitis the lumen of the blood vessels is constricted by the encircling ring of mononeuclear lymphocytes—the so-called perivascular infiltration. Accordingly it would appear that the amount of serum which can be safely injected intraspinally in children without danger of producing further injury to the brain stem must be small. At the same time it seems highly desirable to inject larger amounts intravenously in order to effect as rapid a neutralization of the virus as possible. In young children, in whom the median basilic vein is too small to find, we have regularly turned the head to one side; and if pressure is made with the finger just above the clavicle, the external jugular vein stands out very prominently even in infants, and can be readily entered by the needle. From 15 to 30 c.c. of serum are slowly injected intravenously.

CLINICAL PICTURE FOLLOWING SERUM THERAPY

In many of the acute cases the administration of serum has been followed by a critical fall in the temperature occurring from twelve to thirty-six hours;

---

[9] Amos, H. L., and Wollstein, Martha: A Method for the Rapid Preparation of Antimeningitis Serum, Jour. Exper. Med., 1916, 23, 403.

after injection. Coincident with this there is a slowing of the pulse rate and definite clinical evidence of general improvement. The initial rise in the temperature usually attributed to the injection of human serum has occurred in only a very few cases. When the temperature has remained high we have repeated the intravenous injection in a few patients within twelve hours after the first treatment. It has seemed to us that the temperature may well serve as a guide to the optimum dosage of serum. Serum reactions have occurred in approximately one third of our cases usually from five to eight days after injection, and manifest themselves as an urticaria which disappears within from twenty-four to forty-eight hours. These have always rapidly disappeared, and beyond the transient discomfort to the patient, have appeared of little consequence.

ANALYSIS OF CASE HISTORIES

During the latter part of the Chicago epidemic of 1916, one of us (J. W. N.) first treated a small series of ten cases of typical poliomyelitis by intraspinal and intravenous injections of the immune serum produced by injections of the poliomyelitic coccus in the sheep. The first patient was treated, Dec. 29, 1916.[10] Ten patients in all were treated, with one death. Two patients who received early treatment recovered completely and warrant brief consideration:

CASE 1.—G. S., girl, aged 8 years, Dec. 27, 1916, had headache and vomited. December 28, there was weakness of both legs. December 29, she was admitted to the hospital, with temperature of 99.6 F. She was stuporous. The pupils were dilated and unequal. The right leg was flaccid, and the patellar jerk was absent. The left leg was weak. There was paralysis of the urinary bladder, and incontinence of both urine and feces. The bladder was distended to the level of the umbilicus.

December 29, 15 c.c. of immune serum were injected intraspinally and 20 c.c. serum intravenously. January 6, the child appeared bright and took nourishment. Twenty c.c. of serum were injected intravenously, January 9. The bladder and the bowels were acting. The paralysis never progressed, and after a sojourn of five weeks in the hospital the patient was discharged with a complete return of function of both legs.

CASE 2.—Mrs. B., aged 25, March 1, 1917, had headache, coryza and drowsiness. March 4, she was unable to move her legs. There was incontinence of urine and feces. March 5, she was admitted to the hospital. There was flaccid paralysis of both legs, with loss of Achilles and knee jerks. The bladder was distended with urine. There was apparent weakness of both hands. There was bilateral ptosis. The cerebrospinal fluid was clear, with 85 cells per cubic millimeter and positive globulin tests. March 6, 15 c.c. of serum were injected intraspinally and 20 c.c. intravenously. March 8, 25 c.c. of spinal fluid were withdrawn and 15 c.c. of serum injected intraspinally. March 9, the temperature was normal and there had been no spread of the paralysis. March 14, the patient talked irrationally and complained of difficulty in seeing objects. March 20, a plaster cast was applied to the legs by Dr. Parker.

The patient made a complete recovery, and walked out of the hospital, April 12, 1917. She has been examined on two subsequent occasions, and has regained her tendon reflexes and apparently complete function of her legs.

The foregoing cases served to emphasize the possible value of serum therapy and the importance of early administration of serum. The first patient was treated within forty-eight hours after definite symptoms of meningeal invasion. The second patient came under treatment at a later date when the paralysis was marked and rather disseminated over the cerebrospinal axis. Both patients received repeated injections of serum intravenously and intraspinally, and both made a good recovery.

During the present epidemic of 1917 and up to October 1, we have treated a total of 159 patients. During the same period, 250 patients have been admitted to the isolation wards of the Cook County Hospital on the services of Drs. Francis, Hoyne, Blatt and Irish, to whom we are indebted for the opportunity to treat and study these patients. All patients have been admitted in rotation to the services of these different attending physicians, and all patients admitted on one of these services have served as controls so far as they have not been treated with immune serum. The observation was made early in the course of serum therapy that patients with respiratory paralysis represent the end-picture in infantile paralysis and are not benefited either by serum therapy or by any other known treatment. Seven patients with typical respiratory paralysis have been given serum as a last resort without any apparent beneficial effects. These seven patients have been included in our total number of nineteen deaths in cases in which the patients received serum therapy. More recently we have not treated patients exhibiting an advanced respiratory paralysis at the time of admission to the hospital. With this possible exception there has been no selection of cases for serum treatment.

We have thus far treated 159 patients admitted to the Cook County Hospital in all stages of infantile paralysis. Of these 159 cases, nineteen patients have died, giving a mortality rate of 11.9 per cent. Excluding seven patients admitted to the hospital with advanced respiratory paralysis and dying within a short time after admission, to whom serum was given as a last resort, we have twelve deaths with a mortality rate of 7.5 per cent. At first glance these figures are in striking contrast to the total number of 100 patients admitted to the hospital during the same period of time and not receiving serum therapy. Of these 100 patients, thirty-eight died, a mortality rate of 38 per cent. However, it must be stated in all fairness that of these 100 untreated cases, twenty-five patients had an advanced respiratory paralysis on admission.

MORTALITY IN PATIENTS TREATED WITH SERUM IN THE COOK COUNTY HOSPITAL AS COMPARED WITH UNTREATED CASES FROM JULY 20 TO OCT. 1, 1917

	Total Cases	Deaths	Mortality, Per Cent.
Untreated cases	301	97	32
Serum treated cases	152	12	7.5

The mortality rate of a series of serum treated cases as compared with a series of untreated cases occurring during the same period of time and during the same epidemic of 1917.

For purposes of analysis and comparison we have divided the patients treated with serum into two groups. Group 1 comprises a series of fourteen cases in which no definite paralysis could be detected at the time serum treatment was instituted. This group has been further subdivided into Class 1, comprising ten typical preparalytic cases in all of which the history, clinical examination and spinal fluid findings were positive for poliomyelitis, and Class 2, consisting of four patients presenting the clinical picture of the meningeal or encephalitic type of the disease, namely, rigid neck, opisthotonos, stupor, muscular twitchings, spastic extremities, etc. Group 2 comprises a series of 141 patients, all exhibiting varying degrees of paralysis at the time of treatment. This group has for convenience been subdivided into Class 1, composed of patients in whom the paralysis appeared to be spreading, and Class 2, consisting of patients with definite paralysis of varying duration. Brief summaries are given of instructive case histories illustrating the various group divisions:

---

[10] A brief preliminary report of the results attained appeared in the Bulletin of the Chicago Medical Society, April 21, 1917.

GROUP 1. NO PARALYSIS AT THE TIME OF TREATMENT (TEN CASES)

Class 1. Preparalytic Cases

Case 98.—Boy, aged 18 months, Sept. 17, 1917, had fever and showed irritability. September 18, he complained of pain in the legs when made to stand. September 19, he was admitted to the hospital. The temperature was 101.4, the pulse 120, and respirations 26. The cerebrospinal fluid revealed 120 cells per cubic millimeter. Globulin tests were positive. No paralysis was detected. September 19, at 2 p. m., 5 c.c. of serum were injected intraspinally and 15 c.c. intravenously. September 20, the temperature was normal and no paralysis ever developed.

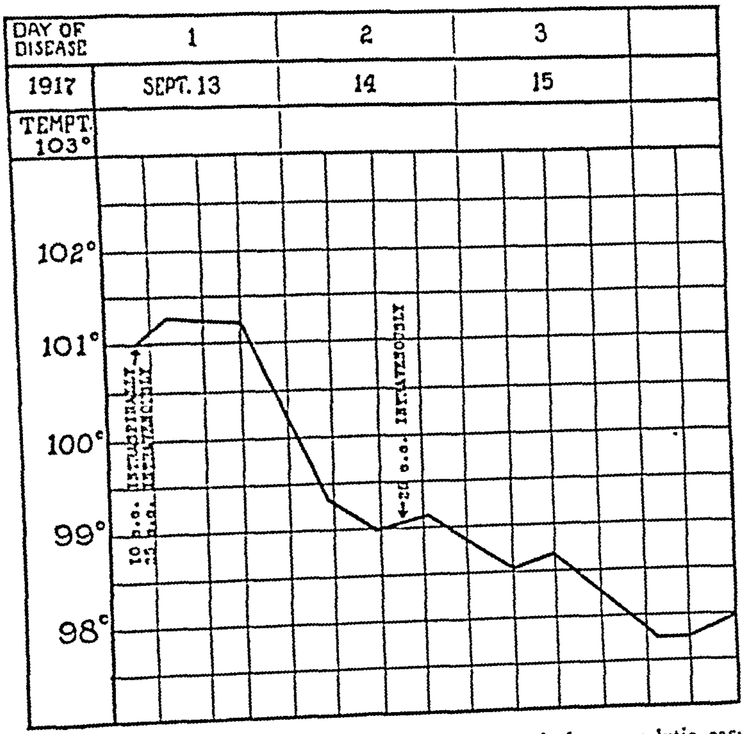

Chart 1 (Case 79).—Temperature curve in a typical preparalytic case of poliomyelitis in which the patient developed a transitory right sided facial paresis thirty-six hours after the first injection of serum. This patient made a complete recovery.

Serum was given forty-eight hours after the first symptoms, and the temperature fell from 101.4 to normal within twenty-four hours and paralysis never developed.

Case 79.—Boy, aged 3 years, Sept. 13, 1917, was brought to the hospital by the mother, who stated that the patient complained of headache, pains in the legs and the back of the neck, and felt too sick to get out of bed that morning. On admission the temperature was 101. The spine sign was positive. The cerebrospinal fluid revealed 27 cells per cubic millimeter. Globulins were + + +. No paralysis was detected. September 13, 10 c.c. of serum were injected intraspinally and 25 c.c. of serum intravenously. September 14, the temperature was 99.2. Twenty-five c.c. of serum were injected intravenously. September 15, the temperature was normal. September 18, a definite right sided facial paresis had appeared, which, however, was transitory, and the patient recovered completely.

This patient received serum within twelve hours after the first symptoms appeared. The interesting feature of this case is the appearance of a facial paresis five days later, which lasted only two days, and recovery was uneventful.

Case 13.—Girl, aged 3 years, Aug. 15, 1917, on admission to the hospital, had a temperature of 101; the pulse was 120, the respirations, 22. There were fine twitchings of the muscles of the entire body. There was left sided facial paresis, with ptosis of the left upper eyelid and drooping of the left corner of the mouth. No paralysis was detected. The cerebrospinal fluid was clear, with 59 lymphocytes. The globulin was increased. August 15, 10 c.c. of serum were injected intraspinally and 18 c.c. intravenously. August 16, the temperature was normal. Ten c.c. of serum were injected intraspinally. Recovery was complete.

Case 46.—Girl, aged 6 months, Sept. 2, 1917, had fever and vomited. September 4, the child was drowsy and irritable. September 5, she was admitted to the hospital. The temperature was 99.6, the cerebrospinal fluid, 170 cells per cubic millimeter. The globulin was + + +. No paralysis was detected. Ten c.c. of serum were injected intravenously. September 8, 10 c.c. of serum were injected intravenously. The temperature was normal the following day, and paralysis never developed.

Case 17.—Girl, aged 10 months, Sept. 18, 1917, was admitted to the hospital with a history of fever and vomiting two days before. The temperature was 99, the pulse, 120, and respirations, 26. No definite paralysis was present, but the right arm and shoulder appeared paretic. The cerebrospinal fluid revealed 42 lymphocytes per cubic millimeter. The globulin test was + + +. September 18, 12 c.c. of serum were injected intravenously. The weakness of the right arm and deltoid rapidly disappeared, and recovery was uneventful.

Ten patients, all undoubted instances of preparalytic poliomyelitis, have been treated with immune serum in the early stages of the disease, with prevention of paralysis and complete recovery in 100 per cent. Whether or not paralysis would have developed in all of these patients without serum treatment cannot be determined. As to the apparent advantage of the early administration of serum, there can be no doubt.

Class 2. Meningeal Type (Four Cases)

Case 30.—Girl, aged 22 months, Aug. 24, 1917, was admitted to the hospital. No history of the duration of the illness was available. The temperature was 101.6. The child was extremely rigid and stuporous. There were involuntary twitchings of the arms and hands. The legs were spastic. There was marked tremor of the neck and face muscles. No paralysis was detected. The cerebrospinal fluid was clear; pressure was markedly increased, and there were 154 cells per cubic millimeter, with globulins increased. August 25, 20 c.c. of serum were injected intravenously. August 26, the temperature was 101. Five c.c. of serum were injected intraspinally and 15 c.c. intravenously. The temperature reached

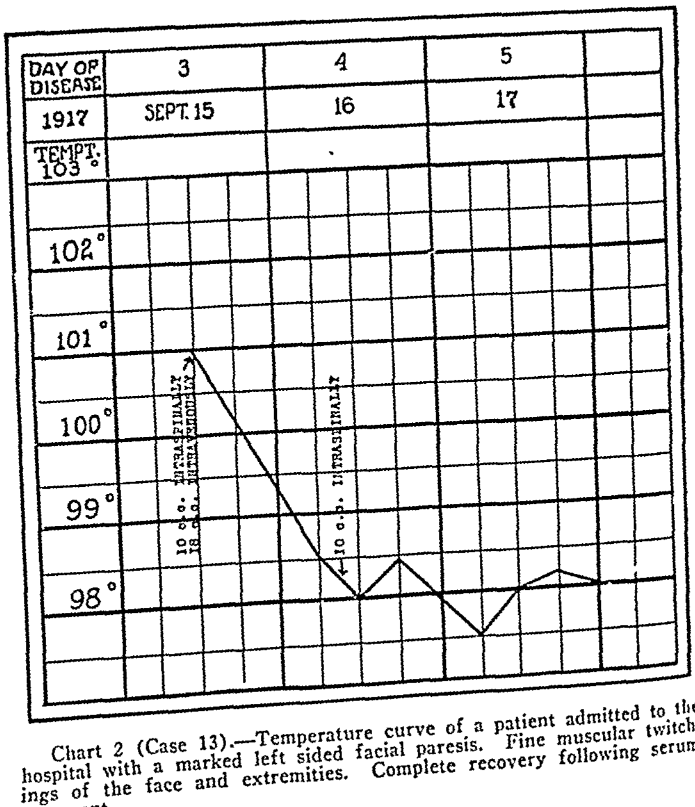

Chart 2 (Case 13).—Temperature curve of a patient admitted to the hospital with a marked left sided facial paresis. Fine muscular twitchings of the face and extremities. Complete recovery following serum treatment.

normal within forty-eight hours, stupor and rigidity of muscles disappeared, and the patient made a complete recovery.

CASE 36.—Boy, aged 3 years, Aug. 30, 1917, was admitted to the hospital. Illness began five days before. The patient lay quiet on the bed, the head retracted and rigid, with marked spasticity of both arms and legs. The reflexes were exaggerated. No paralysis was detected. He cried out when the chin was flexed on the abdomen. The cerebrospinal fluid was clear and contained 320 cells per cubic millimeter, with positive globulin tests. August 30, 5 c.c. of serum were injected intraspinally and 12 c.c. intravenously. August 31, 6 c.c. of serum were injected intraspinally and 15 c.c. intravenously. The patient made a complete recovery.

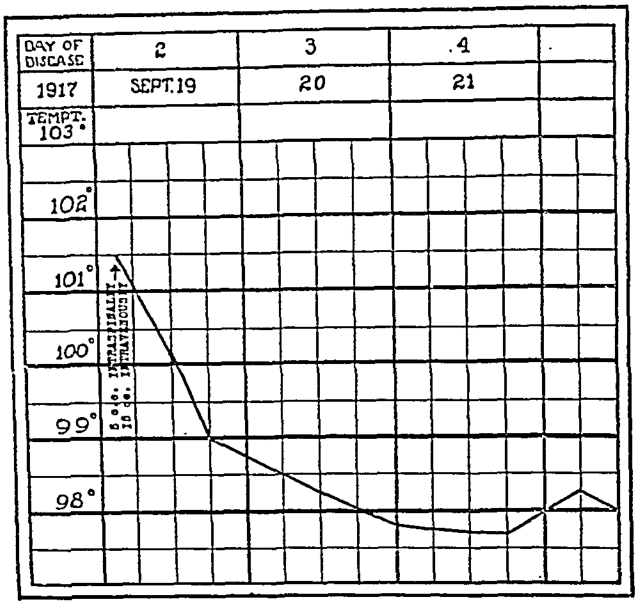

Chart 3 (Case 98).—Temperature curve in a typical preparalytic case of poliomyelitis. Spinal fluid contained 120 cells per cubic millimeter with positive globulin tests. Serum injected thirty-six hours after onset of fever and pain in legs. Note the critical fall of the temperature, with rapid and complete recovery.

The foregoing cases are instructive in that they simulate the clinical picture of meningitis. The disease expends its greatest insult on the upper motor neuron, and the mortality of this type of cases is high. We have treated four meningeal types of poliomyelitis with one death, a recovery rate of 75 per cent.

GROUP 2. CASES SHOWING PARALYSIS AT TIME OF TREATMENT

CLASS 1. PARALYSIS EXTENDING

CASE 26.—Boy, aged 5 years, Aug. 21, 1917, was admitted to the hospital with a history of onset two days previously and the condition growing worse. The child was acutely ill. He could not move head or arms. There was paralysis of the sternocleidomastoid muscles. The head fell backward when the patient was lifted by the arms. There was flaccid paralysis of both arms, and the patient could move the fingers only slightly. The temperature was 100. The cerebrospinal fluid revealed 33 cells per cubic millimeter. The globulin was + + +. August 21, 10 c.c. of immune serum were injected intraspinally and 25 c.c. of serum intravenously. August 22, the respirations were embarrassed. There was slight cyanosis. Ten c.c. of serum were injected intravenously, 5 c.c. intraspinally, and 10 c.c. intramuscularly. August 23, the child was given 20 c.c. of serum intramuscularly. The patient regained good use of the left arm and hand, but the paralysis of the neck, muscles and right arm remained unchanged.

This case is interesting because the location and extent of the paralysis were against the patient's chances for recovery. The early convalescence was stormy, and at one time it was thought that the child had developed a respiratory paralysis. He was given a total of 80 c.c. of serum, and recovered, with good use of the left arm. Whether or not the serum prevented a fatal respiratory paralysis cannot be determined; but we do know that this class of untreated cases has been attended by a high mortality.

CASE 28.—In a girl, aged 6 years, the illness began Aug. 18, 1917, with a convulsion followed by pains in the legs and the back of the neck. August 23, there was weakness of the right leg, and the child became stuporous. August 24, she was admitted to the hospital with the tentative diagnosis of epidemic meningitis. The temperature was 101, the pulse, 128, and respirations, 30. The child was stuporous, and there was flaccid paralysis of both legs. The neck muscles were paretic. The spinal fluid was clear and contained 171 cells per cubic millimeter. The globulin test was + + +. August 24, 10 c.c. of serum were injected intraspinally and 20 c.c. intravenously. August 25, the temperature was 99. The stupor was gone. General improvement was noted. Eighteen c.c. of serum were given intravenously. The temperature reached normal twelve hours after the second injection of serum. The patient was discharged from the hospital, September 24, with paralysis of the legs but slightly improved.

Whether the prompt subsidence of the stupor and the critical drop in temperature can be ascribed to the serum treatment cannot be definitely determined. The paralysis did not progress.

CASE 3.—The onset in a girl, aged 2 years, occurred, July 26, 1917, with headache, fever and vomiting. July 28, there was flaccid paralysis of both lower extremities with weakness of the neck muscles and paresis of both arms. July 29, when she was admitted to the hospital, the temperature was 103, the pulse, 150, and respirations, 60. There was flaccid paralysis of both lower and upper extremities. There was beginning respiratory involvement. The spinal fluid revealed 47 cells per cubic millimeter. Ten c.c. of serum were injected intraspinally after previous withdrawal of 15 c.c. of spinal fluid. July 30, the temperature was 100. The patient had developed a marked respiratory and facial paresis. Spinal puncture was performed and 15 c.c. of fluid withdrawn slowly. Five c.c. of serum were injected intraspinally and 5 c.c. intravenously. July 31, the temperature was 103, the pulse, 174, and respirations, 64. The child died.

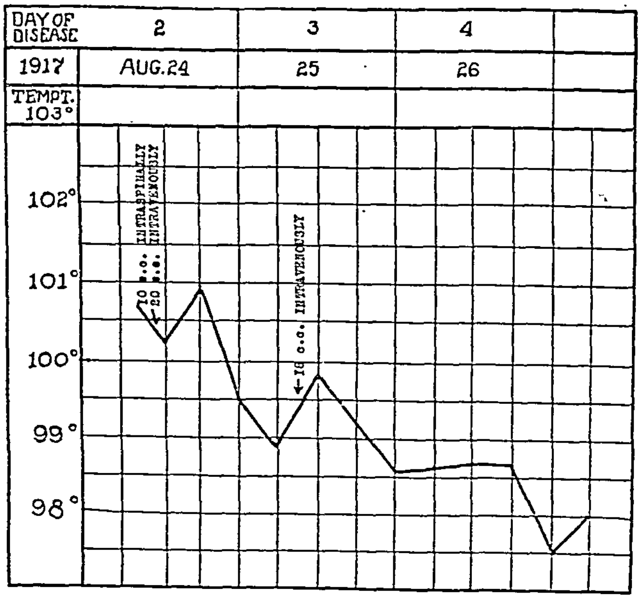

Chart 4 (Case 28).—Temperature curve of a patient admitted to the hospital with flaccid paralysis of both legs. Marked stupor and rigid neck. This patient recovered, with partial use of the legs.

This case is of interest for several reasons. It represents the typical form of Landry's paralysis with rapid ascending progression of the paralysis and ultimate involvement of the respiratory center and death. Not a few similar cases have occurred in this epidemic. The optimal time for serum treatment obviously was between July 26 and July 28. Seventy-two hours after the onset and at a time when all the extremities were paralyzed, the respiratory center involved, and the prognosis certain, 10 c.c. of serum were given intraspinally. The temperature dropped from 103 to 100, and accordingly a second dose of 10 c.c. serum was administered. Death occurred, July 31. This case serves to confirm the impression gained of the futility of any form of treatment after the respiratory center has become involved. Furthermore, we subsequently learned that the best results have been obtained in those patients receiving larger doses of serum.

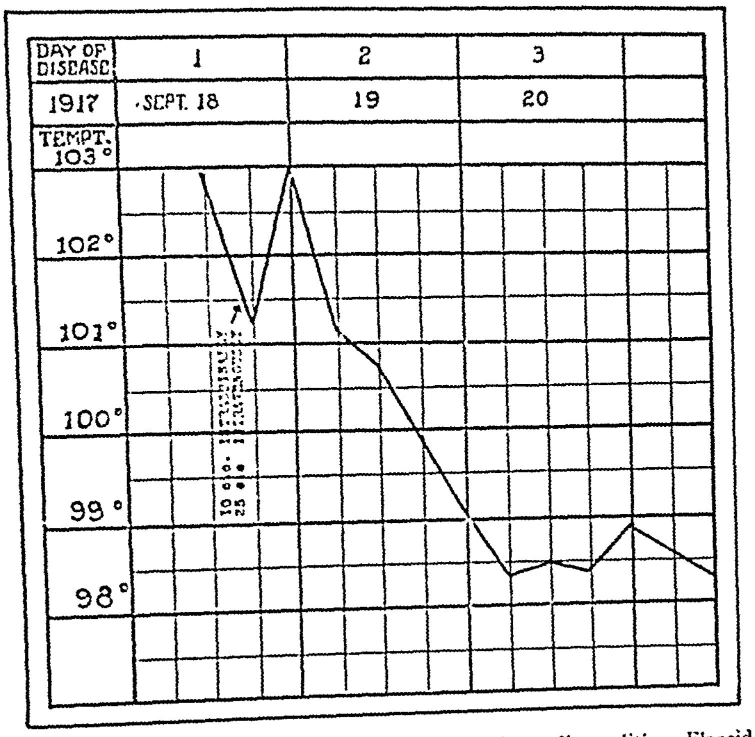

Chart 5.—Temperature curve of a patient with poliomyelitis. Flaccid paralysis of both legs with paresis of the right arm and shoulder. Duration of paralysis, seventy-two hours. The weakness of the arm disappeared rapidly following serum, and the paralysis did not progress. The legs remained flaccid.

Case 74.—Boy, aged 2 years, Sept. 9, 1917, had fever, headache and vomiting. September 10, there was weakness of both legs. September 12, he was admitted to the hospital. The temperature was 100. There was flaccid paralysis of the right leg. Weakness of the left leg was marked. The head fell backward when the child was raised by the shoulders, and the neck muscles were paretic. The cerebrospinal fluid was clear and contained 50 cells per cubic millimeter. The globulin test was + + +. September 12, 6 c.c. of serum were injected intraspinally, and 20 c.c. intravenously, and September 14, 10 c.c. intraspinally and 20 c.c. intravenously. September 15, the temperature was normal and has remained normal to date. The paresis of the neck muscles and right leg rapidly disappeared. The flaccid paralysis of the left leg still remains.

Serum therapy was instituted forty-nine hours after the onset of paralysis in this patient. A total of 50 c.c. of serum was injected, and the temperature dropped to normal within twenty-four hours. The paresis of the right leg never progressed, and the weakness of the neck muscles rapidly disappeared. This coincides with our observations that it is much easier to prevent paralysis altogether and to lessen the spread and severity than to effect its rapid retrogression.

Class 2. Paralysis Present

Case 95.—Boy, aged 5 years, Sept. 13, 1917, had fever, headache and vomiting. September 17, he had pain in the left shoulder and back, and was unable to use the left arm. September 17, he was admitted to the hospital. The temperature was 103. Pain was elicited on manipulation of the left shoulder. There was definite paresis of the left shoulder muscles. The cerebrospinal fluid was clear and under increased pressure; it contained 21 lymphocytes per cubic millimeter. Globulin was increased. September 17, 10 c.c. of serum were injected intraspinally and 25 c.c. intravenously. The temperature dropped to normal within thirty-six hours. There was no extension of the paralysis. On discharge from the hospital the child has regained complete muscular power in the left shoulder girdle and arm.

Case 4.—Onset in a boy, aged 9 months, occurred, July 27, 1917, with fever and vomiting. July 28, weakness of both legs was noted and inability to stand. July 29, on admission to the hospital, the temperature was 101. There were complete flaccid paralysis of the left lower extremity, and weakness and paresis of the right leg. The cerebrospinal fluid contained 33 cells per cubic millimeter. Globulin tests were positive. July 29, the patient received 10 c.c. of serum intraspinally. July 31, the temperature was 99.2; 5 c.c. of serum were injected intraspinally. August 2, the temperature was normal. No extension of the paralysis had occurred. August 4, 5 c.c. of serum were injected intraspinally and 10 c.c. intravenously. The paresis of the right leg cleared up. The left leg remained flaccid on the patient's discharge from the hospital.

Case 97.—Onset in a boy, aged 10 years, occurred, Sept. 15, 1917, with headache, fever and vomiting. September 18, there was weakness of both legs, and the patient could not stand up. September 19, on admission to the hospital, the child appeared acutely ill. There was paralysis of both legs, with loss of tendon reflexes. Both arms were paretic, and he could move only the fingers. The spinal fluid was clear and contained 109 cells per cubic millimeter with globulin + + +. September 18, 15 c.c. of serum were injected intraspinally and 20 c.c. intravenously. September 21, the temperature was normal and has remained normal to date. The paresis of the arms has rapidly disappeared, and the patient has good use of the arms and the hands. September 30, the

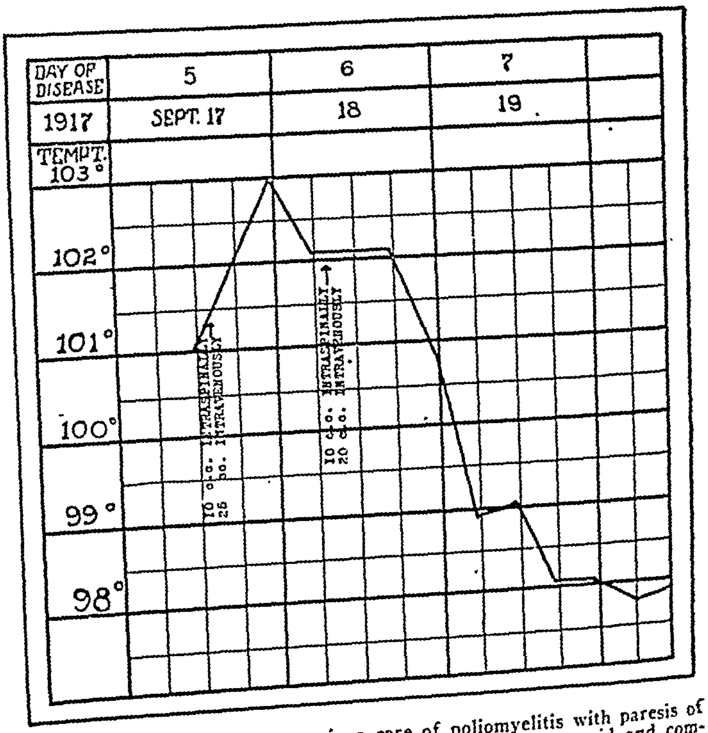

Chart 6.—Temperature curve in a case of poliomyelitis with paresis of the muscle groups of the left shoulder. Patient made a rapid and complete recovery following serum treatment.

legs have remained flaccid, and the Achilles and patellar reflexes are still absent.

CASE 6.—Girl, aged 11 months, Aug. 2, 1917, was admitted to the hospital with a history of the onset of paralysis seventy-two hours before. The temperature was 102. There was flaccid paralysis of both legs, with loss of reflexes. There was left sided facial paralysis. The neck was rigid and the spine sign positive. There was spasticity of both arms. August 3, 3 c.c. of serum were injected intraspinally and 10 c.c. intravenously. August 4, the temperature was 101.4. The condition remained unchanged. Three c.c. of serum were injected intraspinally and 10 c.c. intravenously. August 5, the temperature dropped to normal and has remained normal to date. The facial paralysis and rigidity of the neck rapidly disappeared. The legs are still flaccid.

CASE 65.—The onset of disease in a boy, aged 14 months, occurred Sept. 4, 1917, with fever and vomiting. September 9, paralysis of both legs developed. September 11, on admission to the hospital, the temperature was 100. There were flaccid paralysis of the legs and a paresis of the neck muscles. Six c.c. of serum were injected intraspinally and 25 c.c. intravenously. There was a critical drop in temperature to normal within twenty-four hours after the injection. The weakness of the neck muscles rapidly disappeared. The paralysis of the legs has remained unaltered.

CASE 118.—The onset in a girl, aged 1 year, occurred, Sept. 22, 1917, with vomiting and fever. She was admitted to the hospital, September 23, just twenty-four hours after the first symptoms. The temperature was 102. The child appeared acutely ill. There was marked left sided facial paralysis, with inability to close the left eye. The left corner of the mouth drooped completely. No paralysis of the extremities was detected. The spinal fluid contained 21 lymphocytes per cubic millimeter, with positive Noguchi, Nonne and Ross Jones tests. September 23, just twenty-four hours after the onset, 5 c.c. of serum were injected intraspinally and 15 c.c. intravenously. A critical drop of the temperature to normal occurred the following day. Paralysis has never appeared in the extremities. September 30, facial paralysis is disappearing, and the prognosis for complete recovery is excellent.

CASE 107.—Girl, aged 2½ years, Sept. 16, 1917, had fever and headache. September 20, weakness of the left arm appeared. September 21 she was admitted to the ward. The temperature was 101. The child appeared acutely ill. She was stuporous. The neck muscles were paretic. There was weakness of the left shoulder and arm. The deltoid muscle was paretic, with loss of reflexes in the left arm and shoulder. September 21, twenty-six hours after the onset of weakness of the shoulder and neck muscles, 10 c.c. of serum were injected intraspinally and 25 c.c. intravenously. September 22, the condition had improved and the stupor was gone. Ten c.c. of serum were injected intraspinally and 20 c.c. intravenously. September 25, the temperature reached normal, and there had been a rapid general improvement. The paresis never progressed. The child can move the left arm in all directions, and the prognosis appears excellent for complete recovery.

The foregoing case histories are included to illustrate the definite value of serum treatment in preventing the spread of the paralysis. All of these patients were treated at the optimal time, from twenty-four to forty-eight hours after onset. It will be noted that while the paretic muscles and weakness of the extremities rapidly disappeared following serum therapy, flaccid paralyses remained unaltered.

COMMENT

We have treated a series of 159 cases of poliomyelitis with immune serum prepared in the horse by repeated intravenous injections of the coccus isolated chiefly from human poliomyelitic sources. Prior to its use in man, we have proved that this serum, prepared in the horse in the manner outlined above, possesses both protective and curative properties in experimental poliomyelitis in monkeys. We proceed now to the estimation of the value of the serum in human poliomyelitis. It is obvious that the value of serum must be based both on the clinical study and impressions gained in the treatment of individual cases, and on statistical evidence acquired after treatment of a large series of cases properly controlled.

Of the group of fourteen cases of undoubted instances of poliomyelitis in which no paralysis could be detected at the time serum treatment was instituted, thirteen patients recovered completely and one died. None of these patients developed paralysis, subsequent to serum treatment. These facts serve to substantiate the impression gained from the treatment of the entire series of cases, that it is much easier to prevent paralysis altogether and definitely to arrest the extension and lessen the severity of the paralysis than to bring about its rapid disappearance. It should be mentioned in this connection, however, that we have repeatedly observed definite weakness or paresis of extremities rapidly disappear following serum therapy. Furthermore, of the entire 159 cases treated in all stages of paralysis, in only three late cases has the paralysis extended to the respiratory center with a fatal result. This is significant when we recall the unusually high mortality of the present epidemic with the relatively large number of fatal respiratory paralyses among untreated patients.

Regarding the mortality rate, we have thus far treated a total number of 159 patients with nineteen deaths, a mortality of 11.3 per cent. Mention should be made of the fact that of these nineteen fatal cases, seven patients were admitted to the hospital with advanced respiratory paralysis, and all died within periods varying from seven to seventy-two hours after admission. These patients have been included in estimating the total mortality, obviously an unfair test for estimating the therapeutic efficiency of the serum.

From statistics kindly furnished by the Health Department of the city of Chicago, a total of 301 cases were reported with ninety-seven deaths, a mortality of 32 per cent. for the period of July 20 to Oct. 1, 1917. During this same period of time we have treated a series of 152 patients, excluding seven respiratory paralyses on admission, with twelve deaths, giving a mortality rate of 7.5 per cent.

In by far the majority of patients receiving serum, the fever, at times high, has fallen rapidly to normal within periods varying from twelve to twenty-four hours. Coincident with this critical drop of the temperature there usually occurs a slowing of the pulse rate and other clinical evidence of rapid general improvement.

Finally, we wish to consider briefly the extremely important problem of the dosage and mode of administration of the serum. A careful analysis of the case histories suffices to demonstrate the harmlessness of the serum when slowly injected both intraspinally and intravenously. The serum has always been tested for sterility after passage through a Berkefeld filter, and has been used without a preservative. It must be free from corpuscles and hemoglobin.

As in other acute infectious diseases, recovery from poliomyelitis must depend on the process of self-immunization. Accordingly, the simultaneous intraspinal and intravenous injections of immune serum afford the most rapid way of flooding the central nervous system with specific antibodies to neutralize the virus of the disease. We have attempted to treat all cases as early as possible with relatively large doses of serum. Obviously the amount of serum that can be safely given to a child intraspinally is small. Accordingly, we have regularly injected small doses of from 5 to 10 c.c. of serum very slowly by the gravity method after the previous withdrawal of an equal or greater amount of spinal fluid. At the same time intravenous doses of from 10 to 30 c.c. of serum are given according to the age of the patient. In many patients we have repeated the intravenous injections at twelve to twenty-four hour intervals, using the temperature as a guide to dosage, with beneficial results. The majority of patients have received total amounts of serum varying from 40 to 75 c.c., depending on the age and severity of the case. In a few critical cases we have injected a total amount of 150 c.c. within seventy-two hours, with beneficial results.

SUMMARY

1. Of 159 patients receiving serum in all stages of the disease, nineteen died, a mortality of 11.9 per cent. Among 100 cases occurring during the same period of time, in which the patients did not receive serum, thirty-eight patients died, a mortality of 38 per cent.

2. We have treated 152 patients in all stages of infantile paralysis, excluding seven cases presenting respiratory paralysis on admission, with eleven deaths —a mortality rate of 7.2 per cent. During this same period of time a total of 301 cases were reported to the Health Department with ninety-seven deaths—a mortality of 32 per cent.

3. This series of treated cases suffices to demonstrate the harmlessness of serum treatment when the serum is free from hemoglobin, sterile to repeated cultures, and the injections are slowly made and all known rules of precaution are observed.

4. The serum appears to possess the power of definitely preventing the onset of paralysis when administered early in the disease. In ten undoubted instances of poliomyelitis in which no paralysis was detected at the time serum was administered, prevention of paralysis and complete recovery resulted in 100 per cent.

5. The action of the serum is more definite in arresting the extension of paralysis and diminishing the severity than in effecting its disappearance.

6. As in other acute infectious diseases, the earlier the serum is administered, the more striking are the results obtained.

7. Serum should be injected intraspinally in small doses and at the same time intravenously in larger amounts. The temperature has been employed as a guide to the dosage.

8. The injection of serum is followed by a critical fall in the patient's temperature. Coincident with this there occurs a slowing of the pulse rate, and usually other definite clinical evidence of general improvement.

9. In doubtful early cases the decision to use serum should rest on the bacteriologic, chemical and microscopic examination of the cerebrospinal fluid.

Negroes Show Lower Suicide Rates than White Persons. —The death rate from suicide among negro males is a little over one half as high as among white males, according to statistics of the Metropolitan Life Insurance Co. In 1916, the rate was 8.2 per hundred thousand insured. Negro females show the very lowest rates of any of the groups studied. The rate was 3.4 per hundred thousand in 1916, the total number of suicides being only twenty-two among over 650,000 insured colored women.

Military Medicine and Surgery

MILITARY SKETCHING AND MAP READING

WILLIAM W. RENO, A.M., M.D.
Lieutenant-Colonel, Medical Corps, U. S. Army; Instructor, Medical Officers' Training Camp
FORT RILEY, KAN.

The ability to read maps is an absolutely essential qualification of a medical officer. Instructions conveyed to him in the field often contain references to maps. If he is unable to understand these references his efficiency is greatly impaired. Then, too, the question of shelter and cover from fire at distant points at which it might be desirable to establish sanitary formations can often be determined by reference to maps.

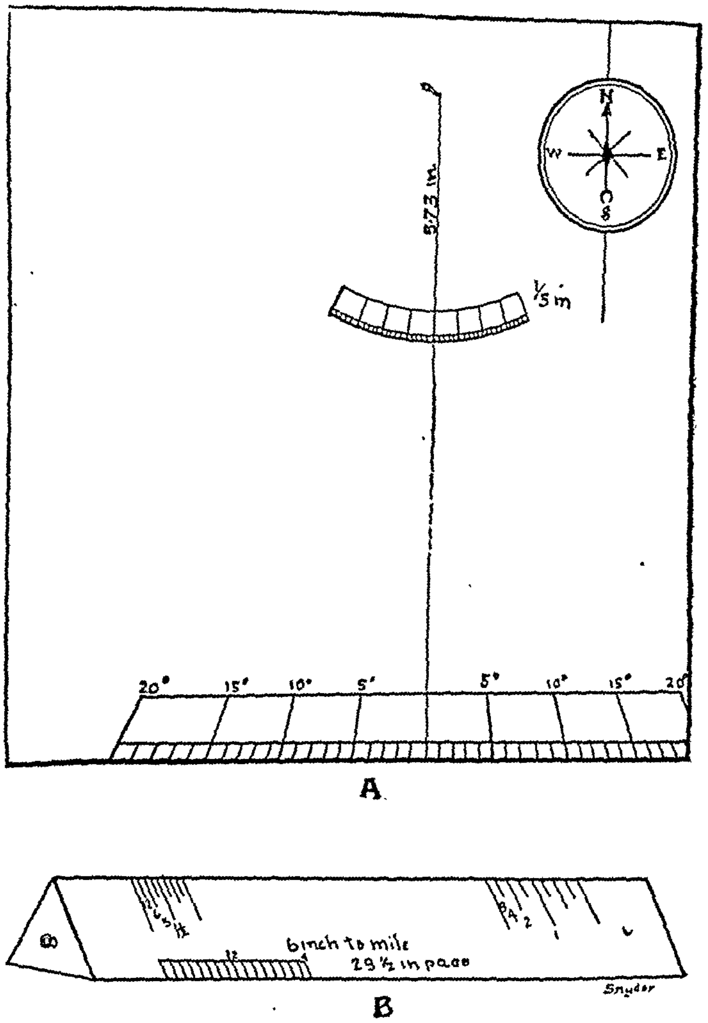

Fig. 1.—(*A*) This is merely a piece of a 1 by 12 inch board with angles of slope marked on it. With a plumb bob and line attached as shown, and sighting at an object over the top of the board the angle of elevation of the object is registered by the plumb line. Knowing this angle and the distance to the object, the elevation of the object can be readily ascertained from the degree scale on the alidade. (*B*) The alidade is a triangular ruler used for sighting at objects and drawing lines (rays) on the map. It has on its faces one's pace scale; also a degree scale, an inch scale and a hundred yard scale.

As the shortest road to map reading is through map making, the essentials of map making will be outlined. Ordinarily in two afternoons the general principles of map making can be mastered. In working out the principles of map making the essentials of map reading will be absorbed unconsciously.

ARTICLES NEEDED FOR MAP MAKING

Compass, alidade, slope board, tripod, paper, four thumb tacks, pencil with eraser, a pace tallier (convenient but not essential), a list of pace scales for paces from 28 to 36 inches (convenient but not essential) are needed.[1]

PROCEDURE

1. *Normal Step or Pace.*—This is determined in the following manner and marked on the alidade: One walks four times over a measured one-half mile course and counts the number of one's steps each time. These are added together and divided by four to get one's average number of steps or paces per one-half mile. There are 31,680 inches in one-half mile. This number is divided by the foregoing average. This gives the length of one's pace in inches. All sketches made should be on the scale of 6 inches equal 1 mile. One's pace on the list of scales furnished is located and a corresponding scale on the blank side of the alidade is marked. This scale of one's paces is necessary in order to step off distances and place them on one's sketch.

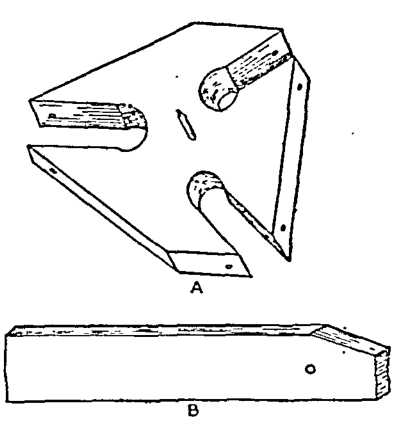

Fig. 2.—The tripod is easily made. A piece of board 2 by 4 inches, or preferably 2 by 6 and 6 inches long, is selected and three slots are made for the legs. Four strips of board about 1 by 1 by 4 inches serve as legs. With nails these are fastened into the slots. A nail is driven through the slotted piece from the bottom and projects through the top one-half inch. A nail hole three-fourths inch deep is made in the bottom center of the map board. A nail is driven through this hole and the tripod and the board are ready for setting up. *A*, head piece; *B*, leg.

2. *Slope Board and Tripod.*—A piece of 1 by 12 inch lumber about 1 foot long is taken for a slope board (Fig. 1). For a tripod three slender strips of wood about 4 feet long are chosen for the legs and are attached to a block of wood for the head piece, the legs being placed into slots and nails driven through them in order to hinge them. Through the center of the head piece, from below, a nail is driven and allowed to project through the upper side about one-half inch. A corresponding hole is made in the center of the bottom of one's map or slope board. This gives a pivot for one's map board on the tripod (Fig. 2).

3. *Degree Scale on Slope Board.*—One edge should be perfectly straight. A line perpendicular to this edge is drawn on the face of the board. On this line is drawn an arc of a circle with a 5.73 inch radius. The arc should extend about 3 inches on each side of the perpendicular, and the center of the circle should be on the perpendicular about one-fourth inch from the straight edge mentioned. Dots should be marked on this arc one-tenth of an inch apart, beginning at the perpendicular and going both ways. A pin is driven into the center of the circle. A thread 15 or 16 inches long should be tied to the pin. The thread is drawn taut, covering the perpendicular. It is then moved either way, still taut, until it covers a one-tenth inch dot. Then a dot is placed where the thread crosses the edge, opposite the straight edge. This should be done for fifteen or twenty dots on each side of the perpendicular. At each dot so made a line is drawn one-fourth inch long toward the center of the circle, except that at every fifth dot a line one-half inch long should be made. The long lines should be numbered 5, 10, 15, etc., on each side from the perpendicular as zero. This board is now a slope board for marking the degree of slope of hills, valleys and other objects (Fig. 1 A). When the alidade or a piece of lead is tied to the thread mentioned, acting as a pendulum, and a sight is taken along the straight edge of the board, the thread marks, on the edge opposite, the degree of slope of the hill, or other object sighted. The thread is caught at the proper point by pressing it against the board with the finger. If the elevation on which one stands is known or assumed, and the distance to the top of the hill is known, the elevation of the hill is readily calculated from degree scales on the alidade. The distance to the top of the hill can be readily ascertained by pacing, or by intersection or resection, as will be explained later.

4. *The Compass and Orientation.*—The compass points to the magnetic north, which is in Greenland. The variation from true north is called "declination of the needle." It can be readily ascertained by finding the true north, or from official maps. It is negligible in sketches. In order to make accurate sketches, whenever the map board is on its tripod, the board must be oriented, that is, it must be set in such a manner that directions on the map and the ground coincide. This is easily done by placing a compass on the board and getting its needle in line with a line previously drawn on the board. For convenience it is well to countersink a hole, compass-shaped, at one corner of the board and to draw an arrow passing through the needle pivot. The point of the needle must be kept on this line, and its north point must always point toward the arrow point. When this is done, the map and the ground directions always coincide.

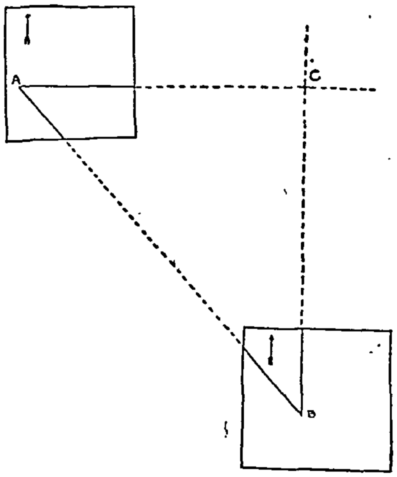

Fig. 3.—Location of a critical point by intersection. It is desired to locate point C on the ground at its proper place on the map. The map board is set up at A. The board is oriented. A ray is shot at B and C. One paces to B. The distance as laid off A to B on one's map. The board is again oriented. A ray is shot at C. The point at which the rays A-C and B-C cross is the proper place for C on the map.

5. *Critical Points.*—These are prominent points on the ground selected as points for exact location on the map. These points are located by (a) pacing, (b) intersection, (c) resection.

(*a*) By Pacing: A starting point is assumed and marked with a sharp pencil point on one's map (board oriented) with the map paper, and the country to be mapped, before one. From this point (A) a light line is drawn on the paper (called a ray) directly at the object (B), by sighting across the top of the alidade and pivoting the alidade on the map point by means of a sharp pencil. The alidade should always be kept at the left of the pencil. Before the ray is drawn, the needle should be again examined to be sure that orientation is exact. If it is not exact, it should be made so, and a new sight taken across the alidade. A ray should never be drawn on the map without a final look at the orientation in order to insure accuracy. When this ray is drawn (a very light line, so it may be erased if need be) one picks up the board and tripod and paces to the critical point, counting the steps. This distance is laid off on the ray by using the pace scale on the alidade. All superfluous rays are now erased.

---

[1] Alidade and list of pace scales can be obtained from the book department, Army Service Schools, Fort Leavenworth, Kan., price 20 cents.

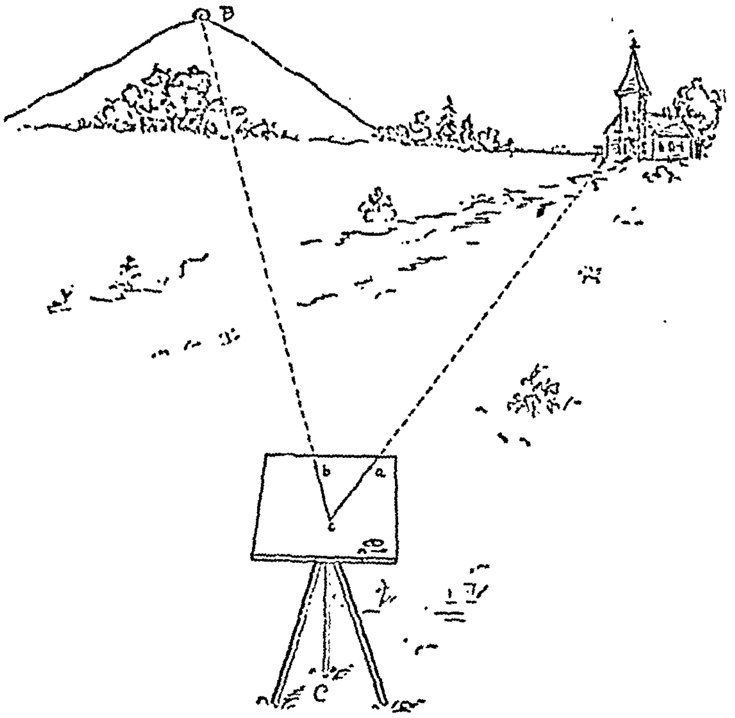

Fig. 4.—Location of a critical point by resection. This method locates on the map the point at which one is standing on the ground. Two critical points visible on the ground must already be located on the map, for example, the house A and the church B. The board is oriented. One pivots the alidade on *a* and sights at A, and standing at the rear of the map board a line is drawn along the alidade from *a* toward the body. This is repeated at *b*. The point at which *a-c* and *b-c* cross locates on the map the point at which one stands, or point C.

(*b*) By Intersection: We will assume that point C is off to one side of A and B, and that its location is desired. While at A a ray is shot at C (board oriented). Also when at B, a ray is shot at C (board oriented). Point C is the point at which these two rays intersect. A sharp point is made there, and marked C. These two rays (and all "dead" rays, that is, rays no longer needed) are erased, in order not to clutter up the map with useless lines (Fig. 3).

(*c*) By Resection: Often it is desirable to locate on the map the point at which one is standing on the ground. We will assume that one is on the ground at point C. The board is oriented and the alidade is pivoted on point A on the map by sighting at point A on the ground. A line is drawn from point A on the map, toward one's body, likewise another line is drawn from point B on the map. The point at which the two lines cross is point C. This point and all critical points are marked when found with a sharp pencil point (Fig. 4).

6. *Determination of Elevations.*—If it is unknown, an elevation is assumed for one's starting point. For example, point A may be assumed to have an elevation of 500 feet. It is desired to get the elevation of point H. Point H has already been located on the map by one of the three methods mentioned—pacing, intersection or resection. While at A the angle of elevation of H is obtained. We will assume it is 8 degrees. The 8 degree scale on the alidade is then found. Every time the distance for 8 degrees on the scale goes into the distance between points A and H on the map is a rise of 10 feet on a 6 inch to the mile map. We will assume the map distance from A to H is ten 8 degree distances. Then point H is 80 feet higher than point A and the elevation of H is 580 feet. Of course, if H is lower than A, it is 80 feet lower, and its elevation is 420 feet.

7. *Contours.*—These are lines cut on the earth's surface by imaginary horizontal planes at equal intervals from each other. They are needed on flat maps in order to show the elevation and shape of hills and valleys. All points on a contour line are of equal elevation. When contours are equally spaced the slope is uniform. Contours close to each other indicate a steep hill; far apart, gentle slope. Contour lines pass obtusely around slopes and acutely up streams or dry water courses. When the elevation of a critical point from another point is to be ascertained, the slope of the land should be noted, and for every intermediate contour indicated a dot should be placed. This should be done regularly. When the location and elevations of all critical points are determined, one should dot between them where contours would pass; all dots of equal elevation should be connected, and one's map is contoured. It should then give an accurate reproduction of the land mapped.

8. *Scales.*—In United States Army field sketches the normal system of scales is used. That means that the distance between contours called V.I. (vertical interval) varies regularly according to the scale of the map. If 1 inch on the map paper equals 1 mile on the ground map, the V.I. is 60 feet. If 3 inches on the map equal 1 mile on the ground the vertical interval is 20 feet; for a 6 inch map the V.I. is 10 feet, etc. Sixty divided by the scale of the map gives the vertical interval. This normal system was adopted in order to use the same degree scale for various sized maps. The distances on the degree scales on the alidade vary inversely with the angle. Those distances are called map distances between contours or M.D.'s. The M.D. for 1 degree is 0.65 inch. All other M.D.'s can be derived from this if no alidade is at hand. A pace scale is necessary in order to have a ready means of measurement of ground distances, readily convertible from the map into distances. Animal scale is the pace scale applied to a riding horse. The time required for the animal to go fixed distances at a walk or trot is, however, used as the standard unit instead of the length of its pace.

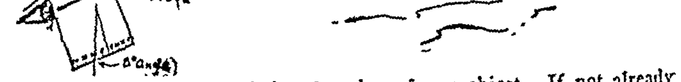

Fig. 5.—Determination of the elevation of any object. If not already known, an elevation for the point A where one stands is assumed. With the map board one sights at H, the point whose elevation is desired. The distance to H has already been determined by pacing, intersection or resection. We will assume the angle of sight is 8 degrees. From the alidade the elevation of H is then easily determined.

9. *Base Line.*—Any paced distance is a base line. A line is absolutely necessary in starting a map, before points can be located by intersection. Two critical points visible at the point to be resected and correctly located on the map are always necessary before a point can be located by resection. In intersection and resection the angle between the rays at the critical

point to be located must never be less than 30 degrees or greater than 100 degrees, as otherwise the rays are so nearly parallel that great error is possible.

10. *Conventional Signs.*—These are certain abbreviations or marks used in mapping to avoid writing out words—a map shorthand, as it were. They are very simple and are usually self explanatory.

11. *Types of Sketches.*—There are four types of sketches—road, position, outpost and place sketches. (*a*) The road sketch is a sketch of a road and an area extending about 400 yards on each side of it. As a rule all details needed can be obtained from high places in the road. It may be necessary at times to go to high places near the road. Bridges, fords, ferries, houses, woods, cultivated fields, nature of crops and soil, villages, high hills, valleys, streams, and other points of importance are noted on the sketch. These objects should be noted in all sketches when possible. (*b*) The position sketch is an area sketch of such a nature that the sketcher can visit, if desired, any point in the area to be sketched. (*c*) In the outpost sketch the observer can visit only the land in the rear of his outpost. (*d*) The place sketch is made from a single point of observation, as a tree or a high hill. In this sketch the observer must estimate distances. Sizes of known objects assist greatly in estimating distances. Distances between telegraph and telephone poles are also of great value.

12. *Comparison of Work.*—We will assume that ten men are mapping the same area, all having a different space but mapping on a 6 inch scale. When the maps are completed all similar distances should measure exactly the same on every map. Contours should look approximately alike.

13. *Sketching without Special Equipment.*—Articles needed: a watch, a piece of paper, a pencil and a flat surface for holding the paper. One's pace is determined and placed on a piece of paper on a 6 inch scale. If one has not this scale at hand, one should be devised. Means are readily at hand everywhere. Each time one starts to work on one's map, the map paper should be oriented by means of a watch (accurately recording sun-time, of course) as follows: The hour hand is pointed at the sun. Midway between the hour hand and 12 o'clock is the north and south line. The position of the sun will tell you which end is north. To get the hour hand pointing directly at the sun a match, or other straight slender object, is held so that its shadow falls across the face of the watch. The hour hand, pointing at the sun should lie directly in this shadow. Now one proceeds to make one's map by pacing, intersection or resection. A slope board is made on one's flat surface and a tripod and alidade are improvised if elevations are desired. Degrees of slope are readily placed on the alidade by remembering that 0.65 inch is the M.D. for a 1 degree slope; half that is the M.D. for a 2 degree slope, etc.

14. *Boundary.*—The boundary of any map sketched is made by connecting outermost critical points by straight lines.

15. *Data.*—When a sketch is completed the following data should be placed on it:

1. Name, rank and organization of sketcher.
2. Date of sketch.
3. Location of sketch.
4. Map scale and arrow pointing to magnetic north.
5. Elevation in figures of critical points if elevations are taken. Also contours.
6. A careful outline of water courses and dry runs.

MAP READING

As the principles of map making can be learned in a few hours it is always advisable to learn map making before map reading. When the anatomy of the map is mastered, map reading is simple. Hill slopes should be thought of in degrees so that by looking at the map one can say: That is an 8 degree hill, a 5 degree hill or whatever its height may be. This is of great value in determining whether the hill, ravine, or whatever topographic feature it may be gives protection from rifle or artillery fire. Slopes of the fall of bullets and shells should be learned in order to complete this valuable information.

VENEREAL DISEASE AND THE NEW ARMY

WILLIAM LYSTER, M.D.
Lieutenant-Colonel, Medical Corps, U. S. Army
LONDON, ENGLAND

What will be the history of these diseases in the new Army now being raised? This question is of utmost importance to the country at large for these reasons:

1. These diseases constitute the greatest factor producing nonefficiency in armies in training.

2. The increase of damage to the national health through the spread of these diseases.

3. The unprecedented opportunity afforded by the concentration of such a large proportion of the male population for public education on these diseases.

War always means the interruption and dislocation of existing conditions. The greater and larger the war and the larger the proportion of the population involved, the more extensive is the effect on the national life.

The history of these diseases in the armies, and more particularly in our own, will give us a safe indication of what may be reasonably expected under the same conditions. But today we are in possession of knowledge and agencies that were wanting until recently. What these are and what their effect is will be mentioned shortly.

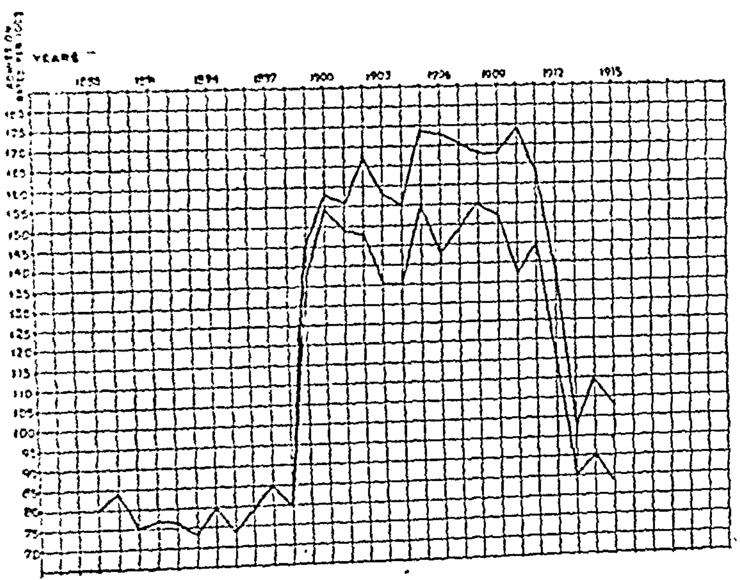
The history of venereal disease in the American Army can be most rapidly grasped by studying the annual admission rates for these diseases as shown in charts or tables. I have drawn a curve as made by these annual rates from 1888 to 1915, inclusive. The rates are those to be found in the annual report of the Surgeon-General to the Secretary of War.

The chart divides itself rather naturally into three parts representing stages radically different in character. The rates for these distinct stages differ markedly.

The first stage, from 1888 to 1898, covers the decade in which the U. S. Army was strictly continental. It was scattered in small commands mostly west of the Mississippi and in the southwestern states. The rank and file were, like the officers, professional soldiers and the age and length of service made these men "old soldiers." For the bulk of the troops the contact with cities and towns was casual and not daily. No regular physical inspection with special reference to venereal disease was frequently made, as is now done fortnightly. Ready and exact means of diagnosing syphilis did not exist. The Wassermann reaction and the cause of syphilis were not known. Naturally, as in civil practice, many cases of this disease appeared under other names, as it was not recognized, for instance, rheumatism and heart disease of some kind. Any one who reads the oration delivered by Sir William Osler before the London Medical Society, published in the *Lancet,* or having heard it delivered, as I had the privilege of doing, will understand the truth of this statement.

During this decade, there was no systematic centrally controlled propaganda to reduce venereal disease. The very attitude of the profession was different from what it is today. A deprecatory, sub rosa, hush atmosphere surrounded the subject. One looks in vain for a discussion of venereal diseases in the lay press. Mention of them was indirect even in the most bold quack advertisements. The word "syphilis" is not to be found in print outside of medical publications.

With these conditions characteristic of this decade in the Army, namely, isolation, no regular inspection for veneral disease, no systematic campaign to reduce the amount of venereal disease, and, in addition, the indefiniteness in diagnosis inseparable from the methods of that time, the average admission rate for the period may be taken as seventy-eight per thousand.



Curves showing the incidence of venereal diseases in the United States Army from 1888 to 1915. The rapid decrease in venereal diseases for the years from 1910 to 1913, following systematic measures instituted by the government for their control, should be noted.

The lower line shows rates for enlisted force in the United States. The upper line shows rates for all enlisted force both in United States and abroad.

1888-98.—During this decade the Army was stationed throughout the U. S., principally at small points. No compulsory physical inspection; no systematic propaganda to reduce venereal disease. The rates represent practically those patients unable to do duty. Cases not treated or in those doing duty were usually not recorded.

1898.—Spanish War Militia called into service.

1898-99.—Great change in Army. Marked expansion. Old soldiers disappear. Volunteers come in. Young recruits sent to Cuba, Porto Rico, Philippines.

1899-01.—Philippine Insurrection Troops in Cuba, Porto Rico, China.

1901-09.—High rates prevail in U. S. and abroad.

1909-11.—Principles of preventive medicine applied. Prophylaxis urged.

1911.—Syphilis increases. Wassermann test used in diagnosis.

1912.—Systematic measures. Fortnightly physical inspections and prophylaxis enforced by G. O. May 31. Pay stopped G. O. 31.

1914-15.—Concentration on Mexican Border.

The second stage, from 1898 *to* 1908, embraces the decade in which there were radical changes in army life introduced by the Spanish War. Conditions of war necessitated a sudden increase in the Army. Naturally new and untrained material was brought in. A dropping out of the "old" soldiers took place. The tropics were penetrated. The isolation of the old-Army in the West was a thing of the past. There was contact with cities, either from camps near them, or by waiting in them for transportation overseas, as at San Francisco and Manila, and finally there was association in the tropics with people on a lower social plane.

The most important factors are the breaking away from the home ties and control of a large number of young men, and their projection into surroundings to which they were unaccustomed.

This stage shows a double line. The outer or higher indicates the rates for the Army both in the United States and in the new tropical dependencies, Porto Rico, Cuba and the Philippine Islands. The inner or lower line shows the rates for the U. S. Army in the United States. This line affords a comparison with the line to the left for 1888-1898. The conditions encountered in the tropics make the difference between the outer and inner lines. Lack of regular physical examinations and systematic propaganda against venereal disease characterize this period the same as the first. But the rates, which had steadily mounted until they were almost double the recorded rates of the first decade, were so preposterous that attention was concentrated on them, owing to the nonefficiency produced by these diseases, which, during several years, was about equal to the five diseases next in order of frequency.

Individual spasmodic effort to remedy conditions began. The post surgeons undertook various measures to restrict these diseases. Their efforts were studied by the Surgeon-General's Office, and gradually a systematic campaign was developed, the good results of which appear in the third stage. This was largely assisted, and made possible, in fact, by the discoveries of science—which were promptly utilized.

From 1909 to 1911, the principle of preventive medicine began to be applied extensively. Metchnikoff's experiments relative to the prophylaxis of syphilis subsequent to Schaudinn's discovery had been published. They bore fruit rapidly in the Army, which was affected with such a high venereal rate, and various experimenters in the Army, prominent among them Colonel Mans and Colonel Howard, obtained notable results in lowering the veneral rate by devising satisfactory prophylactic measures.

In the early part of the third stage, the introduction of the Wassermann test and vaccine in the treatment of gonorrheal arthritis is an outstanding feature. The Wassermann test tended to give an increase in the ratios owing to the more accurate means of diagnosis afforded. This system of recording cases was still more marked in 1912, when fortnightly physical inspection was ordered. When carefully done, this permits the discovery of practically all cases of venereal disease except some cases of syphilis. The latter cases, if the patients ever go to the hospital, are now pretty surely found by the use of the Wassermann test, which is ordinarily employed in all obscure or doubtful cases.

Could these methods, fortnightly examinations and the Wassermann test, have been applied in the first stage, from 1888 to 1898, the rate would have been much higher, possibly as much as 110 or more admissions per thousand; for the rates in that period indicate practically only those men who were unable to perform duty and only for that reason appeared on the sick report. At the present time every case appears in the rates whether the man is performing duty or not.

The results of spasmodic and uncentralized efforts to reduce venereal disease appeared in 1911. The effect of centralized and official efforts were apparent in 1912, when the rate was shown to have fallen for the entire Army nearly forty points in two years. Inspection, prophylaxis, and loss of pay for disease not in line of duty are the prominent features. Men and officers who wilfully become incapacitated through ill health are subjected to loss of pay. The wise congressional action which permitted this step certainly should be retained. Its effect has been most powerful and far-reaching and tends to restrain the soldier from dissipation. As long as he cannot perform his duty, he certainly is not entitled to pay when he has wilfully disregarded orders and failed to take advantage of protective measures that would save him from ill health and the goverment from the loss of his services.

The line on this chart for the years from 1910 to 1913 is an outward and visible sign of some of the most creditable work ever accomplished by the Medical Department of the Army. It is also an example of the practical value of applied science. That this improvement was naturally assisted by the cessation of campaigns of any size in the tropics is true, just as, conversely, the concentration of the Army in the United States on the southern border and the dispatch of a part of it to Vera Cruz gave a higher rate in 1914. This, however, was probably aided by one of those reactions so frequently seen in all propagandas.

Now as to our new Army and the future: Higher rates will probably prevail for some time, but hope is backed by knowledge that we have the means, if we can apply them, of controlling this great producer of nonefficiency in armies. The education of the new medical officers is the first condition to success, the education of the line officers as to the supreme importance of the antivenereal campaign is the second, and the education of the enlisted men as to the necessity of prophylaxis after exposure is the third.

This is a practical question and no longer a theory that confronts the new Army. Its efficiency, its very numbers, are dependent on its health. The greatest enemy to its health is venereal disease. What will the answer be to the challenge that it is to meet within the next few months?

A continuation of the orders and methods successful in the Army from 1908 to date will make a successful answer to that challenge of disease. But no misleading and unpractical fanatics must be permitted to have a hand in this question of national efficiency any more than they shall be permitted to dictate as to the manner of making our gunpowder.

The gonococci have probably quite as ancient and respectable a lineage in biology as the pneumococci. The same relentless scientific measures that are used in the one case must be applied in the other, and no false sentiment must be allowed to interfere in the efficiency of their application. Prophylaxis has shown its great and proved value. As long as the instinct of procreation is as omnipresent and as powerful in nature as it is, it must enter into our problem.

Let those who regard veneral disease as a divine punishment recall that smallpox and other diseases have been at various times, and are even today by some regarded as acts of God. If fanatics must interfere in this beneficial work of reducing venereal disease, let them concentrate on an effort to remove the sexual appetite rather than insist on spreading venereal disease, even to the innocent, by abandoning one of the most useful agents in preventing it.

The responsibility devolves on the new medical officers to begin this necessary and beneficial work by thoroughly informing themselves, and then they must carry out the existing orders looking to the prevention of these diseases. All this must begin at home, and must become ingrained in the Army before it can maintain its health in the lands in which it is to justify its existence.

Adastral House, Victoria Embankment, E. C. 4.

THE VENEREAL DISEASES

COMPLICATIONS OF GONORRHEA

FOLLICULITIS

(Continued from page 1171)

NOTE.—This is the fifth article of the series on the management of venereal diseases with special reference to military practice. The first article on "The Diagnosis and Treatment of Syphilis" appeared, Sept. 15, 1917, page 907; the second, on "Chancroid," September 22, page 1004; the third, on "Balanitis Gangrenosa," September 29, page 1080; the fourth, "The Treatment of Gonorrhea," October 6, page 1168. The final article, including a program for the control of the venereal diseases and instructions to those having syphilis or gonorrhea, will appear next week. The articles have been prepared under the direction of the Surgeon-General by the Advisory Committee on Venereal Diseases, Dr. William Allen Pusey, Chicago, chairman; Dr. Francis R. Hagner, Washington, D. C.; Dr. Grover W. Wende, Buffalo; Dr. Sigmund Pollitzer, New York, and Dr. Henry H. Morton, Brooklyn, with Lieut.-Col. F. F. Russell in charge of infectious diseases. The series is published with the permission of the Surgeon-General. The articles are now being prepared in the form of a pocket manual, with flexible cloth cover. The book will be available shortly, price 25 cents.—Ed.

Suppuration of one of the urethral follicles with abscess formation occasionally occurs in gonorrhea. If it does not open into the urethra by the time fluctuation occurs, it should be incised. It is important to incise from within the urethra through a urethroscope if the abscess is connected with the urethra. Otherwise a urinary fistula may result.

COWPERITIS

This condition should be treated by incision from without.

GLANDULAR URETHRITIS

Many intractable cases of gonorrhea lasting for years in spite of constant treatment are caused by a chronic inflammation of Morgagni's crypts. Such cases show few symptoms. There may be merely a morning drop of moisture at the meatus. But they are characterized by exacerbations of the discharge after slight provocation, with a free discharge of pus containing gonococci, which leads the patient to believe that he has acquired a fresh infection. Urethroscopic examination shows the mouths of a few of the crypts to be open and pouting, with red and slightly elevated edges. In other cases the mouths of the crypts are occluded by a growth of epithelium. When the crypts are affected the gonococci may remain in them for years and the case remains infectious.

These cases should be treated by dilatations with a full sized sound followed by irrigations. When the mouths of the glands are occluded by the growth of epithelium, dilatation of the urethra opens them and forces out the purulent secretion. The irrigating fluid enters the cavities and acts on the chronic inflammatory processes within the glands. In that form of inflammation in which the mouths of the glands are held open and the entire crypt is stiffened and inelastic from the periglandular infiltration, dilatations cause the absorption of the infiltrate around the glands and promote a return to normal conditions.

When after sufficient treatment by dilatations and irrigations, it is found by urethroscopic examinations that a few glands still remain chronically inflamed and suppurating—conditions which supply foci of infection—these should be destroyed. This can be accomplished by bringing them into view with the urethroscope, and introducing a galvanocaustic needle. The cauterization must be very superficial and rapid; otherwise there will be danger of stricture formation. Three or four crypts may be destroyed at a sitting. It is possible by destroying the glands harboring the gonococci to cure in this way a chronic gonorrhea of years' standing which has resisted all the usual forms of treatment.

CHORDEE

The patient subject to chordee should empty his bladder just before going to bed; should sleep in a cool place, lightly covered; and, to avoid sleeping on his back, should tie a towel around his waist with a knot at the back. Before going to bed the penis should be given a prolonged immersion in hot water. When the patient wakes with chordee, he should get out of bed and immerse penis and testicles in cold or hot water, and before going back to bed should empty the bladder. He should be warned of the danger of "breaking" a chordee. In severe cases sedatives are necessary, potassium bromid, 2.0 gm., or camphor monobromate 0.3, gm., in the afternoon and before going to bed, are useful; in extreme cases a morphin suppository may be necessary.

EPIDIDYMITIS

Immediately on the development of epididymitis all injections or instrumentation of the urethra must be stopped, the patient be confined to bed and put on a light diet. The testicles should be elevated by a bandage going under them and over the thighs, and hot applications should be made. Hot sitz baths for half an hour three times daily are soothing and hasten recovery. If the symptoms are severe, epididymotomy may be performed. This immediately relieves pain and hastens recovery.

In a few days the acute stage passes. The urethral discharge is then likely to recur, but local treatment of the urethra must be resumed only after a considerable period of rest and with the greatest caution. A suspensory bandage should be worn until the patient is entirely well. There is in these cases a chronic inflammatory exudate in the epididymis, which in time often disappears. Massage of it may hasten its absorption.

PROSTATITIS

Acute Prostatitis.—The indications are (1) to lessen the severity of the posterior urethritis; (2) to prevent suppuration of the prostate; (3) if pus forms, to evacuate it promptly by incision.

The patient should be put to bed, sandalwood oil administered, and, if necessary, the pain and tenesmus controlled by opium suppositories. Locally either an ice-bag or hot poultices are applied to the perineum, a safe guide for the choice between hot and cold applications being the amount of comfort which is given to the patient. Hot sitz-baths of from one-half hour to an hour's duration two or three times daily are always indicated. Irrigation of the rectum with hot normal saline solution for half an hour at a time may be used instead. A rectal prostatic irrigator or in its absence a return flow catheter is introduced into the rectum, and a continuous flow of normal saline solution, as hot as can be borne, is passed through it.

If retention of urine should occur, it may be necessary to introduce a catheter, but this should be done only when absolutely necessary. Before catheterizing, the urethra should be well irrigated to free it from pus. One c.c. of 2 per cent. cocain solution may be injected into the urethra to relieve pain and facilitate catheterization.

Prostatic Abscess.—When a very limited area of suppuration of the prostate is present, involving perhaps two or three of the prostatic tubules, the temperature is only slightly elevated, and the local symptoms are not marked. After two or three days the temperature becomes normal and the tenesmus and frequent urination disappear. In such cases an incision into the prostate is not required, for the minute abscess generally ruptures into the urethra and the sinus fills in by granulation.

If, on the contrary, the symptoms do not improve within the first week, but the fever continues, the local symptoms grow worse, and rectal examination shows an increase in the size of the inflamed prostate, it is evidence that an abscess is forming. This serves as an urgent indication to evacuate the pus; for if the pus is allowed to break through the capsule of the prostate, it will burrow through the tissues and may cause urinary infiltration and pyemia, or, at least, a fistula which will not heal without operation. In these cases immediate surgical measures are indicated.

Chronic Prostatitis.—In almost every case of chronic gonorrheal urethritis the prostate is found to be involved. Aside from its frequency, chronic prostatitis is perhaps the most important complication of gonorrhea; for the reason that the gonococcus, with all its infectious qualities unimpaired, may be retained for years in the diseased tubular glands of the prostate without its presence being suspected. Probably most of the cases in which wives are infected with gonorrhea by their husbands come from uncured prostatitis. Chronic prostatitis is also important on account of the profound disturbance of the nervous system and the impairment of the sexual function, which it occasionally produces.

Chronic prostatitis frequently originates in an attack of acute prostatitis, or it may be the result of a slow insidious extension through the prostatic ducts of an inflammation from the posterior urethra.

It is important in the treatment of chronic prostatitis to secure the confidence of the patient and encourage him by explaining that his condition is one which can be cured; that he is not impotent or likely to become so, and that his nervous disturbances are due to a purely local condition which is not dangerous. At the same time he should be informed that the treatment calls for great patience on the part of both physician and patient, and may extend over several months.

The first indication is to improve the general condition of the patient by a proper regimen. Constipation is generally a prominent symptom, which is best treated with saline cathartics, because they have some effect in relieving pelvic congestion. All sorts of erotic excitement should be interdicted on account of their effect in inducing congestion of the prostate. Coitus should not be permitted, both because of its ill effect on the diseased prostate and because of the certainty of spreading the infection.

The most useful local measure is the emptying of the prostatic tubules of their retained and thickened contents by rectal massage, practiced two or three times weekly. In this procedure both lobes should be massaged from above downward and the manipulation should not be very vigorous, the object being to force out the prostatic contents by moderate pressure. Massage of the prostate is not well borne by all patients; and, if it produces irritating symptoms, it should not be persisted in. In order to lessen the danger of epididymitis from prostatic massage, it is advisable to irrigate the urethra and fill the bladder before massage. For this purpose, if gonococci are present, a solution of silver albuminate, 1 : 1,000, should be used; if they are absent, solutions of silver albuminate, 1 : 4,000, or oxycyanid of mercury, 1 : 4,000, may be employed.

Treatment by massage may be persisted in until improvement in prostatic symptoms ceases. At this point it is advisable to stop treatment for a month. If after this intermission the remaining evidences of prostatitis have not disappeared, a course of massage may be repeated.

Most cases of prostatitis suffer from chronic posterior urethritis, and it is important not to overlook this condition. If there is a great deal of catarrhal inflammation, with much pus formation, irrigations are advisable. But, if the suppuration is only slight, instillations into the posterior urethra are indicated. In most cases 1 per cent. or 2 per cent. of silver nitrate solution may be used, but in old and obstinate cases stronger solutions are called for and the strength may be gradually increased to 5 per cent. Strong solutions can be better applied through the urethroscope.

In nearly every case of chronic prostatitis the verumontanum is diseased and requires particular attention. The best method of treating it is to apply a strong solution of silver nitrate — 20 per cent. — directly on it through the urethroscope. Some reaction follows this application, the discharge increases, and the patient has frequent urinations, often followed by bleeding. After eight or ten days it is safe to make another application. Tincture of iodin may be used if the silver nitrate causes too much pain. After half a dozen strong applications, the verumontanum will probably return to normal; but if chronic posterior urethritis with prostatitis has existed for a long time, a submucous infiltration will have occurred, which also demands treatment by posterior dilatation.

SEMINAL VESICULITIS

Acute Seminal Vesiculitis.—The general treatment of acute vesiculitis is the same as that for acute prostatitis, with which it is usually associated. Injections into the anterior urethra, of course, are contraindicated; but above all things, any attempt at massaging or stripping the vesicles should be avoided.

Chronic Seminal Vesiculitis.—Chronic vesiculitis may originate from an acute attack of vesiculitis which does not undergo resolution; but as a rule it develops insidiously, as the result of the extension of a chronic inflammatory process which begins in the posterior urethra and extends through the ejaculatory duct. The ejaculatory duct is never occluded by the changes; throughout the whole course of the disease it remains patulous, and sterility does not occur from this cause.

Chronic seminal vesiculitis presents itself in two variations:

1. Atonic vesiculitis, in which there is chiefly an atony of the muscular fibers composing the walls of the vesicle.
2. Inflammatory vesiculitis, in which the walls of the vesicles are thickened and indurated as a result of inflammation, which may be simple, gonorrheal, or tuberculous in origin.

Either form of vesiculitis may exist by itself; but usually there is a combination of atony and inflammation of the vesicular walls.

Treatment.—The treatment consists in stripping or expressing the contents of the vesicles once in five to seven days. Stripping empties the vesicles of their inspissated contents, without forcing the muscular fibers to contract; and, by the relief of distension and the rest thus afforded them, the muscles recover their tone. The inflammatory thickening around the vesicle is absorbed as a result of massage.

Contraindications to stripping are: (*a*) the existence of acute vesiculitis; (*b*) blood in the expressed material, or (*c*) excessive tenderness. With these conditions present, there is always danger of setting up an epididymitis.

In chronic vesiculitis the posterior urethra should not be overlooked, but should receive treatment, with irrigations or instillations or by applications made through the urethroscope as outlined under chronic prostatitis. It is desirable, however, not to apply local treatment to the posterior urethra and massage the vesicles at the same sitting, but rather to allow a couple of days to intervene.

The duration of treatment must be protracted, for it requires from two to twelve months to effect a cure. In obstinate cases characterized by marked sexual neurasthenia or intractable gonorrheal rheumatism, free incision into and drainage of the seminal vesicles may be demanded. This is a procedure requiring expert skill.

GONORREHEAL INFECTIONS OF SYNOVIAL MEMBRANES

The most frequent metastasis of the gonococci is seen in the infection of the synovial membranes (arthritis, teanosynovitis, bursitis), usually developing in the third week of the disease, after involvement of the posterior urethra. Traumatism may be a predisposing cause in this condition.

It is well in this group of cases to call in an orthopedic specialist for the local treatment of the infected joint. But it must not be forgotten that the most important factor in treatment consists in the removal of the foci of infection in the urethra or its adnexa.

The treatment should be carried out along the lines already suggested for the treatment of these lesions. Vaccines are efficacious in some cases, in others operation for drainage of the seminal vesicle or prostate may be indicated; this latter requires special skill in genito-urinary surgery.

GONORRHEAL OPHTHALMIA

EVERY CASE OF ACUTE CONJUNCTIVITIS IN A GONORRHEAL PATIENT IS A CONDITION REQUIRING EXPERT ATTENTION, AND SHOULD BE IMMEDIATELY REFERRED TO AN OPHTHALMOLOGIST.

HOME-CANNED FOODS AND BOTULISM

The still widespread belief that food poisoning of the sort attributable to bacterial products taken in with the food is associated almost exclusively with animal products seems to demand correction, particularly at present. A warning of the unsuspected danger of poisoning from canned vegetables at a time when the food conservation propaganda has led to the preservation of foods of all kinds in thousands of homes in anticipation of the winter's needs has been uttered by Dickson[1] in a recent issue of The Journal. He asserts, on the basis of an investigation conducted at the Stanford University School of Medicine, that the frequency with which food poisoning is caused by the presence of the toxin of the *Bacillus botulinus* is probably very much greater in this country than has been generally believed.

This kind of food poisoning has most inaptly been termed botulism, in recognition of the assumption that it is due as a rule to the ingestion of infected sausage (*botulus*). The insidiousness of the menace is emphasized by the fact that food in which the offending micro-organism, the *Bacillus botulinus*, which produces the harmful toxin, has grown may not give any indication of being altered in a way that necessarily arouses suspicion. It should be clearly understood that botulism is an intoxication, not an infection.[2] Unlike most bacteria dangerous to man, the *Bacillus botulinus* appears unable to grow in the human body, and its injurious effect is therefore limited to the action of the toxin produced in foods outside the body. Fortunately this toxin, as it is currently stated, is readily destroyed by heat; hence there is a safeguard of the utmost value in serving only after heating all foods in which the danger may lurk.

The investigations of Dickson have now brought to light an unexpected number of known and hitherto unrecorded cases of botulism occurring in the United States. This author has become convinced from his experiences that there have been many more outbreaks which have passed without recognition, and that if it were possible to follow up all cases of food poisoning in which the patients recovered, and all fatal cases in which the death certificates give the cause of death as ptomain poisoning or bulbar paralysis, a very large group of instances would be collected. Home-canned vegetables and fruits have often been the carriers of the danger. Dickson's work emphasizes what has been demonstrated before, namely, that not only can the micro-organism be grown readily in mediums containing vegetable foods, but also that it is a spore-bearing form which is quite resistant to heat. Taken in connection with the fact that *Bacillus botulinus* is an obligative anaerobe so that the conditions which exist in a sealed jar are suited for its growth along with production of the toxin, this explains why improperly sterilized canned products may develop food poisoning. It is unfortunate that the widely distributed directions for the so-called "cold pack" process of canning and preserving have not given more emphasis to the need of very efficient sterilization in the process. Jordan states that, to judge from the recorded outbreaks, domestically prepared vegetables and meats are more likely to give rise to botulism than those prepared commercially on a large scale. The general use of steam under pressure in the large canning factories affords a high degree of protection against the anaerobic bacteria and their resistant spores. Whatever the method of treatment, all canned or preserved food having an unnatural appearance, taste or odor should be rejected. Reheating of all prepared foods immediately before use is an additional safeguard. Foods, such as salads, composed wholly or in part of uncooked materials should not be allowed to stand overnight before being served.

[2] A good account of botulism is given by E. O. Jordan in Food Poisoning (Chicago, 1917), from which some of the statements above are taken.

THE INHERITANCE OF STATURE

Growth is influenced by conditions that may be described as internal and external, respectively. One of the sets of factors thus concerned is constitutional; the other, environmental in character. Stature is determined by growth, and the question of the degree to which this feature of the individual is controlled by conditions of life rather than by hereditary considerations has been somewhat debated. As a recent writer[1] has pointed out, that there are hereditary factors involved in the differences in height of adults follows from the recognition of racial differences, for true racial characters are hereditary. Moreover, this hereditary nature has been popularly long recognized. Nevertheless, there is a strong tendency with certain persons to ascribe idiosyncrasies in stature almost wholly to peculiarities of conditions of development. The assumption of an inferior food supply as a cause of decreased stature in certain groups of population has often permitted its adherents to forget differences in blood in the unlike groups. The superior stature of the residents of the state of Kentucky has been ascribed to lime in the soil. The real reason, Davenport writes, why the people of Lexington, Ky., run tall is that they have a large proportion of Scotch blood, as they readily admit. One can test this conclusion by going to Scotland County, North Carolina. This is on the coastal plain where there is practically no lime. Here, at places like (Mac) Laurenburg, (Mac) Queensdale and Maxton (Mac's town) a nearly pure Scotch population is found—descendants of the Cape Fear River immigrants—and they are even taller than the people of Lexington. This experience strongly suggests that internal constitutional factors are more important than the ordinary environmental differences.

---

[1] Davenport, C. B.: Inheritance of Stature, Genetics, 1917, 2, 313.

The experimental investigations of Osborne and Mendel,[2] among others, have indicated that growth can be suppressed by inadequacies in either the quantity or the quality of the ingested food. But even after the lapse of long periods of suppression of growth, that is, control of growth by external or nutritive agents, resumption of growth may take place if the dietary conditions are rendered favorable and adequate. This represents an extreme situation in some respects; and, as Davenport remarks, overfeeding, however much it may affect weight, has probably little effect on adult stature, though it may hasten growth and thus enable a man to reach precociously his predestined stature. The comparative lack of dependence of growth on quantity of food is shown by the fact that a bantam chick which is fed heavily never develops into anything but a bantam fowl. Admittedly the activities of various endocrine glands have an influence on the continuance and extent of growth. All manner of complicated hypotheses have been framed to account for abnormal growth and variations from the expected on the basis of unusual performances of some gland like the thyroid, pituitary or pineal structures, or the sex glands. But such variations may themselves well be hereditary or racial in character.

The modern study of genetics has made it possible to approach the problem of inheritance of stature in a thoroughly scientific way. Under the direction of Davenport[1] of the Station for Experimental Evolution at Cold Spring Harbor, N. Y., the Eugenics Record Office has undertaken an analysis of the obvious fact that persons differ in height. From this it appears that there is a clear correlation, though not perfect, between the average time of onset of puberty and the average age of slowing up of growth, and it is probable that the former controls the latter. In the case of woman, for example, an examination of the curve of growth brings out the important point that the growth processes, which are fairly progressive up to about 14 years, begin to be damped off after that period. Were the average rate of growth of the female between the ages of 8 and 14 maintained up to the age of 25 years, the average woman at that age would be over 210 cm. or 82½ inches or nearly 7 feet tall. The reason we do not reach such a stature is that our growth is damped off; and the principal damping off occurs as the germ glands ripen. Variations in adult stature may conceivably result from an acceleration or a retardation in this damping off process.

According to the acquired records, very tall men tend to marry a greatly disproportionate number of very tall women (and few or no very short ones); also tall men marry a disproportionate number of very tall women; medium men tend to marry women of the various statures about in their proportion in the whole population. Short men tend to marry short women and few very tall ones. Very short men marry an excess of short and very short women, and relatively few very tall and tall ones. In a word, persons of similar stature tend to marry each other; and extremes are more particular in this respect than those of medium stature. The progeny derived from matings of similars are less variable than those derived from matings of dissimilars. Thus the offspring of two tall parents are less variable in stature than those of two short parents. When both parents are "tall" or "very tall," and of tall stock, practically all the children are tall or very tall. When both parents are "very short" or "short," and of short stock, all children are short or very short. Shortness, according to Davenport, is due to certain positive factors that inhibit growth of the various parts. He regards it as probable that in all forms of dwarfing there are multiple dominant inhibiting factors. In the case of giants, when both parents are tall all of the children are tall; this indicates that the factors for tallness are mostly recessive—probably owing to the absence of inhibitions to prolonged growth.

It is an interesting additional feature of this new study in the heredity of stature that the inheritance of proportional length of the segments of stature is as evident as the inheritance of absolute differences. According to Castle,[3] to a large extent the factors that determine size are general factors affecting all parts of the skeleton simultaneously. Whatever special factors (if any) there are, which are concerned in limiting the size of particular bones, these can play only a subordinate part in determining size. According to Castle, the chief factors are plainly general factors, and control the growth of the body as a whole. Davenport's study seems to show, however, that general factors control growth only to a degree that may be estimated as less than half. On the other hand, special factors are present that control, independently, the growth of the various elements that go to make up stature. And the graduated nature of the variations of stature must be largely due to the number of these independently varying units.

RECENT CONTRIBUTIONS OF CLINICAL CALORIMETRY

In the hands of American investigators, clinical calorimetry has yielded notable contributions. The Nutrition Laboratory of the Carnegie Institution, under the direction of F. G. Benedict at Boston, and the Russell Sage Institute of Pathology, under the guidance of Graham Lusk, have served as training stations. These endowed laboratories not only have enriched science with fundamental facts, but also have served as centers from which have gone young workers competent to appreciate what human calorimetry really means and to spread an interest in what it can contribute to medical progress.

The basal metabolism of normal man has been well established by the large number of carefully conducted measurements made in this country. It is not proportional to the body weight of the individual, but rather to the superficial area, as Rubner enunciated long ago. The universality of this conception is shown by the outcome of a large number of determinations showing that the unit of surface area eliminates the same amount of heat in the normal adult within 10 per cent. of a determined average. For adult men approximately 40 calories per square meter of body surface per hour may be accepted as approximating closely the normal basal heat production when the individual is resting and before administration of food in the morning. A thin person may produce 50 per cent. more heat per kilogram of body substance than an obese one; yet when the heat output per square meter of surface is calculated there will be little difference. The nitrogen content of animals has been shown by Moulton[1] to be almost exactly proportional to the surface area of the subject. Lusk[2] points out that if the nitrogen content is a measure of protoplasmic tissue, these experiments afford a striking confirmation of the doctrine of Voit that the heat production is proportional to the mass of living cells. In any event, thanks to these researches, the validity of the use of properly calculated heat output per unit of surface, that is, of basal metabolism, as a criterion of an altered metabolism in patients has now been established.[2]

Aub and Du Bois[3] have properly pointed out that in order to establish more fully the law that the total body metabolism is proportional to the surface area, it is important to establish the law not only for persons of normal size and shape, but also for those who are deformed. If the body surface is a tone index of the metabolism, Aub and Du Bois add, and if the body surface is accurately measured, then dwarfs or men with their legs cut off would show proportionately the same basal metabolism per square meter of surface as do normally shaped persons. This has been found to be the case in the subjects with apparently normal endocrine systems who have been examined in the Sage calorimeter, so that the law of surface area holds good for men of unusual body shape. However, dwarfs with involvement of the ductless glands and symptoms of cretinism showed a marked reduction in metabolism below the average found in normal cases, as has been reported by other authorities.

Age is not without influence on metabolism. Boys just before puberty have a high chemical exchange, so that their basal requirement may be as much as 25 per cent. above that of the adult. Men have a higher metabolism than women. With advancing age, however, there is no longer the same intensity of oxidation as in the prime of life. Aub and Du Bois[4] have studied in the calorimeter a group of six men between the ages of 77 and 83. Their average basal heat production was 35.1 calories per square meter per hour, which is 12 per cent. below the average for men between the ages of 20 and 50.

The most recent series of contributions in clinical calorimetry with the Sage calorimeter[5] present interesting additions to our knowledge of metabolism in disease. Edematous nephritics were found by Aub and Du Bois to manifest a diminution of the body metabolism, according both to body weight and to surface area. In two patients with great edema the heat production was 27 and 40 per cent. below the normal average. Such nephritics kept on low diets show a reduction in food requirement similar to that usually found in prolonged undernutrition. This is in contrast with the experience on patients suffering from other types of nephritis for whom the basal metabolism and the food requirement seems to be normal. Cardiorenal disease associated with dyspnea may manifest a distinct rise in the heat production.[6] It is interesting to note further that no relationship could be established between the level of metabolism and the degree of acidosis or the eliminative power of the kidney. Aub and Du Bois mention that the normal respiratory quotients found in patients with low carbon dioxid combining capacity of the blood plasma prove that nephritic acidosis is not caused by difficulty in oxidizing carbohydrates.

An illustration of the value of calorimetry in elucidating the action of drugs is afforded by the study of Means, Aub and Du Bois[7] on the behavior of caffein. They remark that as one looks over the enormous literature on the various actions of caffein, one gains the impression that the numerous contradictory statements are not necessarily due entirely to faulty observation, but possibly because the action of caffein on any given function is extremely variable, often diametrically opposite, in different individuals, and in the same individual with varying doses. However, after taking large doses of the alkaloid (from 8 to 10 grains, or 8.6 mg. per kilogram of body weight), normal individuals exhibited an increase in the basal metabolism of from 7 to 23 per cent. without significant change in pulse rate, body temperature, or the proportions of the various foodstuffs metabolized. This unique effect of large doses of caffein seems remarkable; but, as Lusk[3] has pointed out, it is slight compared with the stimulation of metabolism by muscular exercise. It is great only by comparison with "the immutability of the level of the normal basal metabolism, a state in which the heat production is subservient to the requirement of energy on the part of the cells for the maintenance of life, the requirement being so regulated and adjusted that the heat loss per square meter of surface is approximately 40 calories per hour, while the body temperature is maintained at a constant level."

BEER AS A SOURCE OF PROTEIN

Malted liquors are defined as beverages made by the alcoholic fermentation of an infusion of barley malt and hops, with or without unmalted grains. Beer, which belongs in this category, ordinarily contains from 3.5 to 4 per cent. of alcohol. The idea long held by a large portion of the public that "alcohol increases the power of endurance, and gives greater energy and ability to work longer" has given way to a more accurate appreciation of the real rôle of this substance in the body. Despite the fact that alcohol can be burned in the human organism, the most enthusiastic supporters of its use, if there still be such, do not defend it on the basis of superior nutrient virtues. The pharmacologists almost without exception rank alcohol as a depressant rather than a stimulant in the true sense; and the therapeutist who cares to advise the employment of alcohol does so from the standpoint of its pharmacodynamic performance rather than because of any superior food value in the product.

Beer, however, has made claim to recognition as a food, in contrast with the distilled liquors that contain essentially only water and alcohol, on the basis of the cereal constituents which are still contained in it. Hence the statement that "beer is liquid bread." In addition to alcohol, beer does, in fact contain sugars and other soluble carbohydrates, along with a small amount of nitrogenous compounds that are frequently expressed as protein. The customary method of arriving at an estimate of this fraction of beer consists in determining the nitrogen content and calculating it as protein, after multiplication with the familiar factor N × 6.25. This procedure is now well recognized by food analysts to be fallacious so far as it assumes that all compounds containing nitrogen, in food substances, are actually protein in nature. On this basis such substances as amins, ammonium salts, alkaloids, etc., would be counted as protein.

The uncertainty regarding the real food value, if any, of the nitrogenous compounds of beer is emphasized in a recent report of the Committee of the Royal Society on the Food Supply of the United Kingdom. which has assumed, without any conclusive evidence, that something between 50 and 100 per cent. of the nitrogen is in the form of protein or amino-acids which are utilizable in the body. In the Department of Physiology of Glasgow University, Sharpe[1] has recently undertaken to throw further light on the controverted question of the nature of the nitrogenous compounds in beer. He reviews the fate of the proteins of barley during the brewing process wherein, as a result of the malting, part of the protein in the grain is acted on by proteolytic enzymes which break it down into simpler substances. These, along with a little soluble protein, pass into solution during the mashing; but the greater part is left in the brewers' grain. During the processes of boiling, hopping and subsequent cooling of the wort, some of this protein becomes precipitated. The amount of nitrogen thus finally left in solution is termed by the brewer "permanently soluble nitrogen." By the action of the yeast during fermentation, a further quantity of soluble nitrogen is removed by these organisms' using a certain proportion as food. A further amount of protein is removed after the beer is made, and this process is carried out to insure that the beer may remain "bright."

Beers of various types contain solid matter ranging from less than 4 per cent. in the "light" varieties to over 6 per cent. in other kinds. Of this, about one half is carbohydrate, essentially dextrin in nature. This leaves 2 or 3 per cent. of the dissolved substance, some of which is nitrogenous, to be accounted for. That the protein content of the beer or ale will not be appreciable when the beverage reaches the consumer is shown by the failure of most of the protein tests to give a reaction with the product. According to Sharpe's new analyses, the protein nitrogen of the beers analyzed varies from 13.2 to 37.0 per cent. of the total nitrogen, that is, the protein content of beer varies from 0.038 to 0.185 per cent. The nitrogen as amino-acid varies from 25 to 46 per cent. of the total nitrogen, that is, the amino-acid nitrogen of beer varies from 0.014 to 0.040 per cent. There is a varying proportion of nitrogen combined as purin compounds which in some cases exceeds that combined as amino-acid nitrogen. It varies from 25.8 to 52.4 per cent. of the total nitrogen, or from 0.01 to 0.39 per cent. of the beer itself. The undetermined nitrogen of these beers varies from 2.4 to 6.3 per cent. of the total nitrogen, that is, the percentage of the beer itself varies from 0.001 to 0.005.

---

[1] Sharpe, J. S.: The Distribution of Nitrogen in Beer, Biochem. Jour., 1917, 11, 101.

Bearing in mind the limited quantities of beer that can be taken per day with any approach to impunity, it will be seen that the few grams of hypothetic protein thus offered have no significance whatever as a defense for the use of the beverage. One might as well exploit the protein in ginger ale or fruit juices. A writer[2] on dietetics has thus presented the possible use of the malt liquors:

> Beer, ale, and stout, by virtue of their taste, aromatic bitters and tonics, give a relish to food, increase appetite, and promote the flow of saliva. To this extent they assist digestion. They are useful to convalescents, those enfeebled by chronic diseases, and the aged. They are of some value to those whose occupation is sedentary, whose stomach has lost tone by overwork, rush, and worry, and to sufferers from neuralgia and insomnia. The limit should be 1 pint a day. They are contraindicated in neurotic conditions, diabetes, gout, rheumatism, obesity, and genito-urinary diseases.

We leave it to our readers to steer a safe course, if there is any, between the indications and the contraindications for beer. In any event, any claim for its protein contribution to the diet no longer needs serious consideration. The dairy cattle are more fortunate in having the protein concentrate of the brewers' grains available for their ration.

Current Comment

THE INCIDENCE OF TUBERCULOSIS AMONG SOLDIERS

When Major Eduard Rist of the Medical Corps of the French Army, assigned by the French government to the Surgeon-General's Office, announced at the meeting of the American Association of Military Surgeons held at Fort Benjamin Harrison this week that the facts concerning tuberculosis in France, and especially in the French army, do not agree with the exaggerated statements published in this country, he settled conclusively a point which has agitated civilian and medical tuberculosis authorities in this country since the beginning of the war. Major Rist stated that out of 1,000 men sent back to a base hospital as suffering with pulmonary tuberculosis, all but 193 were returned to the front with the diagnosis not confirmed. He said also that the chief cause of the too numerous diagnoses of tuberculosis was the fact that civilian physicians called to army life are too much inclined to make the diagnosis of tuberculosis on very slight evidence. In making a differential diagnosis the mistakes were not made through the difficulty of differentiating pulmonary tuberculosis from unusual maladies, such as abscess of the lung, or pulmonary tumor, but far more frequently through the confusion of the diagnosis with minor complaints such as infections in the upper air passages, acute rhinitis, pharyngitis and bronchial inflammation. France, in need of every soldier, found it necessary to comb with a fine comb in order that no man be eliminated from the army through a mistaken diagnosis of this sort. The United States, with a supply of men far above the number that can be successfully trained and transported for military service, need not, perhaps, be so careful in eliminating men from military service because of the suspicion of this disease. In any event, making a diagnosis of tuberculosis and eliminating a man from military service for this cause wrongfully is not doing justice either to him or to the nation.

ISOPATHY

The early stages of homeopathy are associated with certain apparently minor developments of no little interest from the historical point of view. Not wholly satisfied with the doctrine expressed by "similia similibus," Hering, Lux and others urged the principle of "aequalia aequalibus curantur"—the like cures the like. The form of treatment indicated in this slogan was regarded not as a new departure, but rather as the revival of methods found in folk medicine, and mentioned by early writers and even by church fathers, especially the holy Bishop Ivo of Chartres, whose remarkable statement on the analogy between Christ and the skilled physicians, made in 1092, runs as follows:[1]

> It is, namely, the habit of people skilled in medicine to cure at one time by opposites, and at another by likes, the illnesses which they undertake to cure. This is what our Lord Jesus Christ did, making us rich by his poverty, exalting us by his humility, healing us by his infirmity, giving us life by his death. In the same way, in medical theory, dry is set against moist, moist against dry, hot against cold: and contraries of lesser strength are overcome by the bringing in of contraries of greater strength. In similar fashion like is apposed to like, when the length or breadth of the poultice is measured by the amount of the wound or swelling. So scorpions' flesh boiled in oil heals the stings of scorpions; so a remedy made from the flesh of a serpent operates against the bite of a serpent, and, taken in a drink, overcomes poisoned drinks. In the same likeness our Physician healed by his own death in the flesh the death of our flesh which came from the serpent. . . . But with this remedy made up of the like was mixed also the remedy made of the opposite. For here obedience healed what disobedience had there corrupted; and what had there been contaminated by the pleasure of appetite is here made right again by the suffering upon the cross.

We are told[1] that the isopathic principle of treatment was carried out by its adherents in the most exact manner possible. For smallpox, matter taken from the pustules—"variolin"—was given internally; itch was treated internally with "psorin" or scaly material from parts affected with scabies; sweating of the feet with foot-sweat; phthisis with "phthisin"; caries of the teeth with "odontonekrosin"; diseases of the liver with "hepatin"; diseases of the spleen with "lienin"; diarrhea with fecal matter; teniasis with tapeworm joints; gonorrhea with gonorrheal pus—a treatment for gonorrhea recently urged again as a new advance by a homeopathic physician in New York. In the end it even was demanded that the remedy must come from the patient's own body—

[1] Quoted by Faye, Nord. med. Ark., 1880, **20**.

auto-isopathy — and autocankrin was given in cancer, auto-odontonekrosin for dental fistula, etc. The reference in the remarkable statement by Bishop Ivo to the use of the flesh of scorpions and serpents in stings and bites by these animals reminds us again that in the early ways of treating the conditions resulting from the bites of poisonous animals we see the first foreshadowings of the present conceptions of immunity and the treatment based thereon. Probably what is usually called crude empiricism has had more to do with the evolution of those conceptions and methods of treatment, preventive and curative, than ordinarily recognized.

"SCIENCE"

> ". . . the only difference between the hypochondriac and the consumptive is, that the one suffers from what the world would term a purely mental disease, imagining himself unwell, whilst the other has, unconsciously, thought himself into a condition of one of the many phases of disease."

So, editorially, speaks the *Christian Science Monitor* of recent date. This also, we opine, is the only difference between the soldier suffering from "shell shock" and the one who has had a leg blown off. For the Christian Scientist, germs do not exist; the tubercle bacillus is but a creature of the medical man's disordered fancy. The unreality of a germ as distinguished from the materiality, let us say, of the two dollar bill which a Christian Science practitioner exacts for an "absent treatment" is based, presumably, on the fact that one can be seen only through a microscope while the other is visible to the naked eye.

MILK PRODUCTION

At a time when much interest centers in the preservation of our dairy cattle from the temptation of disposing of them profitably as sources of beef, it is important to count the cost which the rearing of milch cows to their highest productivity really entails. According to reports of German experience, since the war began about 10 per cent. of the dairy cattle have been slaughtered each year. At best there are probably not more than 20,000,000 productive dairy animals in this country at present. Next in importance to the integrity of the bread ration in the household is the maintenance of the normal milk supply, as already pointed out in The Journal.[1] The number of milch cows is only one measurement of milk production; the productivity of the individual cow is the other. At the present time the average milch cow supplies 4.5 individuals in this country. Pearl and Patterson[2] have pointed out the fact well known among dairymen and breeders that, other conditions being the same, a cow will produce more in a given length of time during her second lactation period than for the same time during her first period; she will produce more her third lactation period than her second, and so on until she reaches mature form, or the age for maximum production. She remains in this mature form for a few years; then each succeeding lactation period decreases in the rate of milk flow. Opinions differ somewhat as to the average age at which a cow reaches mature form, and as to the rate of increase with which she approaches that form. The general belief is that mature form is reached by the fifth year. An investigation of the records of American Jersey cattle—a typical milk-producing breed—has verified the fact that milk production changes with age in a definite manner. Maximum production is reached at approximately the age of 8 years and 7 months. The long time, measured in years, required to procure the highest efficiency should serve as an added warning against permitting the unwise slaughter of such slowly developing potentialities. For, after all, beef is not the sole wholesome food available.

DRINKING FOUNTAINS—SANITARY AND INSANITARY

Last year we referred to the unexpected menace to health which the modern type of so-called sanitary drinking fountain may harbor.[1] That this is not merely an academic assumption, but may become a dangerous actuality, was borne out by the occurrence of a streptococcal infection that was traced directly to a drinking fountain.[2] Although nozzle fountains are being installed in large numbers throughout the country, there is little evidence, if one may judge from the forms everywhere displayed, that the defects of the types now furnished are either corrected or recognized. In the earlier investigations it was pointed out that the vertical jet of water permits micro-organisms derived from the mouth of the drinker to dance in the stream like a ball in the jet of a fountain, so that the bacteria may remain undisplaced for unexpectedly long periods. Dr. Whittaker[3] of the Minnesota State Board of Health has since completed an investigation of seventy-seven drinking fountains representing fifteen commercially obtainable types. About two thirds of these were of the continuous-flow type and one third of the intermittent type operated by the consumer. The nozzles on all discharged vertically, and the height of the water jet above the parts that could be touched by the lips of the drinker was less than one inch in nearly half of the fountains. All were subject to contamination by the consumer, either directly by the lips or by water falling back from the lips on the jet or surrounding parts. Certain of the types have closed cup-shaped receptacles around the point of discharge which were demonstrated to retain added coloring mater — and therefore bacteria also — for long periods of time. The crucial test of danger comes in the bacteriologic examinations conducted on these fountains. Eighty per cent. of those in use at the University of Minnesota were found infected with streptococci; and the water from 11 per cent. contained organisms of this type when they were not found present in the water supplied to the fountains. As Whittaker says, these results indicate clearly that drinking fountains may be a factor in the transmission of communicable diseases. There is nothing discouraging about this, however; for it has already been demonstrated that the existing conditions can be remedied by the introduction of fountain nozzles that are safe from a sanitary standpoint and are economical to construct and operate. The change of construction merely involves the substitution of an inclined nozzle for the vertical jet, and the protection of the point of discharge from the approach of the consumer.

THE MEDICAL EXAMINATION OF THE NATIONAL ARMY

The announcement has just been made from Provost-Marshal General Crowder's office in Washington that in examining the remainder of the 10,000,000 men subject to draft and service in the National Army, information will be sought first as to the liability of each man for service, and the physical examination will follow only when the man is not exempt for some cause under the law. This is so obviously the correct order of the steps in the selection of men for service that it is surprising that this method was not adopted in the calling of the first 700,000 men.

THE IMPORTANCE OF MOUTH SPRAY INFECTION

Under conditions that involve the close association of large numbers of persons, as in the great military encampments, certain modes of infection acquire a kind of exaggerated importance. The transmission of disease germs in ways that are rare in normal everyday life occurs with greater frequency and has more far-reaching consequences. Exposure to inhalation of mouth spray is one of the most serious dangers. The small droplets discharged from the mouth or nose in sneezing, coughing, laughing and loud talking float about in the air for some time, and may be carried by currents of air to a considerable distance. There is reason to believe from the experiments of Köhlisch with tubercle bacilli that the moist droplets which often contain a little mucus are more likely than dry dust to produce infection. Köhlisch, for instance, found in animal experiments that fifty tubercle bacilli inhaled as bacterial spray produced over twenty lung nodules, while the inhalation of over 2,000 in the form of dry dust had a very irregular action, and in some cases evoked no pathologic change. It is a somewhat general belief that, in human tuberculosis, infectious droplets are a more frequent source of infection than dried sputum. In numerous other infections that enter by way of the respiratory tract, the inhalation of mouth spray coming from an infected person or healthy carrier seems the typical mode of infection. This is true in diseases like pneumonia, influenza and whooping-cough, and probably in measles. Epidemic meningitis is probably also most commonly spread in this way. The importance of mouth spray in surgical wound infection is well known. In camp life, infection of this sort is notably difficult to control. The rapidity with which measles and epidemic meningitis are likely to spread among new recruits is typical. Possibly increase of tuberculosis among troops is partly due to the increased opportunity for infection as well as to the influence of predisposing factors. It is doubtful whether hygienic instruction in the use of the handkerchief for smothering mouth spray from the particularly mischievous sneezes and coughs would be immediately effective, although every hygienically trained individual is a help toward the desired end. General camp measures that promote resistance to infection are always of value, probably especially so in meningitis, less of course in measles. If it were possible in cases of "cold" and the like in the incipient stage to make examinations, and when necessary, to isolate the patients, the spread of mouth spray infection might be materially checked. This measure is worthy of consideration in all conditions in which there is any definite and serious respiratory tract epidemic. Known contacts may be kept under special surveillance and the cooperation of officers enlisted to detect early signs of infection. There is no single and universally applicable method for preventing the transference of germs from one soldier's respiratory tract to another's, but all reasonable and persistent attempts to prevent mouth spray infection are worth making. A person with the developed rash of measles or the skin-peeling of scarlet fever is not allowed to roam unchecked, if his condition is known; but little or no restraint is yet put either by health authorities or by public opinion on the wanderings of the much more dangerous person who is sneezing and coughing myriads of germs into the atmosphere.

THE BELGIAN AND FRENCH PHYSICIANS' FUND

We recently attempted to emphasize the appeal for funds for physicians of Belgium and Northern France who need aid in various ways. Dr. Keen acknowledges in this issue of The Journal the contributions to this fund thus far received. There are only sixteen contributors in this first list; there ought to be sixteen hundred, and there would be—and many more than this number—if the actual conditions among our professional brothers on the other side were realized.

War Dietary and Scurvy.—The death of a patient from scurvy in the Poor Laws hospital in Glasgow prompted the investigation of the occurrence of scurvy. This was deemed important in view of the enforced changes in diet of many people on account of war conditions. The investigations disclosed that under normal conditions three or four patients with scurvy are admitted to each of the Poor Laws hospitals each year. Since the middle of February, 1917, however, according to an article in the *Medical Officer* (London), fifty patients with scurvy have been admitted. It is said that all of these cases occurred in males, and appeared to occur only in men who live in model lodging houses or who live alone. This it is said suggests improper selection and preparation of food. The superintendent of one of the hospitals believes that the shortage of potatoes has much to do in the occurrence of scurvy, this being the only fresh vegetable customarily used by this class of patients.

Medical Mobilization and the War

PHYSICIANS RECOMMENDED FOR COMMISSION IN RESERVE CORPS

During the week ending Sept. 29, 1917, 522 physicians were recommended for commission in the Medical Reserve Corps, the proportion being six majors, seventy captains and 446 lieutenants.

During the week ending Oct. 6, 1917, 252 physicians were recommended to the Adjutant-General of the Army for commission in the Medical Reserve Corps, the proportion being one major, twenty-seven captains and 224 lieutenants.

NEWS OF THE CANTONMENTS

[From Our Special Correspondents]

Camp Pike, Ark.

Camp Pike, the location of the Eighty-Seventh Division of the National Army, is situated in the hills about 5 miles north of Little Rock. The camp itself occupies a fairly level spot cleared from a forest of small oak. The surrounding scenery is very beautiful. The camp is largely completed as far as buildings are concerned, but the roads and the walks for foot passengers have yet, to a great extent, to be finished. An area about 2 miles long by 1 mile wide would contain the main portion of the camp.

The great army of drafted men are coming in, a few hundred daily, and the physical examination is being done in thirteen regimental infirmaries. So far about 18,000 men have been examined. The last increment consisted of 1,600 colored men, who were handled entirely by Regimental Infirmaries 1 and 2, depot troops. The commissioned medical personnel doing this examining was largely taken from the training school at Fort Riley, Kan. About thirty-five medical officers of the Reserve Corps have handled this 18,000 and have entered on their duties with energy and dispatch. All men requiring further examination have been sent to a board of specialists especially designated for that service at the base hospital.

THE BASE HOSPITAL

The 1,000 bed base hospital at this point under the command of Major A. P. Upshur, M. C., is a group of one story buildings, the floor space of which covers over 20 acres. It takes an hour of casual inspection to walk through it. The health of the command at present is good, and the hospital had only a little over 100 admissions during the past week. There has been some measles in the command, but nothing of a serious nature. While Camp Pike has had a rather high malarial rate in the past, every effort is being made to prevent the breeding of mosquitoes in this locality, and the work is being pushed by Major Charles E. Freeman, M. C., who is sanitary inspector for this division. Camp Pike is very well drained, and the water supply is excellent.

Under the leadership and direction of Lieut.-Col. Robert M. Thornburgh, the medical work of the division is rapidly assuming the proportions of a well oiled and well operated machine. Major Russel R. Jones, M. R. C., recently ordered here from Fort Oglethorpe, where he has been since June 1 as an instructor in the M. O. T. C., arrived a few days ago and assumed his duties as assistant to the division surgeon.

PROBLEMS OF THE DIVISION SURGEON

The problems confronting the division surgeon in the opening and establishing of his office are multitudinous, multifarious and never ceasing. Men of every station and grade, from the millionaire to the pauper and from the highly intellectual to the moron, come trooping daily down the streets of Camp Pike to meet their fate at the hands of the hard working crew of medical officers, who a few months before were leading the independent life of the civilian physician. To select the true from the false, the mentally weak from the mentally strong, the crippled from the well, the sightless from the seeing, and to do no injustice to any one has certainly taxed the mental and physical energies of the examiners to the utmost. There is a general impression that at least here there were few exemptions. The lame, the halt and the blind have come here to have it decided whether of such material could be made the "little buck private" of the U. S. Army. Men have come into Camp Pike, led by hand, with wooden legs, in the advanced stages of pulmonary tuberculosis, feebleminded and insane, and with every imaginable condition and physical deformity of the most pronounced character. Paralytics and epileptics are not uncommon. There are a great many things about these men that arouse one's sympathies. Occasionally one comes in bringing his whole family and part of his wife's relations along.

THE SANITARY TRAIN

The Sanitary Train of the Eighty-Seventh Division has received about half its enlisted quota. Lieut. R. H. Davies of Fort Riley, Kan., and Chicago is in charge of Provisional Field Hospital No. 1, and Lieut. J. B. Steele of Fort Riley, Kan., and Chattanooga, Tenn., is in charge of Provisional Ambulance Company No. 1. Lieutenants Davies and Steele are unofficially directing the field hospital and ambulance work, respectively. Recent additions to the sanitary train are Red Cross Ambulance Company 44 of Topeka, Kan., with five officers and 118 men, in charge of Lieutenant Lerrigo, and Red Cross Ambulance Company 39 of Mississippi, with thirty men and no other officers, in charge of Capt. Nolan Stewart. Provisional Field Hospital No. 1 has its full equipment, and there is now complete equipment here for two ambulance companies. The sanitary train is to be completed as regards personnel at an early date.

The regimental infirmaries of the Eighty-Seventh Division are all fully equipped and are handling their work in a thorough and efficient manner.

A recent promotion was that of Capt. Amos Gale Straw of the roentgen-ray department at the base hospital to the grade of Major.

Camp Wheeler

106TH SANITARY TRAIN, 31ST DIVISION

The train now consists of Field Hospitals Nos. 121 (Florida), 124 (Alabama), and 122 and 123 formed from equal division of Georgia Field Hospital No. 1. Numbers 121 and 123 are designated as motor companies and 122 and 124 as animal drawn. Major George L. Keenan, M. C., N. G. (Mass.), commands the section.

Ambulance Company No. 1 of Alabama has been divided into four equal parts, each the nucleus of Ambulance Companies Nos. *121, 122, 123, 124,* two motor and two animal drawn; Major Job Patterson, M. C., N. G. (Ga.), commands the section.

Many of the officers' families have arrived and taken permanent quarters in Macon, and are interesting themselves actively in Red Cross affairs.

The members of the orchestra of the Florida Field Hospital (No. *121*) are the recipients of much favorable comment on their work. They merit it.

Last week a pleasant social was held, introducing the ladies of the train. Supper was served in one of the large mess halls after which the Florida Hospital orchestra played for dancing until 10:30. It is the intention of the train to make these socials a weekly affair on Wednesday evenings. The guest of the evening was Lieut.-Col. Louis C. Duncan, M. C., U. S. Army, division surgeon.

The camp hospital has now assumed large proportions and its conduct and management under Major Lorne A. Greene, M. C., N. G. (No. 12) is the wonder of visiting officers, Red Cross officials and civilians. The aid of the Red Cross of Macon has been of invaluable assistance, and their donations of pillows, sheets and delicacies have certainly been appreciated by the patients. The hospital cares for about 250 patients.

The urgent need of men to complete the train complement is strongly felt. One hundred men are needed in the field hospital section and 300 in the ambulance section. Yet, withal, our camp is unequaled in the division.

Great interest is evinced by officers and men in the first-aid dugouts to be built in connection with the trench system now being constructed by the division engineer.

The officers of the mounted organization of the sanitary train ride into the country each Wednesday afternoon studying roads, topography, mapping, etc. Problems will be taken up in November.

The Red Cross Association is spending several thousand dollars in clearing up the area about the camp. Surgeon Williams of the P. H. S. directs under the persuasion of Colonel Duncan. The Chamber of Commerce of the city of Macon appropriated $4,000 to help clean up the city.

The base hospital, Major R. W. Bliss, M. C., U. S. Army, commanding, will soon be ready to open, with 500 beds.

BASE HOSPITAL NOTES

The base hospital at Camp Wheeler is still under construction; no buildings are as yet completed. Our staff is all here and officers and men are having daily instruction.

At present all cases are sent to the field hospital. There are fifteen wards, each having on an average of twenty-five beds. It has been said that this is the largest field hospital in the history of the United States Army. This condition is accounted for by the fact that the base hospital is doing all its work there and at present several members of the base hospital staff are connected with the field hospital.

Lieutenant Horne was operated on for appendicitis by Major Cole about two weeks ago and is now sitting up and doing finely.

Lieutenants Upchurch and Miller, genito-urinary men from the base hospital, are doing the genito-urinary work at field hospital for the entire camp. They say they have not much time to gossip.

The officers quarters at the base hospital are practically completed and will be occupied the early part of this week.

Camp McClellan, Anniston, Ala.

The medical history of Camp McClellan dates from Aug. 18, 1917, when the First Virginia Field Hospital, in command of Major J. C. Bowman, arrived at camp. Being the first troops of the Twenty-Ninth Division to arrive in camp, the camp hospital was established by that organization, and it successfully cared for all the sick of the division until September 28, when the base hospital opened its doors.

PERSONNEL

The following assignments for the division have been made: Lieut.-Col. C. R. Snyder, M. C., U. S. Army, division surgeon; Major Junius F. Lynch, M. C., Va. N. G., former chief surgeon of Virginia National Guard, assistant division surgeon; Major J. H. Ulrich, M. C., Md. N. G., Baltimore, division sanitary inspector; Major James S. Fox, M. C., U. S. Army, commanding officer, base hospital; Major Valentine Ruch, M. C., N. G. N. J., former assistant chief surgeon, New Jersey National Guard, director, ambulance companies; Major L. H. Reichelderfer, M. C., D. C. N. G., former chief surgeon, District of Columbia National Guard, director, field hospitals.

The sanitary train of this division has been designated as the 104th sanitary train.

EXEMPTION OF MEDICAL STUDENTS AND INTERNS

Advice to Medical Students

Paragraph 1, Section Z of compiled rulings of Provost Marshal-General Number 11, dated Sept. 4, 1917, reads as follows:

> Hospital interns who are graduates of well recognized medical schools or medical students in their fourth, third or second year in any well recognized medical school, who have *not* been called by a local board for physical examination may enlist in the Enlisted Reserve Corps provided for by Section 55 of the National Defense Act under regulations to be issued by the Surgeon-General and if they are thereafter called by a local board, they may be discharged on proper claim presented on the ground that they are in the military service of the United States.

MEDICAL STUDENTS AND INTERNS NOT YET DRAFTED

In accordance with the above, the Surgeon-General has provided special regulations applicable to hospital interns and medical students. These may be summarized as follows:

"(*a*) Medical students and interns who have *not* been drafted may enlist in the Medical Enlisted Reserve Corps and thus be released from subsequent draft.

"(*b*) Interns who have served one year or more will not be enlisted in the Medical Enlisted Reserve Corps.

"(*c*) Any intern who is enlisted in the Medical Enlisted Reserve Corps may be called into service if needed at the end of one year of internship.

"(*d*) A medical student enlisted in the Medical Enlisted Reserve Corps may be called into active service under his enlistment if his services are needed or on failing to pass one class to another or on failing to graduate.

"(*e*) An internship of more than one year will not be recognized.

"(*f*) Hospitals, sanitariums and other institutions running for private gain will not be recognized in the consideration of interns.

"(*g*) The dean of the medical faculty must report twice a year on the status and progress of students in his school enlisted in the Medical Enlisted Reserve Corps."

Medical students and interns who have been accepted for the draft have already been given the opportunity of taking advantage of these special regulations and with these the advice offered at present has nothing to do. The question now under consideration is, What should medical students (who have *not* been called by a local board) and interns (who have not served one year or more) do in regard to enlisting in the Medical Enlisted Reserve Corps? This procedure is opened to them and we strongly advise that every medical student in a well recognized medical school and every intern who is a graduate of a well recognized medical school and who has served less than one year as an intern, should make application to the Surgeon-General for enlistment in the Medical Enlisted Reserve Corps.

ANNOUNCEMENT OF STAFF OFFICERS

National Guard Division

The following is a list of the medical staff officers in the various National Guard divisions:

26th Division.—Lieut-Col. James L. Bevans, surgeon; Major John G. Towne, assistant surgeon.

27th Division.—Camp Wadsworth, Spartanburg, S. C.: Lieut.-Col. Edward R. Maloney, surgeon; Lieut.-Col. Walter C. Montgomery, sanitary inspector; Major Lefferts Hutton, assistant surgeon.

28th Division.—Camp Hancock, Wheless, Ga.: Lieut.-Col. William J. Crookston, surgeon; Major C. A. Dillinger, assistant surgeon; Major William E. Kellar, sanitary inspector.

29th Division.—Camp McClellan, Anniston, Ala.: Lieut.-Col. Craig R. Snyder, surgeon; Major Junius F. Lynch, assistant surgeon; Major J. H. Ullrich, sanitary inspector.

30th Division.—Camp Sevier, Greenville, S. C.: Lieut.-Col. Arthur M. Whaley, surgeon; Major Alexander M. Brails, assistant surgeon; Major Naniwell, sanitary inspector.

31st Division.—Camp Wheeler, Macon, Ga.: Lieut.-Col. Louis C. Duncan, surgeon; Major William A. Padgett, assistant surgeon; Major Raymond C. Turck, sanitary inspector.

32d Division.—Camp MacArthur, Waco, Texas: Lieut.-Col. Perry L. Boyer, surgeon; Capt. Randall N. Cooley, assistant surgeon; Major Gilbert E. Seaman, sanitary inspector.

33d Division.—Camp Logan, Houston, Texas: Lieut.-Col. Levy M. Hathaway, surgeon; Major Gustavus M. Blech, assistant surgeon.

34th Division.—Camp Cody, Deming, N. M.: Lieut.-Col. Jacob L. Coffin, surgeon; Capt. L. B. Sturdevant, assistant surgeon; Major James E. Merrill, sanitary inspector.

35th Division.—Camp Doniphan, Fort Sill, Okla.: Lieut.-Col. William Davidson, surgeon.

36th Division.—Camp Bowie, Fort Worth, Texas: Lieut.-Col. Raymond F. Metcalfe, surgeon; Major John J. O'Reilly, assistant surgeon; Major Floyd J. Boland, sanitary inspector.

37th Division.—Camp Sheridan, Montgomery, Ala.: Lieut.-Col. Joseph A. Hall, surgeon; Major John C. Darby, assistant surgeon; Major Charles A. Neal, sanitary inspector.

38th Division.—Camp Shelby, Hattiesburg, Miss.: Lieut.-Col. Robert M. Blanchard, surgeon; Capt. A. C. L. Percefull, assistant surgeon; L. D. Carter, sanitary inspector.

39th Division.—Camp Beauregard, Alexandria, La.: Lieut.-Col. William N. Sinart, surgeon; Major John W. D. Dicks, assistant surgeon; Lieut.-Col. W. S. Schauffler, sanitary inspector.

40th Division.—Camp Kearny, San Diego, Calif.: Lieut.-Col. Alexander Murray, surgeon; Major William A. Jelley, assistant surgeon; Major Charles W. Decker, sanitary inspector.

41st Division.—Camp Fremont, Charlotte, N. C.: Lieut.-Col. Orville G. Brown, surgeon; Major F. M. Carroll, assistant surgeon.

National Army Divisions

The following are staff officers of the National Army divisions:

76th Division.—Camp Devens, Ayer, Mass.: Lieut.-Col. Llewelyn P. Williamson, surgeon; Major Joseph L. Siner, assistant surgeon.

77th Division.—Camp Upton, Yaphank, L. I.: Lieut.-Col. Charles R. Reynolds, surgeon; Major Alvin Schoenleber, assistant surgeon.

78th Division.—Camp Dix, Wrightstown, N. J.: Lieut.-Col. George M. Ekwurzel, surgeon; Lieut.-Col. John W. Hanner, assistant surgeon.

79th Division.—Camp Meade, Admiral, Md.: Lieut.-Col. Philip W. Huntington, surgeon; Major Guy L. Qualls, assistant surgeon.

80th Division.—Camp Lee, Petersburg, Va.: Lieut.-Col. Charles E. Marrow, surgeon; Major Henry P. Carter, assistant surgeon.

81st Division.—Camp Jackson, Columbia, S. C.: Lieut.-Col. Kent Nelson, surgeon; Major Thomas J. Leary, assistant surgeon.

82d Division.—Camp Gordon, Atlanta, Ga.: Lieut.-Col. Conrad E. Koerper, surgeon; Major William T. Cade, assistant surgeon.

83d Division.—Camp Sherman, Chillicothe, Ohio: Lieut.-Col. Wallace DeWitt, surgeon; Lieut.-Col. Samuel J. Morris, assistant surgeon.

84th Division.—Camp Taylor, Dumesnil, Ky.: Lieut.-Col. John H. Allen, surgeon; Major Luther R. Poust, assistant surgeon.

85th Division.—Camp Custer, Battle Creek, Mich.: Lieut.-Col. Cosam J. Bartlett, surgeon; Lieut.-Col. William A. Powell, assistant surgeon.

86th Division.—Camp Grant, Rockford, Ill.: Lieut.-Col. James M. Phalen, surgeon; Lieut.-Col. Howard H. Bailey, assistant surgeon.

87th Division.—Camp Pike, Little Rock, Ark.: Lieut.-Col. Robert M. Thornburgh, surgeon; Major Charles E. Freeman, assistant surgeon.

88th Division.—Camp Dodge, Des Moines, Iowa: Lieut.-Col. Jay R. Shook, surgeon; Major Clarence E. Fronk, assistant surgeon.

89th Division.—Camp Funston, Fort Riley, Kan.: Lieut.-Col. John L. Shepard, surgeon; Lieut.-Col. Frank W. Weed, assistant surgeon.

90th Division.—Camp Travis, San Antonio, Texas: Lieut.-Col. Paul S. Halloran, surgeon; Lieut.-Col. Robert H. Pierson, assistant surgeon.

91st Division.—Camp Lewis, American Lake, Wash.: Lieut.-Col. Peter C. Field, surgeon; Lieut.-Col. Lloyd L. Smith, assistant surgeon.

PROTECTION AGAINST VENEREAL DISEASES

On September 29, Senator Weeks reported a bill from the Committee on Military Affairs for the protection of military and naval forces, the aim being to guard these forces from physical and moral injuries of commercialized prostitution. It was read the first time by its title and the second time at length, as follows:

> *Be it enacted*, etc., That it shall be unlawful to keep or assist in keeping a place of prostitution to which any person known to be a member of the military or naval forces of the United States is admitted or to admit any such member to such place, or to knowingly rent or in any manner allow the use of any place for acts of prostitution with any member of such military or naval forces. No person shall solicit or seek to induce any person known to be a member of such military or naval forces to enter any place of prostitution or to consort or cohabit with any prostitute. Knowledge that a person is a member of the military or naval forces of the United States may be prima facie established by proof showing that the accused had knowledge that at the time or recently before the commission of the offense the person alleged to be a member of such military or naval forces was wearing the uniform of such military or naval forces. Whoever shall violate any of the provisions of this section shall be guilty of a misdemeanor and shall be punished by a fine of not more than $1,000 or imprisonment not more than one year, or by both such fine and imprisonment.
>
> Sec. 2. That it shall be unlawful for any person who has been convicted of disorderly conduct, delinquency, soliciting for prostitution, or any other sexual offense, without having first obtained permission from the proper military authorities, to loiter in or around a military camp, fort, navy yard, or place of training or mobilization. Any such person present in or around such camp, fort, navy yard, or place of training or mobilization, without authorization or military permission, may be ordered to depart by the civil or military authorities having jurisdiction therein. Any person failing to depart when so requested shall be guilty of disorderly conduct and shall be punished by a fine of not more than $100 or imprisonment of not more than 60 days, or by both such fine and imprisonment.

The bill was considered as in committee of the whole, reported to the Senate, one amendment ordered to be engrossed for the third reading, read the third time, and passed by the Senate.

INSTRUCTORS OF MEDICAL OFFICERS' TRAINING CAMP CONFER

On Oct. 8, 1917, instructors in the Medical Officers' Training Camps, including Col. Henry Page, Fort Oglethorpe, Ga.; Lieut.-Col. Percy M. Ashburn, Fort Benjamin Harrison, Ind.; Lieut.-Col. William N. Bispham, Fort Riley, Kan., and Major Ernest G. Bingham, Fort Des Moines, Iowa, met at Fort Benjamin Harrison in connection with the meeting of the American Association of Military Surgeons for a conference relative to the standardization of the course of instruction in the Medical Officers' Training Camps.

TAKING CARE OF SOLDIERS' FAMILIES

The *Survey* for September 29 reviews legislation enacted in various states providing allowances for the dependents of soldiers and sailors during the war. Connecticut, Maine, Massachusetts, Michigan, New Hampshire, Vermont and Wisconsin have enacted such legislation, and Colorado, Iowa, Kansas, Minnesota, New Jersey, New York, North Carolina, Oklahoma, Pennsylvania and Rhode Island have taken some sort of state-wide action for the same purpose. The legislation enacted in the states named is compared with the proposed Alexander-Simmons bill now pending in Congress, and points of incompatibility with the proposed national law are pointed out. In some of these states, the schedule of allowances approaches nearly that of the proposed national law, but in others, it is much less. In some of the states, these local laws will be rendered inoperative after the national law is passed. Other states which have not enacted laws providing for the care of dependents have made provisions for increased appropriations to existing institutions for the care of soldiers and sailors, as in the case of Colorado, which made an additional appropriation in 1917 for the Soldiers' and Sailors' Home. In Oklahoma, the State Department of Charities and Corrections has notified the National Defense Committee that the state will, through its hospitals, care for soldiers who may become mentally unbalanced, and is preparing to establish an institution for the care of veterans of the Civil and Spanish-American wars, as well as for those who serve in the present European war and their widows. It will thus be seen that a proper general interest is being taken by the states in the care of those who might otherwise suffer privation from the war.

NEW MEDICAL SERVICE BUREAU FOR RED CROSS

As announced by the Red Cross War Council, the growth of the work of the Red Cross Commissions in European countries during the past two months has made necessary the establishment of a Bureau of Medical Service of Foreign Commissions, to give prompt and expert attention to requests for medical and surgical supplies. This bureau will aid the commissions now at work in France, Russia, Roumania, Italy and Serbia. Requests for additional physicians and nurses, particularly in France and Roumania, for service with these commissions will also be handled by the new bureau. The physicians on this bureau are Drs. R. M. Pearce, Philadelphia, professor of research medicine, University of Pennsylvania, who will be the director; W. C. Bailey, Boston, associate director; Ralph Pemberton, Philadelphia, assistant, and John Gilbert, Philadelphia, secretary. The bureau is furnishing bacteriologists, chemists, surgeons and others for the Red Cross establishments in Paris. Drugs and medical supplies to the amount of more than $500,000 have been shipped to Russia, and three detachments of pediatrists have been recruited for service with the new children's bureau of the Red Cross in France.

WOMEN'S HOSPITAL UNIT ACCEPTED

The mobile hospital unit which the New York Infirmary for Women and Children has prepared has been accepted by the French government, through the High French Commissioner Tardieu. The unit is composed of a hospital with 100 beds and small flying auxiliary units. Its purpose primarily is to work among French women and children who have suffered from a lack of medical attendance, but it will also accept calls for the care of wounded soldiers. Dr. Caroline S. Finley is director of the unit, and expects to leave for France early in October to make arrangements for the reception of the unit. Preparations here are in charge of Dr. Anna I. Von Sholly and an executive committee, composed of Drs. Mary Lee Edward and Alice Gregory. The expedition is backed by the National Woman Suffrage Association.

AMERICAN ASSOCIATION OF MILITARY SURGEONS

Meeting at Fort Benjamin Harrison

The 1917 meeting of the Association of Military Surgeons began Sunday afternoon, October 7, at Fort Benjamin Harrison. With the onset of the war, a revival of interest in the association has occurred and it now numbers 4,000 members and has a substantial balance in its treasury. In addition to the men attending the meeting of the association, there were among the audience the 1,200 physicians who are taking the training course at Fort Benjamin Harrison and such enlisted men as were not engaged elsewhere.

A VISIT TO THE POST

On Sunday afternoon, the guests were invited to inspect the fort. There were included Captain Lung, medical director, U. S. Navy; Col. Charles Dircle and Major Edward Rist of the French Medical Corps; Col. T. H. Goodwin and Capt. J. Gilmour, R. A. M. C.; Cols. W. A. J. Shockley, E. L. Munson, W. N. Bispham and Henry Page, M. C., U. S. Army; Surg.-Gen. Rupert Blue and Asst. Surg.-Gen. W. C. Rucker, U. S. P. H. S., and Majors V. C. Vaughan and Joseph C. Bloodgood, M. R. C., U. S. Army. The first point visited was the sewage destruction pits designed by Col. Percy M. Ashburn, commandant, M. O. T. C., Fort Benjamin Harrison. Pits 6 feet deep are dug and the refuse poured in from iron cans, then covered with oil and allowed to digest itself.

The inspection of the field ambulances brought forth the interesting comment from the British officers that all of the British ambulances were now heated, utilizing the exhaust from the engine. None of the American ambulances were constructed with this provision.

EVENING SESSION

In the evening, the guests were assembled at the open-air speaking stand, which was surrounded with huge bonfires. Colonel Ashburn introduced Colonel Goodwin and Major Rist, who addressed the audience, felicitating the medical officers on the fact that France, England and America were now united as brothers in a common cause. A vaudeville program was provided by the medical officers in the training camp and the enlisted men, especially noteworthy being the singing of Paul U. Davies, professor of music in the Metropolitan School of Music, now an officer in the Ambulance Corps, and recitations by Capt. Daniel Hoyt, Philadelphia, of Company No. 2.

MONDAY MORNING

The Monday morning session was opened with the address of the president, Surg.-Gen. Rupert Blue, who called attention to the excellent status of the association and the great things promised for the future. Major Eduard Rist spoke on "Tuberculosis in the French Army." He said that the figures as to the prevalence of this disease have been greatly exaggerated. Out of 1,000 soldiers sent back to base hospitals with the diagnosis of pulmonary tuberculosis, all except 193 were returned to the front because the diagnosis could not be substantiated.

Reports were then received from the various officers of the association, and committees were appointed.

ADDRESS BY MAJOR VAUGHAN

The morning session was closed with a patriotic address by Major Victor C. Vaughan, which was most enthusiastically received. The men cheered until the speaker was forced to rise and bow his acknowledgment. Major Vaughan told of his experiences in the Spanish-American War when he entered as a reserve officer and made himself subject to court martial the first day by a kindly letter of protest to the colonel. He followed with a special address to men of German parentage or German sympathies in which he stated that he was convinced that all Germans were not in sympathy with the militaristic policy of the government. When in Berlin in 1907, Major Vaughan met Wassermann, the noted serologist. Late in the afternoon, Wassermann and Major Vaughan, leaving the Institute for Infectious Diseases, walked toward the city. They passed a barracks in which 50,000 soldiers were quartered on Berlin and at that time a hope was expressed that some day the flag of a republican Germany would fly over the buildings devoted, not to militarism, but to some scientific or peaceful purpose. Major Vaughan eulogized the student officers for volunteering without a draft and coming forth so nobly to do their duty. He told them that after the war they might not find their practices conserved, but they would more likely find that during their absence their competitors had fattened on their practice. They might be compelled to reestablish themselves in some side street, while their competitors held forth on the avenue, but they would be proud in their realization that they had served their country, whereas the competitor would find himself much abashed when his son asked him what he had done in the great war.

AFTERNOON SESSION

Most of the visitors took lunch at the mess of the student officers. The afternoon session opened with an address by Surgeon-General Braisted, M. C., U. S. Navy. General Braisted said that the Navy has obtained practically all the medical men needed for its service. Twenty-seven naval base hospitals have been constituted and five are already abroad on active duty. Following the address of Surgeon-General Braisted was a symposium by Col. Louis A. LaGarde, M. C., U. S. Army (retired); P. A. Surg. H. B. Eaton, U. S. Navy, whose paper was read by Fleet Surgeon McCulloch and Assistant Surgeon-General Rucker of the U. S. P. H. S., on "The Way in Which the Medical Military Service of the Government May Best Cooperate in Time of War." P. A. Surgeon Eaton was disappointed that the draft should have concerned only the Army without realization of the needs of the Navy, and stated that a true democracy would have drafted equally for the Navy as for the Army. Dr. Rucker expressed the hope that some day we might have a U. S. Medical Department in which all of the service could be united in one department working together under a common head. Major Joseph C. Bloodgood addressed the officers on various aspects of the surgery of the war and the questions for the civilian physician called to army life. Colonel Goodwin spoke on practical medical military lessons of the war, bringing up particularly questions of transportation and evacuation of the wounded.

PARADE AND REVIEW

The afternoon was closed with a parade and review of the medical officers' training camp. Some 5,000 men passed in review before the visitors. Just previous to the parade, Surgeon-General Gorgas arrived from Washington in time to see the brilliant strides made by the medical officers and the enlisted men of the medical department in their new duties.

THE BARBECUE

At 5:30 a barbecue supper, which had been prepared under the direction of Capt. Charles Parkes, M. R. C., Chicago, mess sergeant of Company No. 1, attracted the immediate attention of visitors, student officers and a host of guests.

On the platform at Fort Benjamin Harrison. From left to right: W. Colby Rucker, Asst. Surgeon-General, U. S. P. H. S.; Col. Edward L. Munson, M. C., U. S. A.; Surgeon-General Rupert Blue, U. S. P. H. S.; Capt. J. Gilmore, R. A. M. C.; Col. Charles Dircle, French Army Medical Corps; Major Eduard Rist, French Army M. C.; Col. T. C. Goodwin, R. A. M. C.; Capt. George A. Lung, Medical Director, U. S. N., and Col. Henry Page, commandant, M. O. T. C., Fort Oglethorpe, Ga.

THE NIGHT SESSION

The chilly night air and the fact that the motion pictures to accompany the address of Col. Charles Dirkel on "Medical Service on the Western Front" were not adapted to the motion picture machine caused the assembly to seek the neighborhood of the numerous bonfires. In the interim until new pictures could be brought, Surgeon-General Gorgas made a brief address and the choruses of the various companies vied in singing songs of the training camp. A parade-symbolizing the changes in the medical officer from his first arrival in camp until the completion of his course of instruction was one of the features of the evening.

NOTES

A sensation was created when Major McCormick's dog leaped into the sewage disposal pit, evidently believing it was the River Marne. He came out covered with ignominy and other things, and leaped into the major's car. The occupants of the car gave the dog complete possession, until he departed, and he could hardly find a dog on the grounds willing to associate with him although every company has at least two of indefinite ancestry. Later on he succeeded in removing most of the effluvia in an attempt to rout out a recalcitrant woodchuck; the remainder was washed off by a forced bath in Fall Creek. The officers of the Public Health Service were inclined to quarantine him, but relented following the disinfection and cleansing mentioned.

Some 300 civilian visitors took part in the barbecue. This gave opportunity to student officers to call each other major, and a few even became colonels pro tem.

The field ambulance at Fort Benjamin Harrison is equally divided among motor and army mule transportation. The American army mule was a subject of the greatest admiration to the foreign visitors, as were also the cavalry horses available at Fort Benjamin Harrison. Colonel Goodwin expressed sadness, as did many of the other American officers, at the gradual replacing of the "animals" by the less personal motor.

Colonel Dircle bears the scars of ninety-six shrapnel wounds.

At the barbecue supper four whole beeves, eight sheep, four pigs, 500 pumpkin pies, 4,000 doughnuts, ten barrels of sweet potatoes and six barrels of apples were eaten. The trimmings included thirty-five cases of celery and 100 pounds of salted peanuts.

During the parade and review Colonels Page, Bispham, Bingham and other instructors from the rival training camps stood around, watched the review and gnashed their teeth.

Exchange of Medical Officers Between France and Germany

The Germans accepted in 1916 the proposal to exchange the medical prisoners of war, and about three fourths of the French medical officers kept captive in Germany had been returned by October, but then no more were allowed to leave Germany. In April, 1917, the German government took up the matter again, and sent a list of their medical captives which they were willing to exchange. The French government checked up the list and designated the sixteen physicians and 759 other members of the sanitary service who had been designated in the agreement dated July, 1916, and demanded that these should be repatriated first of all. Germany accepted this, and the party recently arrived at Lyons. It has been agreed that the other medical officers and sanitary force are to be repatriated now in and with the least possible delay.

New Units to Camp

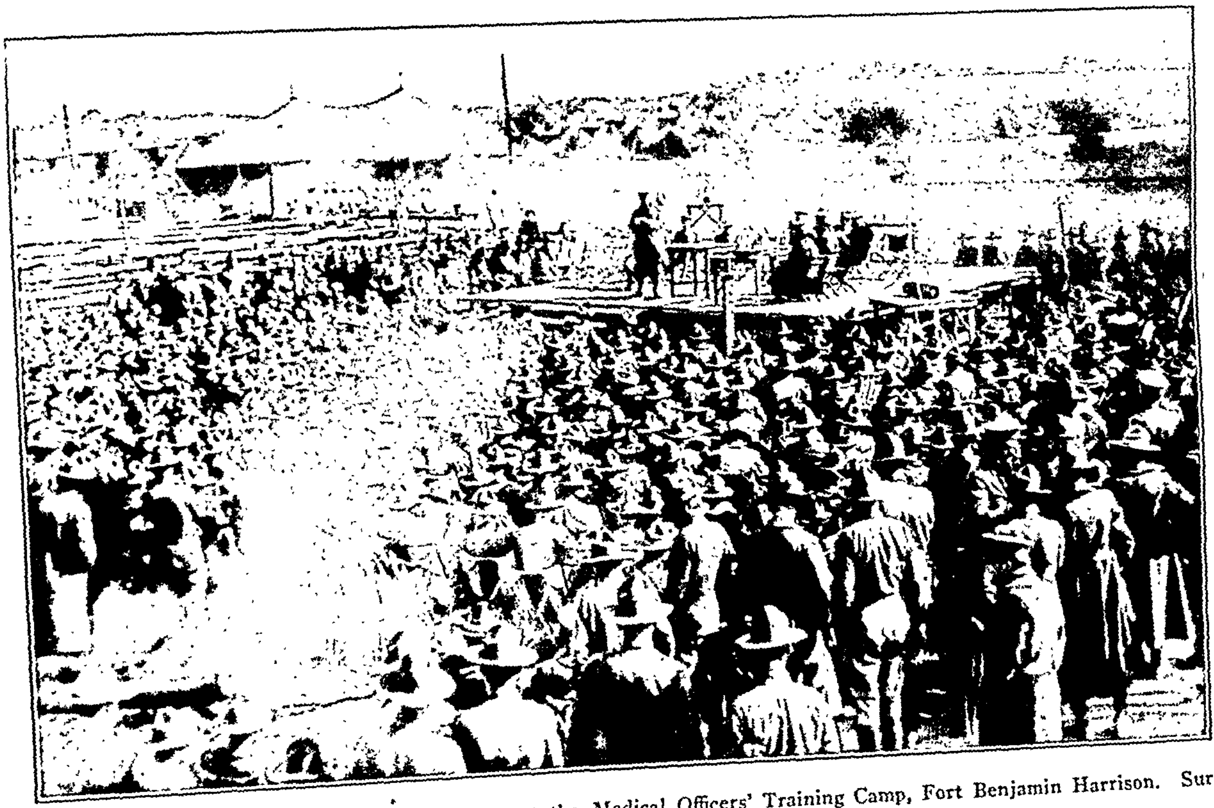
Two new units comprising Red Cross Ambulance Companies No. 4, Cleveland, and No. 3, Minneapolis, have reached the United States Ambulance Service Training Camp, Allentown, and a headquarters unit has been established at the camp by Director Col. Elbert E. Persons, under command of Col. Rossner E. Graham, M. R. C., New Orleans.

Court Martial

Asst. Surg. Thomas A. Fortescue, U. S. Army, is said to have been tried by general court martial at the Navy Yard, Norfolk, Va., on a charge of culpable negligence and inefficiency in the performance of duty, and to have been sentenced to lose three numbers. The Secretary of the Navy has approved the proceedings.

Bushnell's Retirement

Col. George E. Bushnell, M. C., U. S. Army, was transferred to the retired list, September 4, on attaining the age of 60. Colonel Bushnell entered the Medical Corps in February, 1881. He has given especial attention to the study of tuberculosis, and for many years he has been in command of the general hospital devoted to the treatment of tuberculosis at Fort Bayard, New Mexico.



First session of the Association of Military Surgeons at the Medical Officers' Training Camp, Fort Benjamin Harrison. Surgeon-General Rupert Blue, U. S. P. H. S., president of the association, delivering the opening address.

Personal

Lieut.-Col. Robert B. Grubbs, M. C., U. S. Army, was retired from active service, September 21, on account of disability incident to the service.——Surg-Gen. Presley M. Rixey, U. S. Navy, retired, has been recalled to active duty, and is now making an inspection tour of the Naval Coasts and Hospitals in the United States.——Capt. John S. Fulton, Baltimore, has been added to the board to prepare material for a medical and surgical history of the war.——Medical Inspector Frank L. Pleadwell, U. S. Navy, has returned after service in England and along the western front since May, 1916. During this time he visited sixty-four hospitals, five ambulance trains, six training and convalescent camps, twenty naval vessels, including eleven hospital ships, and four medical service schools, the High Seas fleet, the British trenches in France and the Italian front on the Isonzo.——Capt. James W. Inches, M. R. C., U. S. Army, health officer of Detroit, who sailed for France, September 5, as a member of a Red Cross Mission to investigate the needs of soldiers at the front, arrived, September 25.

NEWS OF THE TRAINING CAMPS

At Fort Oglethorpe

The week of October 1, at Camp Greenleaf has, from a seasonal point of view, been one of the most delightful since the beginning of camp. Early autumn weather of the choicest sort prevailing, with its accompanying harvest moon, has made the nights poetic dreams. One of the most beautiful nights was taken advantage of by the commandant who gave a lecture out in the open, there being no other illumination than the moon. The lecturer was at his best, the scenic effect beautiful beyond description, and the impression made on the men a lasting one.

MESS AT FORT OGLETHORPE

A distinct departure from the mess as conducted at the other Medical Officers' Training Camps is that initiated by Col. Henry Page at Camp Greenleaf, Fort Oglethorpe, Ga. The medical officers are marched into the mess hall at "attention" and are seated in order. After mess the men are again called to attention, and empty plates are shown. The reduction in wastage approximated 60 per cent. when an average ration was served to each man, and empty plates were shown after mess. This might be regarded as a practical demonstration in food conservation.

HIKES

Practice hikes have been in order this week and five or six marches have been made. On Friday the entire student body hiked to Jays Mill, the spot where the battle of Chickamauga started, and witnessed the erection of a complete field hospital. Lieutenant-Colonel Carswell, the director of field hospitals, was in charge and the demonstration he gave was a most interesting one.

NEW MEN

There has been an influx of new men into camp this week and at present there are nearly 1,400 medical officers here. The ages of the men are younger than at the first camp.

NEW INSTRUCTORS

Lieut.-Col. Roger Brooke, the senior instructor, has increased his corps of instructors and now he has courses so arranged that the new men do not have to enter in the midst of the course without knowing what has gone on before. The brunt of the teaching has fallen on the shoulders of Colonel Brooke and his ability as an instructor is unsurpassed. The majority of the men acclaim him as superior to their old "profs." which within itself is somewhat of a miracle for it is a well known fact that medical men seldom acknowledge that any one can compare with the instructors in their old alma mater.

RETREAT

Each evening at 5:15 o'clock retreat is held at Camp Greenleaf and the spectacle of so many physicians, many of whom enjoy national reputations, in formation draws countless throngs from Chattanooga and vicinity to witness it. It is most imposing and the lines, as they pass the reviewing officer, are well nigh perfect. A line officer who was present a few evenings ago paid them the very high compliment of saying "they drill like regulars."

PERSONALS

A negro minstrel show, composed entirely of members of this camp, was given at the amphitheater a few evenings ago and was greatly enjoyed. There were many wives of the officers present in the audience. Lieutenant Lemkowitz brought down the entire house when he said that Chattanooga was not a city but a saluting station for Camp Greenleaf.

MARRIAGE OF MAJOR KIRK

Major Norman C. Kirk, M. C., one of our youngest and most popular instructors, put one over on the entire camp last Friday evening by slipping over to the post chapel and marrying Miss Duryea of New York. The proper way to write up a wedding is to mention how the bride was dressed, whether or not she carried a bouquet, and say a word or two about the wedding march, and devote the rest of the space to those present, but owing to the modesty of the guilty parties no one knows about these highly important facts except the parson and he will not tell us a "darn" thing. If good wishes have anything to do with it they will have a long, happy and prosperous voyage on the sea of matrimony.

Major A. C. Abbott gave a most instructive lecture on the fly last Thursday evening. It was illustrated by moving pictures which told in story the dangers of the fly.

Major Owen has been joined by Mrs. Owen and family, who are living on Missionary Ridge.

Capt. Newdigate M. Owensby, M. R. C., has returned from a short visit to Baltimore.

THE NATIONAL GAME

Last Sunday a baseball gave was played on Dyer Field between student companies number 8 and 3. Three company was the victor and is now thinking of issuing a challenge to the winners of the world's series.

To Camp Travis, Fort Sam Houston, Texas, from Fort Benjamin Harrison, Ninetieth Division, for duty as tuberculosis specialist and assistant to the Army Medical Staff, Lieut. Herman H. Bassler, Oshkosh.

To Fort Benjamin Harrison, for instruction in tuberculosis examination, Lieut. Adelard E. Gendron, River Falls.

To Fort Oglethorpe, for instruction, Lieuts. Cornelius J. Corcoran, Harry B. Podlasky, Milwaukee; Charles A. Dawson, River Falls; Orlando P. Schoofs, Wauwatosa.

WYOMING

To Fort Ontario, N. Y., duty with Field Hospital and Ambulance Companies Nos. 28 and 30, Lieut. W. S. Bennett, Cody.

Medical News

(Physicians will confer a favor by sending for this department items of news of more or less general interest; such as relate to society activities, new hospitals, education, public health, etc.)

CALIFORNIA

Personal.—Dr. Sherman T. White, Redding, county physician of Shasta County, sustained a fracture of the patella when his automobile collided with another machine, September 17.——Drs. Clayton G. Stadfield and Byron Stuckey, assistant surgeons at the Receiving Hospital, Los Angeles, have resigned to enter military service, and have been succeeded by Drs. Elmer L. Biggs and John W. Crossan.——Dr. Karl L. Dieterle has been appointed surgeon at the Receiving Hospital, Los Angeles.

Medical Research Society Organized.—A clinical society to further medical and surgical research was organized in the San Francisco Hospital, September 26, and the following officers were elected: president, Dr. Robert A. Jones; vice president, Dr. H. J. Pruett; secretary, Dr. Maurice Heppner, and treasurer, Dr. Robert A. Powers.

Tuberculosis Society Moves.—The Los Angeles Society for the Study and Prevention of Tuberculosis has moved its office from Normal Hill Center to 538 Chamber of Commerce Building.

Faculty Members in Active Service.—Among the members of the faculty of the University of California Medical School who have been called into active service in the Medical Officers Reserve Corps are Dr. Herbert C. Moffitt, San Francisco, professor of medicine and dean of the medical school, who has been commissioned major, and stationed at the Army Hospital at San Antonio, Texas; Dr. Eugene S. Kilgore, who has been commissioned major, and is stationed at the Presidio in San Francisco; Dr. Alanson Weeks, instructor in surgery, commissioned major; Dr. Howard E. Ruggles, assistant clinical professor of roentgenology, and Dr. Jule B. Frankenheimer, instructor in medicine, commissioned captains; and Drs. Elbridge J. Best, Frank P. Brendel, Arthur C. Gibson, Charles L. Tranter and Daniel W. Sooy, commissioned first lieutenants.

COLORADO

Personal.—Dr. John L. Schwer, Pueblo, is ill with typhoid fever in St. Mary's Hospital.——Dr. William E. Stemen, Denver, has been appointed chief surgeon of the National Guard, Colorado Springs, succeeding Major William A. Jolly, Boulder, who has been appointed assistant to the chief surgeon, Camp Kearny, Linda Vista, Calif.

State Society Meeting.—The forty-seventh annual meeting of the Colorado State Medical Society was held in Colorado Springs, September 25 to 27, under the presidency of Dr. Alexander C. Magruder, Colorado Springs, and the following officers were elected: president, Dr. Edward Jackson, Denver; vice presidents, Drs. Peter O. Hanford, Colorado Springs; John H. Bush, Sterling; Byron B. Blotz, Rocky Ford, and Charles Trueblood, Monte Vista; secretary, Dr. Crum Epler, Pueblo (reelected for the third term); treasurer, Dr. William A. Sedwick, Denver; delegate to the American Medical Association, Dr. Lewis H. McKinnie, Colorado Springs, and alternate, Dr. Melville Black, Denver. Estes Park was decided on as the place of the next annual meeting. A resolution was adopted to give financial support, when needed, to the families of all members of the association in war service. One hundred and forty members of the society are at present in the Medical Corps or Medical Reserve Corps of the Army.

DISTRICT OF COLUMBIA

Building Commandeered for Medical Department.—The Premier apartment house, 1718 Eighteenth Street N.W., Washington, is reported to have been commandeered by the United States government for the use of the Medical Department of the Army.

Hospital to Move.—The Washington Eye, Ear, Nose and Throat Hospital will move into its new building at 2517 Pennsylvania Avenue, October 17. The new building is four stories in height, fireproof, and occupies a frontage of 56 feet. The completion of the hospital is largely due to the efforts and contribution of Dr. Oscar Wilkinson.

Medical Society Centennial.—The Medical Society of the District of Columbia will celebrate its one hundredth anniversary, October 17. Exercises will be held in the hall of the National Museum, and a banquet will be given at the Raleigh in the evening. The society, which was organized in 1817, with an initial membership of sixteen, has now more than 600 members.

ILLINOIS

Conference of Charities and Corrections.—The State Conference of Charities and Corrections will be held in Joliet, October 26 to 28.——The Charity Organization Confederation and the State Probation Officers' Association will meet on October 25, and the State Association of County Home superintendents, October 25 and 26, in the same city.

Personal.—Dr. Fred M. F. Meixner has been appointed medical director of the new Peoria Municipal Tuberculosis Sanatorium, and assumed his duties, October 1. The building under construction will be finished about March 1, and in the meantime patients will be cared for in the pavilions now open on the grounds.——Dr. Marguerite G. Squires, Carrollton, has been appointed county physician of Grundy County.——Dr. Hiram J. Smith, assistant superintendent of the Ann State Hospital, has been appointed superintendent of the Illinois Charitable Eye and Ear Infirmary, Chicago, succeeding Dr. James L. O'Connor.

Chicago

Glanders Case Found.—A case of glanders is said to be under treatment and in strict quarantine in St. Luke's Hospital. The disease is presumed to have had its source in the barns of an express company where five horses suffered from the disease.

Provident Hospital in Need.—An urgent appeal to raise $15,000 has been made by the trustees of the Provident Hospital, which was founded in 1896 for the care of colored sick and injured in Chicago. On account of shortage of funds the free dispensary of the institution has been forced to close its doors.

IOWA

Open-Air School in Sioux City.—The board of supervisors of Woodbury County have approved the establishment of an open-air school on the roof of the new court house, for the accommodation of tuberculous and anemic children.

Personal.—Dr. David W. Reed, Clearfield, suffered a fracture of a rib, September 20, as a result of the overturning of his [illegible] Major David S. Fairchild, Jr., M. C., Iowa N. [illegible] transferred to the military service of the United States, and has been assigned to duty with the Forty-Second Division.

County Clinics on Tuberculosis.—A. E. Kepford, state lecturer on tuberculosis and director of Red Cross work in Iowa, has planned tuberculosis clinics in every county of the state, to be held by the county medical society. The first clinic was held at Clarion, September 21. With these clinics it is expected to accomplish the stamping out of tuberculosis by early diagnosis, the arousing of the people to the perils of the disease, and the stirring up of interest among the medical profession.

Hospital Items.—The Cottage Hospital, Albia, has been discontinued on account of the difficulty in obtaining help. ——Dr. Carl E. Conn, Sioux City, has purchased the Dennison Hospital and Sanatorium at a price stated to have been $7,600.——The John MacDonald Hospital, Monticello, was formally opened to the public, September 6. The hospital is three stories in height, of brick and stone construction, and has the most complete and up-to-date equipment.——The new State Hospital for Epileptics, at Woodward, is completed and in active operation.

KANSAS

Typhoid.—Between fifty and sixty cases of typhoid fever were reported in and around El Dorado during the first two weeks of September. The county health officer urges the boiling of water, the abolition of flies, the covering of food, and the like.

Personal.—Dr. Samuel A. Matthews, professor of physiology and experimental pharmacology in the University of Kansas, Topeka and Lawrence, has accepted the similar chair in the University of Alabama, Mobile.——Dr. Stewart McKee has been appointed city physician of Leavenworth, succeeding Capt. Charles McKee, who is at Fort Riley in the military service.——Dr. Thomas A. O'Connor, Topeka, has been appointed county physician of Shawnee County, to fill the unexpired term of Dr. C. C. Lowe, called to the colors.——Dr. Matthew R. Mitchell, North Topeka, has given up his office and moved to Florida.

MARYLAND

Epidemic of Scarlet Fever.—An epidemic of scarlet fever is prevalent in Federalsburg. Several families are quarantined as a result of the outbreak, and the county health officers are using every precaution to stamp out the disease.

Child Welfare Unit for France.—The child welfare unit to be sent abroad by the American Red Cross, in charge of Dr. J. H. Mason Knox, will leave for France about October 13. Dr. James L. Gamble, assistant in pediatrics at the Harriet Lane Hospital for Children, a part of the Johns Hopkins Hospital, will accompay Dr. Knox.

Typhoid Fever Outbreak.—Typhoid fever has broken out at the Maryland School for Boys, an industrial institution at Loch Raven. At present there are thirteen cases under treatment. The state board of health is conducting an investigation to ascertain the cause of the outbreak and has provided antitoxin to inoculate all the school. The outbreak is thought to be due to a typhoid carrier.

Medical Men Assigned to Regiment.—The men who will form the Medical Corps attached to the 115th (Maryland's Own) Regiment, now stationed at Anniston, Ala., have been selected from the three old regiments and are under the command of Major Frederick H. Vinup. His staff is composed of Capt. William J. Coleman, former superintendent of the University Hospital, Baltimore; Lieuts. Dwight H. Mohr, Roscoe Hannigan, Daniel Woodruff, J. K. Richards and Daniel Hutton. Under their command will be an enlisted personnel of forty-eight men, thirty-three of whom will be selected from the Fifth Regiment and the rest from the First.

Health Department Report.—According to a report made by the health department for September, 147 babies under 2 years of age died in Baltimore from intestinal troubles. Ninety-three babies died in September last year. The increase is said to be due to atmospheric conditions rather than to outbreaks of diseases usually fatal to infants in summer and early autumn. Deaths in the city last month from all causes totaled 869, compared with 750 in 1916; 704 in 1915, and 771 in 1914. Diseases were fatal in the following number of cases: typhoid fever, 15; measles, 4; grip, 2; cancer, 54; tuberculosis, 104; apoplexy, 52; heart disease, 79; bronchitis, 7; pneumonia, 57; Bright's disease, 63; meningitis, 1. There were 1,242 births reported.

MISSOURI

Sanatorium To Be Closed.—Dr. William H. Coon, health director of Kansas City, proposes to close the Leeds Tuberculosis Hospital, concentrating the antituberculosis work in the General Hospital, with a downtown clinic to be established for this work.

Personal.—Major Charles E. Wilson, Kansas City, surgeon of the Second Missouri Field Artillery, and formerly fire department surgeon, was presented with a handsome wrist watch and a pair of field glasses, September 8. The gift came from 375 city firemen.——The Civil Service Board of Kansas City, August 29, waived the ruling requiring a civil service examination and residence in the city for three years, in the case of Dr. Elliott Washburn, the new manager for the hospital division of the board of health.——The Board of Health of St. Joseph, at its meeting, August 30, released Dr. John L. Cox as surgeon, and appointed Dr. V. R. Wilson his successor.

Honor to Fitzsimmons.—The first meeting of the Jackson County Medical Society after the summer vacation was held in Kansas City, September 18. A military program was given, at which Col. William N. Bispham, M. C., U. S. Army, Fort Riley, Texas; Lindsay S. Milne, director of the ambulance company at the same post, and Capt. W. M. McBride of Camp Funston spoke. Resolutions were adopted on the death of Lieut. William T. Fitzsimmons, Kansas City, the first American officer to be killed in France.——In the United States House of Representatives, Representative Borland of Missouri introduced a resolution ordering the War Department to promote the late Lieutenant Fitzsimmons to a captaincy.

NEW JERSEY

Antituberculosis Clinic Grows.—The clinic of the Middlesex County Anti-Tuberculosis League which is held weekly at the Perth Amboy Hospital and at the rooms of the board of health, New Brunswick, is gradually increasing. The freeholders have recently purchased 208 acres of land near Metuchen on which to erect a county tuberculosis sanatorium.

Personal.—Dr. Louis Shalet has resigned as superintendent of the Montefiore Home and County Sanatorium, Bedford Hills, and will practice in West New York.——Lieut.-Col. William G. Schauffler, Lakewood, chief surgeon of the New Jersey National Guard, has been appointed assistant surgeon at Camp Beauregard, Louisiana.——Dr. William S. Jones, Camden, has been appointed a member of the board of managers of the Glen Gardner Tuberculosis Sanatorium, succeeding Dr. William H. Kinsinger, Camden.

NEBRASKA

Hospital Changes Hands.—The Wesleyan Hospital at University Place, Lincoln, has been purchased by Dr. Elbert J. Latta and other physicians, who assumed charge of the institution, September 1.

Smallpox.—September 21, twenty-four persons in eight Omaha families were reported to be ill with smallpox.——An epidemic of smallpox in Rokeby has caused quarantine of the postoffice in that place.

University of Nebraska Hospital Opened.—The University of Nebraska Hospital, located on the Medical College Campus, Lincoln, was opened for the reception of patients, September 1. The building is four stories in height, and has accommodation for 120 patients.

Furnas County Physicians Meet.—At the meeting of the Furnas County Medical Society, held in Arapahoe, August 5, Dr. Lee W. Rork, Oxford, was elected president, succeeding Dr. Fordyce H. McCabe, and Dr. John K. Muldoon, Arapahoe, was elected secretary, succeeding Dr. James M. Willis, Arapahoe. Both these officers have entered the service of the country.

Personal.—Dr. Roy A. Dodge, Omaha, has been appointed division surgeon for the Missouri Pacific Railroad system. ——Dr. Ernest O. Weber, Waco, has been commissioned, by the governor as major, Medical Corps, Neb. N. G., and has been assigned to duty as medical inspector of the new National Reserve Regiment, succeeding Dr. Frank S. Nicholson, St. Paul, retired.

NEW YORK

Assistant Resident Physician Wanted.—A civil service examination for first assistant resident physician in the Iola Sanatorium for the Treatment of Tuberculosis, Monroe County, will be held in the near future; salary $1,200 a year and maintenance; applicants must be citizens of the United States, licensed physicians of New York state, graduates of an incorporated medical college, at least 21 years of age, and must have been for at least three years' residents of the state. It is desired to secure an appointee who has had experience in the institutional treatment of tuberculosis. Requests for application form should be made to the State Civil Service Commission, Albany, and applications must be filed prior to October 24.

New York City

New York Academy of Medicine.—The Wesley M. Carpenter lecture is to be delivered at the next meeting of the New York Academy of Medicine, October 18, by Dr. William H. Mayo of Rochester, Minn. His subject will be "The Rôle of the Spleen in the Production of a Number of Obscure Clinical Phenomena."

Flower Hospital to Become Base Hospital Unit.—At a meeting of the Flower Hospital War Relief and its affiliated societies, held on October 5, Dr. Royal S. Copeland, dean of the hospital, announced that application had been made to turn the Flower Hospital into a base hospital unit and that this application would soon be granted. It was voted to increase the appropriation for medical supplies from $10,000 o $25,000 and to double the personnel of the hospital.

Red Cross Rally.—The first great Red Cross parade ever held in this country and the largest body of war nurses ever gathered together paraded Fifth Avenue on October 4. The fifty Red Cross chapters represented succeeded in giving one of the most impressive demonstrations of the scope of America's war preparations that New York has witnessed. Among those leading the parade were Major-Gen. William C. Gorgas, Rear Admiral William C. Braisted and Henry P. Davison.

The Poets' Ambulances.—The American Poets' Committee which announced some time ago that it would send 50 ambulances for General Cadorna's army now announces that it proposes to send 100 ambulances. It has already purchased 28 ambulances by cable to be put into the field immediately and has funds for the purchase of 12 more. A unit of $2,000 purchases one ambulance and a number of individuals have contributed this sum. Ambulances purchased in this way bear the name of the donor, not as a matter of pride but as a reinforcement of Italian valor.

Urge Government Control of Narcotic Drugs.—As a result of the disclosure of the extent of criminal traffic in narcotic drugs in this city the Federal Grand Jury has passed unanimous resolutions asking United States Attorney Caffey to take the matter up with the federal government. These resolutions contain recommendations urging that chemists and internal revenue inspectors be assigned to every plant where the drugs are manufactured; that the product be shipped to government warehouses in zones to be established; that the government should control the price, the quantities shipped to wholesale druggists, jobbers, dealers, retailers and pharmacies, all of whom, and manufacturers as well, should be bonded and licensed, and that the government should control exports and imports. The resolutions request that an adequate bill be prepared for presentation to Congress that will prevent the continuance of conditions such as have been brought to light by the investigations of the internal revenue inspectors in this city.

Free Clinic for Speech Defects.—In view of the fact that many American soldiers are likely to return from the front with their powers of speech impaired either as the result of wounds or of shell shock, the various branches of medicine bearing on the treatment and correction of speech defects have been coordinated in a new institution which has been incorporated under the name of the New York Clinic for Speech Defects. This clinic will be opened at 143 East Thirty-Seventh Street sometime during the month of October, with Dr. Herbert L. Wheeler as president. Among those interested in the project are Dr. Abraham Jacobi, Thomas A. Edison, Drs. John E. MacKenty, Philip D. Kerrison, George M. Parker and James Sounett Greene, who will have charge of the clinic. In addition to treating the speech defects that result from war injuries, defects inherited or acquired will be treated and those having a foreign accent which they wish to overcome will be treated as though the accent were a speech defect. The institution will be supported by private philanthropy.

High Cost of Milk Problem.—Owing to the intimate relation between the cost of milk and child welfare the health department believes that this is a matter in which it should directly concern itself. Inquiries already made and still under way among the families of the poor show that the use of milk has been decidedly restricted because of the increased price. In some places the sales of milk for family use have decreased as much as 20 per cent. The health department attributes a notable increase in the number of deaths from diarrheal disease in children under 1 year of age to this practice. As a result of the facts brought out, Commissioner Emerson has written a letter to Mayor Mitchell suggesting that the city schools, baby health stations, settlement houses, hospitals, dispensaries and police stations be used as central points for the distribution and sale of milk, bread and perhaps other staple articles of food whose cost is excessively high because of the wastefulness of present methods of distribution. At the request of the health commissioner, the mayor has appointed a committee to elicit all the facts in relation to this matter and to make constructive suggestions.

OREGON

Sanatorium Opened.—The new sanatorium of Dr. Edward A. Pierce, Portland, known as Cedar Crest Farm, is now completed and opened for patients. The building is located near the city limits of Portland, overlooking the Willamette Valley, and is two stories in height, with extensive verandas on both floors.

Personal.—Dr. J. Hunter Wells has returned to Portland and assumed practice after twenty-two years spent in the missions and mines of Corea.——Dr. John H. McVay, Hood River, who sustained serious injuries to his spine a year ago, is reported to be seriously ill in the Hood River Hospital. ——Dr. Frank M. Brooks, Portland, has been appointed a member of the state board of health, succeeding Dr. Marius B. Marcellus, who has been called to the colors.——Dr. William H. Dale, Harrisburg, has been appointed a member of the State Medical Board, to succeed Dr. Harry E. Clay, Salem, who has entered the military service.——Dr. Alvin F. Sether, Roseburg, is ill with typhoid fever.

PENNSYLVANIA

Philadelphia

Reception of Dr. Prince.—The Medical Club of Philadelphia will give a reception in honor of Dr. Morton Prince of Boston, October 19, at the Bellevue-Stratford Hotel.

Social Diseases.—At the stated meeting of the College of Physicians and Surgeons, Col. Thomas H. Goodwin made a brief address; Col. Frederick F. Russell, M. C., U. S. Army, presented a paper on "Social Diseases in the Army"; Major William F. Snow, M. C., U. S. Army, a paper on "Social Diseases in the Army as Effected by the Soldier's Environment"; Mr. George W. Braden, a paper on "The Present Site of Social Diseases." Dr. William W. Keen presented to the college the retractor used in the operation on President Grover Cleveland in 1893.

Personals.—Major George E. deSchweinitz, Medical Reserve Corps, has been assigned to active duty at Philadelphia for the purpose of compiling a handbook on ophthalmology for the use of the Surgeon-General of the Army.——Dr. Santos Fernandez, president of the Cuban Academy of Science, and one of the most distinguished eye surgeons of Cuba, was the guest of honor at a luncheon given October 2 by Dr. William Campbell Posey of the Wills Eye Hospital.——Dr. J. Torrance Rugh has been commissioned captain, M. R. C., U. S. Army, and appointed by the Surgeon-General as an instructor in orthopedics at the southern camps.

SOUTH DAKOTA

New Officers.—The annual meeting of the Lake Preston Medical Society was held at Lake Preston, October 3, the president, Dr. E. H. Grove, Arlington, in the chair. Dr. Burtis T. Green, Brookings, was elected president; Dr. Lorenzo N. Grosvenor, Huron, vice president, and Dr. John C. Baker, Ramona, secretary-treasurer.

Work on Sanatorium Commenced.—The state board of charities and corrections, having failed to secure bids for the construction of the addition to Custer Tuberculosis Sanatorium, has undertaken the carrying on of the work itself, and expects to have the most important pavilion ready for use before winter sets in.

WYOMING

Medical Society Meeting.—The Northwest Medical Society held its quarterly meeting in Worland, recently, and elected the following officers: president, Dr. Will V. Gage, Worland; vice president, Dr. Chester E. Harris, Basin, and secretary-treasurer, Dr. W. B. Mauis Powell. The next meeting will be held in Lovell, December 2.

CANADA

Personals.—Prof. John C. McLennan, Ph.D., head of the department of physics, University of Toronto, and member of the Canadian Commission on Chemical Research, is among the first group to receive the honor of the new Order of the British Empire.——The name of Col. Herbert A. Bruce, Toronto, is prominently mentioned in connection with the nomination of federal candidates for parliamentary honors in the coming Dominion election. Dr. Bruce, who is still in France, may possibly contest the constituency of North Toronto in the Liberal-Conservative interest.

Winnipeg's Vital Statistics.—According to the report of the city assessor of Winnipeg for 1917, as set forth in the *Bulletin* of the health department, there has been a reduction in the population of over 17,000 as compared with 1916. The figures for 1917 are 182,848, and for 1916, 200,000. This decrease has been going on since 1914, and the enlistments for the war and the removal of the floating population are assigned as reasons. This had had an interesting effect on the vital statistics of the city. The births for 1917 were 2,842, as compared with 3,046 for 1916. Though this is a reduction in the actual number of births, there has been an increase in the number of births per thousand, which is accounted for by the fact that the number of mothers in the city has increased. Many families from which the soldier has gone to war have moved into the city from the surrounding country. The marriages in 1917 were 1,158, as compared with 1,482 in 1916. It is said that the marriage rate has undoubtedly decreased among those of marriageable age, but exact figures on this point are not available. It should be based on the number of single men and women of marriageable age. The substitution of families of young children in the place of adults would be expected to have had an unfavorable influence on the mortality rates, but it is noted that for the six months of 1917 the rate was 10.41, as against 11.13 for 1916. The number of deaths from disease of the respiratory system, diarrheal diseases in children under 2 years of age, tuberculosis of all forms and deaths from external causes all decreased. The mortality rate for the acute communicable diseases also shows a slight decrease. Deaths from cancer in persons over 40 show increases.

Hospital News.—An institution for the education and training of blind soldiers is to be established at Halifax, N. S. The organization work will be under the supervision of Sir Frederick Fraser, Halifax, who has been so successful in building up the Halifax School for the Blind.——The summer hotel at Qualicum, Vancouver Island, B. C., has been converted into a convalescent home for returned soldiers. The institution now holds 100 patients.——A few months ago a municipal hospital act was passed in the province of Alberta which provides that the province shall be divided into districts and that hospital boards shall be appointed to provide for the location and purchase of suitable hospital sites; the purchase, acquisition, or erection of suitable buildings, furnishings and equipment. Although the act does not compel a municipality to establish a hospital, every facility and inducement is offered for the establishment of such hospitals. The provisional government will see that money collected for this purpose shall be expended to the best advantage.——Approximately 1,500 patients admitted to the Toronto Military Base Hospital every year are afflicted with venereal diseases; and during the first three months of 1917, 12 per cent. of all patients in the public wards of the Toronto General Hospital gave a positive Wassermann reaction. Twenty-five per cent. of the male admissions to the Toronto Hospital for the Insane are cases of general paresis.——About 1,200 tuberculosis cases among returned soldiers have thus far passed through the hands of the Canadian Hospitals Commission, while over 800 are undergoing treatment.——An advisory committee on tuberculosis has been appointed to assist the Canadian Hospitals Commission. The members of that committee are Capt. John R. Byers, Ste. Agathe, Que.; Dr. Charles D. Parfitt, Gravenhurst, and Dr. Jabez H. Elliott, Toronto.

GENERAL

Prevention of Infant Mortality.—The eighth annual meeting of the American Association for the Study and Prevention of Infant Mortality will be held in Richmond, Va., October 15 to 17, under the presidency of Dr. William C. Woodward, Washington, D. C. The subjects to be discussed by the association will be, "Pediatrics; Obstetrics, Propaganda; Vital and Social Statistics; Rural Communities; Nursing and Social Work, Eugenics, and Public School Education for the Prevention of Infant Mortality.

Social Hygienists to Meet.—The annual meeting of the American Social Hygiene Association will be held at the Belvedere Hotel, Baltimore, October 19, for the election of officers and directors, and to consider further mergers with social hygiene societies and other agencies. A program of public meetings and conferences has been arranged jointly with the American Health Association for October 18, and on the morning of October 19, and in Baltimore with the Baltimore Medical Society and the Maryland Social Hygiene Society on the afternoon and evening of that day.

District Society Meeting.—The regular fall meeting of the Iowa and Illinois Central District Medical Association was held at the Rock Island Club, Rock Island, Ill., October 11. The scientific program included illustrated lectures on "The Diagnosis of Renal Tuberculosis," by Nathaniel G. Alcock, Iowa City, Iowa, and "Recent Studies in the Etiology and Treatment of Experimental and Human Poliomyelitis," by Dr. John W. Nuzum, Chicago, and a discussion of "Some Medico-Economic Questions," by Dr. David S. Fairchild, Clinton.

National Board in Session.—The third examination of the National Board of Medical Examiners is now being conducted in the Cook County Hospital. The session this year will cover an entire week, beginning Wednesday, October 10. About sixty-five candidates are being examined. The certificates of this board are now recognized by the licensing boards of Colorado, Delaware, Idaho, Iowa, Kentucky, Maryland, New Hampshire, North Carolina, North Dakota, Pennsylvania, Rhode Island and Vermont. Several other states are contemplating similar action.

Bequests and Donations.—The following bequests and donations have recently been announced:

Methodist Episcopal Hospital, Indianapolis, $75,000, by the will of Mrs. Emma Messick, Shelbyville.

College of Physicians and Surgeons in the City of New York, a donation of $50,000 for the necessary enlargement of the medical school equipment to care for women students, by George W. Brackenridge, San Antonio, Tex.

The Martinez Anti-Tuberculosis Fund, Dallas, Tex., for the treatment and assistance of indigent persons affected with tuberculosis, a gift of $1,000 or more annually, by Mr. B. P. Martinez.

Cincinnati General Hospital, a monthly payment of $10 from the pay of O. W. Cuhn, a sailor in the United States Navy, in gratitude for treatment received at the hospital.

That Confounded Comma.—A thousand and one stories have been published regarding the havoc caused by the misplaced coma. Sometimes this havoc is amusing; sometimes it is serious; and sometimes it is between the two. The havoc caused by a misplaced comma in our columns two weeks ago comes under the last designation. Commenting on Dr. Keen's article on the operation on President Cleveland, we wrote:

> "While the article is not of particular scientific or surgical importance, historically it is of decided interest."

The intelligent compositor, however, thus gave it to our readers:

> "While the article is not of particular scientific or surgical importance historically, it is of decided interest."

Lane Medical Lectures.—The sixteenth course of Lane Medical Lectures at Stanford University, San Francisco, will be delivered by Dr. Simon Flexner, director of laboratories of the Rockefeller Institute for Medical Research, New York, on the evenings of October 8 to 12 inclusive in Lane Hall. The chief subject will be "Physical Basis and Present Status of Specific Serum and Drug Therapy." The titles of the separate lectures are as follows:

October 8: Epidemic Meningitis; Lobar Pneumonia; Bacillary Dysentery and Specificity in Bactericidal Sera.

October 9. Gaseous Gangrene; Shiga Bacillary Dysentery, and The Principles of Homoserum Therapy.

October 10: Poliomyelitis and the Principles of Homoserum Therapy.

October 11: Local Specific Therapy as Illustrated by the Serum Treatment of Epidemic Meningitis, Poliomyelitis and Tetanus.

October 12: Chemotherapy of the Spirochetal Infections.

Clinical Congress of Surgeons.—The meeting of the Clinical Congress of Surgeon of North America will be held in Chicago, beginning Monday, October 22, and continuing to and including Friday, October 26. The opening meeting will be held in Orchestra Hall at 8:15 p. m., October 22, at which will be delivered the addresses of the retiring president, Dr. F. B. Lund, Boston, of the incoming president, Dr. John G. Clark, of Dr. Franklin Martin, of the Advisory Committe of the Council of National Defense, and of Dr. A. J. Ochsner, chairman of the committee of arrangements. The meeting will be given a military tone by the presence of the Surgeons-General of the Army, Navy and Public Health Service, Gorgas, Braisted and Blue, Col. T. H. Goodwin, and Sir B. G. A. Moynihan of the British medical services, Col. C. Dircle, France, and Dr. George W. Crile, recently in France. The scientific meetings of Tuesday, Wednesday, Thursday and Friday will be held in the Gold Room of the Congress Hotel. The presidential address will be given Thursday night, October 25, at 8 p. m., by President John G. Clark, his subject being, "Radium in the Treatment of Cancer of the Uterus." The articles to be read and the discussions are expected to have a distinct military bearing. The day work of the Congress will be made up of clinics at the various hospitals.

Health in the Canal Zone.—The report of the Health Department of the Panama Canal for July, 1917, shows that the health of the population in the Zone terminal cities was good. Whooping cough was prevalent in Balboa and Gatun districts. One case of infantile paralysis occurred in the Pedro Miguel district in a child aged 3 years, without history of contact with any previous case. Two cases occurred in December, 1916, in the Balboa district, also without history of outside contact. This case of infantile paralysis was the only one of disease of quarantinable nature occurring during the month. Among the 32,587 employees of the Panama Canal and the Panama Railroad Company, there were 908 admissions to hospitals and quarters. Deaths from all causes numbered twenty-five, of which twenty-four were from disease. Diseases causing the highest admission rate to hospitals were, in the order of their numerical importance, venereal diseases, malaria, tuberculosis, organic diseases of the heart, and pneumonia. These five diseases, it is said, caused 35 per cent. of all admissions. Venereal diseases caused 14 per cent., and malaria 13 per cent. of admissions. In the civilian population of the Zone, numbering 24,038, there were thirty-five deaths, thirty of which were from disease. Of the deaths from disease, 47 per cent. occurred among children under 4 years of age. Sixty births were reported for the month. There were nine deaths among children under 1 year of age, all colored. The death rate from disease among the employees of the Zone was 8.84 per thousand, and among the civilian population 14.90 per thousand.

FOREIGN

Deaths in the Profession Abroad.—**F. A. Arango,** a prominent surgeon and obstetrician of Colombia, aged 62.——**A. da Graça Couto,** professor of ophthalmology at the University of Rio de Janeiro and director-general of the public health service, aged 53.

Marriages

Lieut. Harry Clark Hackman, M. R. C., U. S. Army, Flint, Mich., to Miss Edna J. Wheeler of Bellevue, Pa., September 15.

Raymond Rudolph Barbanell, M.D., San Francisco, to Miss Henrietta Hurwitz of Covina, Calif., in Los Angeles, September 13.

Lieut. Fletcher Barr Taylor, M. R. C., U. S. Army, to Miss Virginia Barnes of Leavenworth, Kan., September 8.

Major Kerwin Weidman Kinard, M. C., U. S. Army, to Miss Ada Lee Porter of Kansas City, Mo., October 10.

Jacob Richter Buchbinder, M.D., Chicago, to Miss Hazel H. S. Felman of Joliet, Ill., in Chicago, September 27.

John Francis Ahern, M.D., Springfield, Mass., to Miss Anna G. Byrnes of Worcester, Mass., September 17.

Homer Augustus Alexander, M.D., Topeka, Kan., to Miss Mary Helen Poage of Marshall, Mo., September 19.

John Ray Johnson, M.D., Lima, Ohio, to Miss Hallie Hawk of St. Marys, Ohio, at Monroe, Mich., August 2.

Lieut. Jacob A. Goodman, M. R. C., U. S. Army, to Miss Ida E. Ginsburg, both of Chicago, September 26.

Felix E. Baker, M.D., Stamps, Ark., to Miss Margaret Burleson of Wortham, Texas, September 9.

Francis Bonneau Johnson, M.D., to Miss Ritchie McGrann, both of Washington, D. C., September 11.

Chester Henry Keogh, M.D., Chicago, to Miss Katharine Knapp of Portland, Ore., August 9.

Joseph Florian Konapa, M.D., to Miss Marie Kasperek, both of Chicago, in August.

George D. Bowdoin, M.D., Wilmington, N. C., to Miss Christine Johnson, recently.

Deaths

Americus R. Allen, M.D., Carlisle, Pa.; University of Pennsylvania Philadelphia, 1887; aged 55; a Fellow of the American Medical Association; chief surgeon for the Cumberland Valley Railroad, and the Cumberland Valley Traction Company; a member of the staff of the Carlisle Hospital, and surgeon to Todd Hospital; died at his home, September 15, from septicemia due to an operation wound.

Arthur H. Bernstein, M.D., Scranton, Pa.; Jefferson Medical College, 1891; aged 54; formerly a Fellow of the American Medical Association; a member of the Medical Society of the State of Pennsylvania; for several years a member of the surgical staff of the Scranton State Hospital; died at his home, September 20, from cerebral hemorrhage.

Otto Saly Binswanger, M.D., Portland, Ore.; University of Maryland, Baltimore, 1882; aged 63; a Fellow of the American Medical Association; professor of organic chemistry in the University of Oregon, Portland; a member of the medical staff of St. Vincent's Hospital; a veteran of the Franco-Prussian War; died at his home, September 25.

Robert McAllister Richardson, M.D., Chattanooga, Tenn.; Chattanooga (Tenn.) Medical College, 1908; aged 33; formerly a Fellow of the American Medical Association; a member of the Tennessee State Medical Association; a specialist on diseases of the eye, ear, nose and throat; died at his home, September 18, from tuberculosis.

Lieut. George Plummer Howe, M. R. C., U. S. Army, Boston; Harvard Medical School, 1904; aged 39; formerly a Fellow of the American Medical Association; a member of the Massachusetts Medical Society; is reported to have been killed in action, September 28, while on duty with the British forces in France.

William M. Baker, M.D., Shreveport, La.; Tulane University, New Orleans, 1874; aged 65; for many years a practitioner of Arcadia, La.; formerly a member of the Louisiana State Medical Association; for several years grand lecturer of the Grand Lodge, F. and A. M. of Louisiana; died at his home, September 24.

James Henry Elliott, M.D., West Plains, Mo.; Louisville and Hospital Medical College, Louisville, Ky., 1908; University of Louisville, Ky., 1909; aged 40; a Fellow of the American Medical Association, and president of the Howell County Medical Society; physician of Howell County; died at his home, September 24.

Peter Hughes, M.D., Brooklyn; New York University, New York City, 1879; aged 60; chief surgeon to St. Catherine's Hospital, Williamsburg, consulting surgeon to St. John's, St. Mary's and Jamaica hospitals; surgeon to the Brooklyn Ferry Company; died at his summer home, in Milford, Pa., September 30.

William Andrew Bindewald, M.D., Louisville, Ky.; University of Louisville, Ky., 1871; aged 76; formerly a Fellow of the American Medical Association; for thirty years physician to St. Joseph's Orphan Home; died in St. Joseph's Infirmary, Louisville, September 19, from disease of the stomach.

Jerome Samuel Bissell, M.D., Torrington, Conn.; Yale University, New Haven, Conn., 1894; aged 48; formerly a Fellow of the American Medical Association; a member of the Connecticut State Medical Society; died in a sanatorium in Waterbury, Conn., September 13, from nervous prostration.

Jesse Ralph Johnson, M.D., Amite, La.; Memphis Hospital Medical College, Memphis, Tenn., 1894; aged 52; formerly a Fellow of the American Medical Association; a member of the Louisiana State Medical Association; formerly coroner of Plaquemines Parish; died at his home, September 24.

Charles W. Nutting, M.D., Etna Mills, Calif.; Atlanta (Ga.) Medical College, 1876; aged 65; a Fellow of the American Medical Association, and past grand master of the F. and A. M. of California; for two years demonstrator of anatomy in his alma mater; died at his home, September 20.

Peter D. Fahrney, Hagerstown, Md. (license, Maryland); aged 74; a practitioner since 1867; formerly a clergyman of the Church of the Brethren; for more than thirty years a resident of Frederick, Md.; died at his home, September 22, from cerebral hemorrhage.

August George Horstman, M.D., Brooklyn; Cornell University, New York City, 1906; aged 39; a Fellow of the American Medical Association; formerly a member of the staff of the German and Jewish hospitals, Brooklyn; died at his home, September 26.

William James Francis Blaney, M.D., Baltimore; University of Maryland, Baltimore, 1896; aged 44; formerly a member of the Medical and Chirurgical Faculty of Maryland; died in St. Joseph's Hospital, Baltimore, September 25, from heart disease.

Bradbury Moulton Richardson, M.D., Brooklyn; New York Homeopathic Medical College, New York City, 1865; aged 75; from 1872 to 1880 surgeon of the Forty-Seventh Infantry, N. G. S., N. Y.; died at his home, September 23, from arteriosclerosis.

Andrew John Bilhoefer, M.D., New York City; New York University, New York City, 1885; aged 55; a Fellow of the American Medical Association; medical director of the Odd Fellows' Home; died at his home, August 28, from myocarditis.

Armistead Brooks Flippin, M.D., Nashville, Tenn.; University of Nashville, Tenn., 1857; aged 77; surgeon of the Eighth Arkansas Infantry, C. S. A., throughout the Civil War; died at his home, September 21, from cerebral hemorrhage.

Fred C. Dickson, M.D., Danville, Ill.; Indiana Medical College, Indianapolis, 1906; aged 36; formerly a Fellow of the American Medical Association; died in the Glen Rest Sanitarium, near Columbus, Ohio, September 20.

Benjamin F. Fortner, M.D., Vinita, Okla.; University of Nashville, Tenn., 1872; aged 70; a Fellow of the American Medical Association; for many years local surgeon for the Frisco system; died at his home, September 24.

Edward William Buhrmaster, M.D., La Harpe, Ill.; St. Louis College of Physicians and Surgeons, 1905; aged 37; who went to Colorado on account of his health; died in Colorado Springs, September 17.

Edwin Sharp, M.D., Argenta, Ark.; Vanderbilt University, Nashville, Tenn., 1881; aged 65; formerly a member of the Arkansas Medical Society; died in a sanatorium at Hot Springs, Ark., September 25.

George M. Wells, M.D., Wayne, Pa.; University of Pennsylvania, Philadelphia, 1895; for twenty-six years a practitioner of Wayne; died at the home of his son, near Annapolis, Md., September 24.

James M. Ferguson, M.D., Colorado Springs, Colo.; Medical College of the State of Carolina, Charleston, 1859; aged 89; a pioneer of the Pikes Peak region; died in Colorado Springs, September 25.

George H. Albright, Columbiana, Ohio (license, Ohio, 1896); aged 65; a member of the Ohio State Medical Association; died in the Salem (Ohio) City Hospital, September 21, from pneumonia.

Joseph Ferdinand Lindsey, Jr., M.D., Boston; Harvard Medical School, 1877; aged 67; who retired from practice about thirty years ago; died at his home in Roxbury, September 8, from angina pectoris.

James N. Riley, M.D., Stamping Ground, Ky.; Atlanta (Ga.) Medical College, 1857; aged 90; surgeon in the Confederate service throughout the Civil War; died at his home, September 18, from uremia.

Downing Howard Young, M.D., Wakeman, Ohio; University of Wooster, Cleveland, 1871; aged 71; a veteran of the Civil War; died at his home, September 10.

Robert Irvin McQuiddy, M.D., Lawrenceburg, Ky.; Jefferson Medical College, 1854; aged 86; died at his home, June 1, from senile debility.

Wellington C. Jeffers, M.D., Lindsay, Ont.; University of Victoria College, Coburg, Ont., 1867; aged 53; died at his home, July 17.

John Swope Mathias, M.D., Kansas City, Mo.; University of Maryland, Baltimore, 1879; aged 62; died at his home, September 17.

Floyd John Hodge, M.D., Florence, Mass.; Baltimore Medical College, 1908; aged 33; died in Plainfield, Mass., August 22.

John Allen Bernard, M.D., Minneapolis; University of Minnesota, Minneapolis, 1889; aged 71; died at his home, September 16.

Logan Cox, M.D., Hallidayboro, Ill.; University of Tennessee, Nashville, 1882; aged 55; died in East St. Louis, Ill., August 9.

Hugo Kinner, M.D., St. Louis; University of Berlin, Germany, 1863; aged 77; died at his home, September 11.

The Propaganda for Reform

In This Department Appear Reports of the Council on Pharmacy and Chemistry and of the Association Laboratory, Together with Other Matter Tending to Aid Intelligent Prescribing and to Oppose Medical Fraud on the Public and on the Profession

GONOSAN

Report of the Council on Pharmacy and Chemistry

The Council has adopted the following report on Gonosan and authorized its publication.

W. A. Puckner, Secretary.

Gonosan (Riedel and Company, Inc., New York City) comes in the form of capsules, each said to contain 5 minims of a mixture composed of oil of sandalwood 80 per cent., and 20 per cent. of alpha- and beta-resin of kava, isolated by a patent process. The mixture, as the name implies, is intended for the treatment of gonorrhea.

This proprietary preparation was under consideration by the Council at various times from 1905 to 1910. During this time, the Council agreed to accept the preparation if the suggestive name was changed, the therapeutic exaggerations abandoned, and the drug kava admitted to New and Nonofficial Remedies. The name was not changed, the other questions were left open, and the preparation was not accepted.

Recent and more objectionable advertising of Gonosan makes it advisable for the Council to take action and to publish a report. The tone of this advertising is reflected by the following quotation from a recent advertising circular:

> "The old-established balsamic treatment of gonorrhea, for some years neglected in favor of the local injection of organic silver and other germicidal salts, has, with the increasing knowledge and attention paid to the composition and purity of the balsams, regained to a large extent the confidence formerly reposed in them.
>
> "It may now be said that the combined treatment with local injections and internal administration of natural balsamic products completely dominates modern gonorrheal therapy."

Any one conversant with current medical literature and practice would stamp these statements as misleading exaggerations. The balsams, oleoresins and volatile oils may have some value as minor adjuvants in the treatment of gonorrhea, but that is all. The position in this respect has not changed materially in recent years. These agents do not have a value equal to that of local treatment, as the quoted statement implies.

The claims made for Gonosan might with equal force be made for oil of santal alone. Kava kava, the other constituent, belongs to the pepper family; it had a temporary vogue some two or three decades ago but has failed to maintain a place. It has never been recognized officially. There is no scientific evidence that it has any value either alone or as an adjuvant to sandal oil. The "clinical reports" quoted in the advertising circulars, rather curiously, nearly all date back ten years or more, viz., to a period when the attitude of the profession toward proprietary remedies was less critical than it is now. It would be interesting to know whether these authors still adhere to their opinion, or whether any of them have subsequently had experiences similar to that of a correspondent who wrote:

> "Gonosan, at my hands, did not prove to be of more essential value in the treatment of gonorrhea than any other sandalwood oil preparation. The various claims made for Gonosan, that it possesses sedative and anesthetic properties, that by its continuous use the urethral discharge disappears more rapidly and that, if combined with appropriate diet and rest, it is liable to prevent complications, are, according to my experience, not corroborated by actual results."

The only experimental work quoted in support of Gonosan, that of Pohl, is not convincing. The doses that Pohl found necessary to influence experimental purulent pleurisy makes it impossible to transfer his work to the clinic. (He found a dosage of oil of santal corresponding to an ounce per day, for man, inefficient; positive results were obtained only with 2 ounces per day.)

In order to learn the estimate placed on the therapeutic value of the "balsams," an inquiry was sent to the authors of the papers presented to the section of Genito-Urinary Diseases at the recent meeting of the American Medical Association in New York. The inquiry read:

> "*Dear Doctor:*—An advertising circular for Gonosan 'Riedel' which is now being distributed begins thus:
>
> 'The old-established balsamic treatment of gonorrhea, for some years neglected in favor of the local injection of organic silver and other germicidal salts, *has, with the increasing* knowledge and attention paid to the composition and purity of the balsams, regained to a large extent the confidence formerly reposed in them.'
>
> 'It may now be said that the combined *treatment* with local injections and internal administration of natural balsamic products completely dominates modern gonorrheal therapy.' "
>
> "Is the statement correct that the combined treatment with local injections and internal administration of *natural balsamic products* completely dominates modern gonorrheal therapy? Your reply to the above will be appreciated by the Council."

Seventeen replies were received. They bear out the position that has been outlined. Only one writer considered the statement even *approximately justified*, and this in the sense that "the majority of cases receive no other treatment" than a combination of local applications and systemic medication. Another stated that, "in a general way their statement is true though a trifle too sweeping," and then added that the field of the balsams is rather restricted. With the exception of these qualified endorsements the remaining (fifteen) replies characterized the statement as *incorrect and misleading*. The replies are a valuable contribution to the status of the "balsam" *treatment of gonorrhea*, and extracts of them are appended to this report.

It is recommended that the Council declare Gonosan inadmissible to New and Nonofficial Remedies, because the therapeutic claims are exaggerated (Rule 6); because there is no evidence that the combination of kava resin with oil of santal is superior to oil of santal alone (Rule 10); and because the therapeutically suggestive name is conducive of indiscriminate and unwarranted use of the preparation both by the profession and the public (Rules 4 and 8).

Appendix

The extracts from replies received to the inquiry above referred to, follow:

Dr. B., Penn., wrote:

"In my practice I have found that local injections are very valuable in the treatment of gonorrhea, but I have never found that the internal *administration of* natural balsamics dominated modern gonorrheal therapy; while it is an aid, I consider the quoted statement to be very erroneous."

Dr. F., D. C., wrote:

"While it is doubtless true that acute urethritis, gonorrheal, is *now* generally treated by local injections of solutions of organic silver salts, and that santal oil is often used, it is not true, as one would *infer* from the quotation, that the balsams are *now* considered more efficacious than they were formerly. So *far as I know* they have not lost or regained anything during the past dozen years in the way of confidence reposed in them. The *indications for their use* is very definite and very limited."

Dr. B., Ga., wrote:

". . . in recent years I have almost abandoned the use of balsams, etc., in the treatment of gonorrhea. Patients, who are properly treated otherwise, seem to get along as well without such drugs as with them, in fact apparently better for they *have no gastric* disturbance. It is important for patients to drink freely of water and when so doing the balsams are so diluted that I cannot conceive of their doing much good. Formerly my patients often lost weight during the treatment of gonorrhea; now without *balsams and with plenty* of water, they usually gain in weight."

Dr. S., Mich., wrote:

". . . we believe that in a general way their statement is true though a trifle too sweeping. We do not *ordinarily* use the balsams in uncomplicated anterior urethritis. We *do* however, find indication for their administration in *from* sixty *to* seventy five per cent. of all cases of acute gonorrhea at some time *during* the course of the disease."

Dr. L., Mo., wrote:

"I would say that the statement that, '*The combined* treatment with local injections and internal administration of natural balsamic products completely dominates modern gonorrheal therapy,' is far from representing the facts. While the balsamics may occasionally have an indirect soothing effect on the *mucous* membranes *involved, the dominant factor is local treatment,* aiming at disinfection and restoration to normal of the inflamed tissues."

Dr. R., Mich., wrote:

"Regarding *your request* although *I am willing* to reply it is difficult to do so because if I *should* do so *in the* affirmative that could apply only to certain acute cases without *complication* of any kind and such cases are rare. In such, however, the advertiser is not far from right—since vaccine therapy *has proven absolutely* worthless we must *fall back* on antiseptics in acute *urethritis when there* are no objections to such treatment . . ."

Dr. K., Ill., wrote:

"I am under the impression *that the internal* administration of balsamics is used *only* when *complications arise*, such as acute posterior urethritis. Personally I use the balsamics very, very rarely. From my observation, however, I am led *to believe* that many men still use internal drugs in the treatment of *gonorrhea*, and during the past few years, I should *say* the use of *hexamethylenamin* has been on the increase, and the *use of the balsamics* on the decrease. I do not believe that hexamethylenamin *is of any value in* the treatment of gonorrhea, and am *simply citing this as my observation* of the widespread use of this *drug in the treatment of gonorrhea.*"

Dr. T., Penn., wrote:

". . . I believe that *more men use salol* or hexamethylenamin, or *no urinary antiseptic* whatsoever, than use the balsamics."

Dr. B., Ind., wrote:

". . . The only *systemic treatment* that is considered *necessary* today is rest, plenty *of water and neutralize* the acidity *of the urine with bicarbonate of soda* or *some sodium salt.*"

Dr. Y., Mass., wrote:

"Sandal wood oil during the acute stage of *gonorrhea* certainly tends to make the patient more comfortable and undoubtedly does lend some (tho I believe slight) gonococcidal action. That it plays any *considerable* part in actual cure I *think* is *doubtful*. The statement as quoted is true in so *far as it states that* local *treatment plus internal medication* with a balsam comprises most of the modern treatment of gonorrhea but it is grossly *misleading in* that it lets one draw the *inference* that the *balsam plays a large if* not the principal part."

Dr. H., New York, wrote:

"*For a period of at least three years in my hospital, dispensary* and private practice, I conscientiously tried out most of the balsamics on the market (including Gonosan, which I favored for some time) both alone, and combined with local injections. As a result of this study, I have come to the conclusion that the balsamics have little, if any value in the treatment of gonorrhea. During the past few years I have relied almost entirely on local therapy, and seldom prescribed any of the balsams in my private practice, certainly in not more than five per cent. of the cases. My results I find are just as satisfactory, and my patients appreciate the fact that they are not loaded up with disagreeable medication. Instead of the balsamics, I am using sodium bicarbonate more and more, and feel convinced that the proper use of this drug is of more value than all of them combined."

Dr. K., Cal., wrote:

"The *statement that the combined* treatment with *local injections* and *internal* administration *of* natural *balsamic products* completely dominates modern gonorrheal therapy, would at present not be justifiable even with reference to the initial or acute stage of gonorrhea, while in the subacute and chronic forms of the disease local injections and balsams play an almost insignificant rôle as compared with various other recognized therapeutic measures."

Meningitis.—The first clearly recognized epidemic of cerebrospinal meningitis occurred in Geneva, Switzerland, in the spring of 1805, followed during the years of 1806 to 1814 by a number of scattered outbreaks in widely separated localities of France and Germany. Coincident with this first series of epidemics in Europe occurred a similar series in America, beginning with an outbreak at Medfield, Mass., in 1806, and continuing until 1819, visiting during this period many localities in the United States and reaching Canada. Since that time periods of epidemic or pandemic prevalence have alternated with periods of comparative rarity. From 1836 to 1850 epidemics appeared in Europe, in France, Germany, Austria, Italy, Spain, Ireland and Denmark and in Algeria. In America there was a succession of outbreaks from 1842 to 1850. In its third period of prevalence, from 1850 *to* 1860, the disease visited chiefly the Scandinavian peninsula, hitherto spared, causing over 4,000 deaths from *1854 to 1861*.—W. H. Frost.

Correspondence

"MEDICAL SCIENCE ON THE SIDE OF ALCOHOL"?

To the Editor:—Recently I received a pamphlet marked as a reprint from a daily paper published in a state where a prohibition campaign is shortly to be waged. The article purports to have been written by one of the oldest and most highly honored members of our profession. The virtues of alcohol are lauded and the action of the House of Delegates at the last annual session of the American Medical Association on the question of the use of alcohol is criticized as is also the position of other scientific and philanthropic organizations. Congress is censured and even the President criticized. It is evident that the pamphlet has been sent broadcast among physicians for the purpose of overcoming the effect of the action of the House of Delegates. The statements made in this article are not supported by up-to-date knowledge of the physiologic and therapeutic action of alcohol, and the arguments advanced are fallacious. The paper seems to be the expression of a personal opinion based on preconceived ideas which are contradictory to the opinions held by advanced thinkers and workers in the medical profession.

On the first page of the pamphlet appears the likeness of the venerable physician who is credited with being the author. Possibly, if they see only this likeness and read no more than the caption, the impression which those who circulate the booklet desire to produce may be made on the minds of certain time-pressed medical men. But any of those who stop to consider the article will not be misled into thinking that there still remains a word in favor of old King Alcohol. The circulation of the article seems to indicate that manufacturers and investors whose business is at stake are making a desperate effort to stem the tide of popular indignation against the use of alcohol. With the realization that millions of bushels of food-producing creals have been diverted from their use as a food for the manufacture of a worse than useless luxury, the public has been aroused to an appreciation of the situation and is clamoring for this grain to be used to feed the starving people of Europe and to relieve the growing food shortage here.

The medical profession, after careful scientific study, has come to appreciate the facts concerning alcohol and knows it to be a determining factor in estimating the increase in insanity, moral degradation, disease and crime. Social workers and religious teachers have shown the impossibility of accomplishing reform while the rum demon is abroad. It must be eliminated. Evan O'Neill Kane, M.D., Kane, Pa.

To the Editor:—I am enclosing a pamphlet, recently received by me, and similar copies may have been sent to all the physicians in the United States, including yourself, "Compliments of" whom, not divulged.

I cannot refrain from protesting against both the motive for sending such an article, and also the attempt to create the impression that the leading physicians of the United States sanction such assertions as it contains. I have practiced long enough to learn the evil effects of so-called continued moderate use of alcohol, on the recuperative powers in sickness and accidents, both in young and aged persons. I am aware of the reasons why alcohol is forbidden to athletes in training; why members of big corporations believe better work and fewer accidents are obtained by selecting workmen who do not use it; why a large percentage of crimes is laid to the influence of alcohol intake, thus filling our jails and asylums, for which the people are being taxed; why the laboring class would better itself and families by leaving alcohol alone; why better work has been done by the big armies by excluding or restricting its use; why its influence is always degrading.

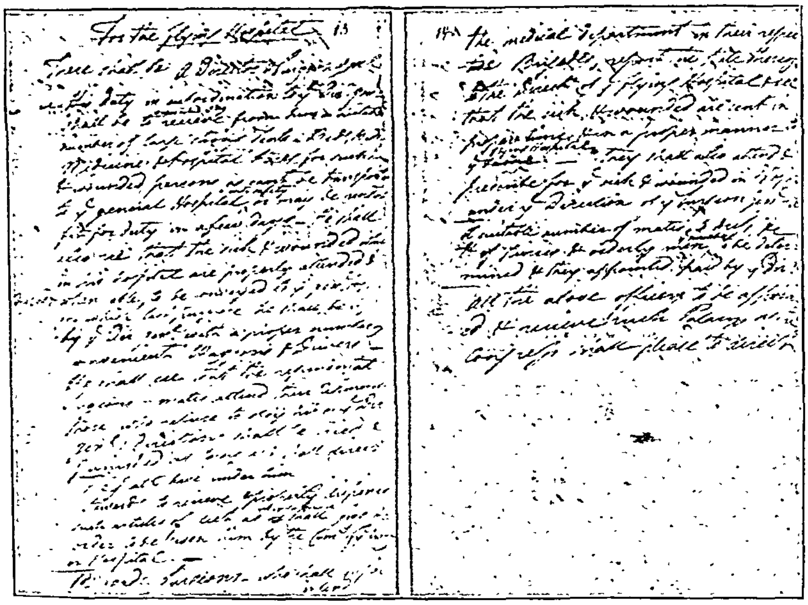
It is not a question of treating a few sick persons; it is a broader, unselfish economic question, involving millions of people. Consequently, I believe I am only one of a large number of physicians who stand ready to sacrifice alcohol for other stimulants and drugs, for the uplift of humanity.

Charles E. Hawkes, M.D., Providence, R. I.

ORIGIN OF THE FLYING HOSPITAL

To the Editor:—In view of your editorial, "Larrey the Originator of Rapid Evacuation of the Wounded" (The Journal, Sept. 29, 1917, p. 1084), the enclosed copy of the scheme written by William Shippen and John Cochran, both of whom were at a later date Surgeons-General in the Army of the Revolution, and in the handwriting of William Shippen, may be of interest to you. This appears in No. 22, folio 9, papers of the Continental Congress, and was transmitted to Congress by Washington, Feb. 14, 1777, and was reported on by the committee, Feb. 24, 1777. It is of decided interest, showing as it does where the "flying hospital" originated. I can find no record that this scheme was actually enacted into a law or of its having been in use in the Continental Army, but it was suggested by William Shippen in 1777 and was a matter of record before the Continental Congress in the handwriting of William Shippen of that date.

W. O. Owen, M.D., Washington, D. C.



Plan for flying hospital as written by William Shippen in 1777.

FOR THE FLYING HOSPITAL

There shall be a Director & Surgeongenl whose duty in subordination to y-e Dir.-r genl shall be to superintend & reg. receive from him a suitable number of large strong Tents—Beds, Bedding, Medicine & Hospital Stores for such sick and wounded persons as cant be transported to y-e general Hospital with safety or may be rendered fit for duty in a few days.—He shall also see that the sick & wounded while in his hospital are properly attended & dressed & when able, to be conveyed to y-e gen-l Hospital for which last purpose he shall be supplied by y-e Dir. gen.-l with a proper number of convenient Waggons & Drivers.—He shall see that the regimental Surgeons and mates attend their regiments; those who refuse to obey his or y-e Dir. gen-l's directions shall be tried & punished as Congress shall direct.

He shall have under him Stewards to receive & properly dispense such articles of diet as ye Director General shall give or order to be given him by the Com-y of y-e Army or Hospital.—

Brigade Surgeons who shall superintend the medical department in their respective Brigades, report the State thereof to the Direct-r of y-e flying Hospital & see that the sick & wounded are sent in proper time & in a proper manner to y-e flying hospital. They shall also attend & prescribe for y-e sick & wounded in y-e Hospital under y-e Direction of y-e Surgeon Gen-l of a suitable number of mates to dress. &c & of Nurses and orderly men y-e number to be determined & they appointed & paid by y-e Dir-r., all the above officers to be appointed & receive such Salarys as the Congress shall please to direct.

BELGIAN AND FRENCH PHYSICIANS' FUND

To the Editor:—I append the list of subscriptions which I have received (all of them in cash, up to the present time) for transmission to our Belgian and French colleagues to help in reestablishing themselves in their homes and offices. I hope that this sum may be increased above $1,000 and shall hold it for a short time in the hopes that it may reach a considerably larger sum.

When one remembers the number of physicians in these devastated districts and their utter destitution of everything for home and office or practice, $1,000 will go but a very little way in helping a very few.

SUBSCRIPTIONS IN CASH

Dr. Frederick C. Shattuck, Boston	$ 50.00
Dr. Richard Dewey, Wauwatosa, Wis.	10.00
Dr. Richard Lewisohn, New York	50.00
Dr. W. W. Keen, *Philadelphia*	100.00
Dr. Joseph Walsh, Philadelphia	10.00
Dr. J. T. Foley, Lewiston, Mont.	25.00
Dr. Helen C. Putnam, Providence, R. I.	100.00
Dr. J. J. Winn, Norwood, Ohio	10.00
Dr. L. H. Finch, Amsterdam, N. Y.	10.00
Dr. Maud J. Frye, Buffalo	5.00
Dr. Glennis E. Humphrey, Cambridge Springs, Pa.	5.00
Dr. R. O. Raymond, Flagstaff, Ariz.	15.00
"A Friend," Keystone, W. Va.	10.00
Dr. H. Gifford, Omaha	500.00
"A Friend," New York	10.00
Dr. George H. Simmons, Chicago	10.00
	$920.00

Besides these gifts of money I have received from several of those in the list gifts of instruments, some of them of very considerable value. I have also received from a friend in New York an eight plate static electric machine, and from two friends, a man and a woman, both of Plymouth, Mass., a considerable number of valuable instruments.

To any friends who wish to send instruments and other appliances I must suggest that if the apparatus or instruments require repairs, it would be necessary to have these done in this country as the means for repairs, I am told on good authority, are almost universally lacking. The polishing and sharpening I would suggest should not be done in this country, for it can be done much more cheaply abroad and also will give occupation to some of the disabled soldiers themselves.

I have also to acknowledge the great kindness of Charles Lentz & Sons of this city for listing and packing many of these instruments.

W. W. Keen, M.D.,
1729 Chestnut Street, Philadelphia.

THE MORAL OBLIGATION OF THE MEDICAL INTERN TO THE HOSPITAL

To the Editor:—For some years it has seemed desirable that hospitals throughout the country establish among themselves a rule of ordinary decorum relating to applications for appointment to hospital internships. It is notoriously the fact that with few exceptions the recent graduate in medicine has little regard for the contract he makes with the hospital authorities. Very commonly capital is made of the prestige acquired by a hospital appointment in the securing of one elsewhere. An energetic canvasser during his two weeks' summer holiday may "come up" with several good things, as he describes them, and secure options for his friends. He may decide not to come back at all after his vacation and lend himself as a decoy to secure a bevy of interns for his new employer. He will write back to the fellows at his "dear old Alma Mater" and assure them he can fix them. Any curtailment of privileges involved in ordinary hospital staff discipline will furnish cause for a one sided abrogation of his contract and lead to his taking advantage of the offer from another hospital which is at that moment in his pocket.

Among respectable people, it is not customary to dicker with a neighbor's employees, to entice them with promises of better wages, better food, better housing, better opportunities or improved social surroundings. There is no such delicacy on the part of the average hospital management. The restless intern of another hospital will be gathered in without a question. He is not required to have a "character" but is taken on his looks, and without any solicitude as to a proper release from his previous contract.

It is suggested that hospital officials would improve their own morale and that of successive groups of young professional men by establishing among themselves a simple code by which to discourage the unfortunate laxity of professional obligation and duty which in that particular they now condone.

William F. Lockwood, M.D., Baltimore.

THE VENEREAL DISEASES

To the Editor:—In The Journal that has come to me this morning, as well as those of the past weeks, I have read the article under the caption "The Venereal Diseases." Kindly accept my congratulations for your continued discussion of a subject which is of vital interest to every physician and, we must admit, altogether too little understood.

I feel compelled to take exception to a most egregious error which has been published in the serial article of October 6. On page 1171 there occurs the statement that "when other methods fail to relieve tenesmus and pain [in acute posterior gonorrhea], remarkable relief is occasionally obtained by the instillation of a few drops—about ten—of a 1:500 to 1:100 solution of silver nitrate through a soft catheter or deep urethral syringe," etc.

It is admitted later on in the article that such a procedure is "contrary to the principles" of the treatment of acute posterior gonorrhea, and it is cautioned that such should be employed only as "a last resort." The introduction of any instrument into a urethra acutely infected with the gonococcus should be absolutely and emphatically forbidden without exception. Such a procedure is always attended with a high probability of the production of an epididymitis or some other equally serious complication, and should never be attempted.

Further than that, 1 per cent. of silver nitrate injected into even a normal posterior urethra is always followed by more or less annoying tenesmus—the very condition that one attempts to relieve by such an instillation.

James C. Sargent, M.D., Milwaukee.

AN APPEAL FOR WOMEN ON HOSPITAL STAFFS

To the Editor:—In the midst of the urgent appeals on the one hand for more physicians for the Army, and on the other hand the equally urgent appeals not to weaken our medical forces at home, I am moved to ask why the women physicians are not being utilized to fill in the broken ranks and to prevent in a large measure the crippling of our hospitals.

The need for physicians that exists in the warring countries makes its appeal to every man of red blood: and to every woman too. But the men can respond by going; the women cannot.

The war office in Washington refuses the women passports, refuses the offers of well-equipped units, refuses at every turn to avail the government of their services in any way, so that the fact that our medical women are not allowed to take part in the defense of their country cannot in any way reflect on themselves.

In this war, however, in which only the fullest use of all our resources will work toward the ultimate success of our arms, we cannot afford longer to ignore that body of trained women which stands ready to do its part. With the same training and the same license to practice as our medical men, they can be depended on to safeguard the health of the community and by so doing loose the bonds that prevent every man of proper age from springing to his country's call.

Even in conservative England many of the largest London hospitals have women on their staffs, and Sir Alfred Keogh, Surgeon-General of the British Army, in a recent communication to this country says, "Do not underestimate the value of the women physicians; their assistance has been invaluable."

Eoline C. Dubois, M.D., Springfield, Mass.

REST FROM VOCALIZATION IN THE TREATMENT OF LARYNGEAL TUBERCULOSIS

To the Editor:—From time to time articles appear in the journals on the treatment of laryngeal tuberculosis, and it seems strange that so little importance is attached to total nonuse of the voice. In fact, authors generally seem to take it for granted that partial or complete rest will be required; but even so eminent an authority as Ballenger does not even mention it in his textbook. In my experience, absolute rest from phonation has produced far better results than any local applications. In an article on "Rest in the Treatment of Laryngeal Tuberculosis" read before the American Laryngological Association in 1905 (*Tr. Am. Laryngol. Assn.*, p. 149; *Am. Jour. Med. Sc.*, 1905, **131**, 300), stress was laid on the necessity for absolute rest in the successful treatment of this intractable malady. Since then cases have been reported in which the larynx was rested from three to eighteen months with most gratifying results. It has been my custom to demand from every patient consent for absolute rest before undertaking the care of tuberculous cases. Tuberculomas, ulceration, etc., usually form only in the later stages of the disease, and the systemic infection is usually so great by that time that but little hope of success may be expected from any form of treatment. Even then, however, absolute rest with anodyne applications will give more relief than curettage, epiglottectomy or the application of the galvanocautery. It seems, therefore, that absolute rest from phonation should be required in all cases and at all stages irrespective of any other measures that may be instituted.

W. Peyre Porcher, M.D., Charleston, S. C.

Anonymous Communications and queries on postal cards will not be noticed. Every letter must contain the writer's name and address, but these will be omitted, on request.

SALKOWSKI-KOJO TEST FOR COLLOIDAL NITROGEN IN THE URINE

To the Editor:—In The Journal, Sept. 15, 1917, p. 941, you refer to the Salomon-Saxl test, with which I am familiar; also to the Salkowski-Kojo test with which I am not familiar. What is the latter, or where can I find it?

C. H. Walker, M.D., New York.

Answer.—In the article summarized on page 941, Kahn states that Salkowski and Kojo have recently (1910) suggested several methods for determination of the colloidal nitrogen in the urine, and in 1911 Kojo published (*Zeitschrift für physiologische Chemie*, 1911, **73**, 416) the results of a comparative study of the various procedures suggested in this connection. Kahn tabulates the findings in 128 cases, including twenty-two healthy persons and fifty-nine with cancer, tested by the Salomon-Saxl method and for the colloidal nitrogen. The technic used for the latter he describes as follows: "The urine was first tested for coagulable protein which, if found, was removed by means of heat coagulation, with addition to the boiling liquid of a few drops of dilute acetic acid. To 100 c.c. of a mixed, filtered, twenty-four hour specimen of urine, zinc sulphate was added in sufficient quantity to effect saturation. The saturated liquid was allowed to stand for twenty-four hours, then filtered through ashless paper, and the precipitate washed several times on the paper with saturated zinc sulphate solution to remove nitrogenous substances adherent to the precipitate. The paper and precipitate were then placed in a Kjeldahl flask and the nitrogen content determined by the Kjeldahl method. The total nitrogen in 5 c.c. of urine was also determined by the Kjeldahl method. The ratio of the nitrogen in the zinc sulphate precipitate to the total urinary nitrogen was computed." In the healthy the nitrogen value for the zinc sulphate precipitate, as compared with those for total nitrogen, varied from 1.25 to 2.15, with an average of 1.67 per cent. In the fifty-nine cancer cases the range was up to 5.75 per cent. of the total nitrogen, the minimum being 3.4 per cent. Fifty-eight of the fifty-nine cases of cancer gave a positive Salomon-Saxl reaction.

SURGICAL AND MEDICAL INCIDENTS IN THE BIBLE

To the Editor:—I am asked to give a talk on the surgical and medical incidents found in the Bible from a modern standpoint. Kindly refer me to some literature that will help me in preparation.

Eugene A. Hensel, M.D., San Diego, Calif.

Answer.—We may refer you to the following articles:

MAKING WATER SAFE FOR DRINKING PURPOSES

To the Editor:—In an irrigated district where drinking water can be had only from cisterns filled from irrigating ditches, what is the best method of rendering the water safe for drinking purposes? Assuming that chemicals are to be used, what is the highest harmless concentration, the lowest effective? What is the most effective way to remove or precipitate fine silt?

Please omit my name.

O. B. L.

Answer.—Chlorinated lime is most generally used for sterilization of drinking water, 1 part of available chlorin per million being sufficient (The Journal, Jan. 27, 1912, p. 279). Recently halazone tablets have been proposed for water disinfection (The Journal, Oct. 6, 1917, p. 1166). Very full description of water purification methods are given in "Water Purification Plants and Their Operation," by Milton F. Stein, John Wiley and Sons, New York, 1915. The book contains excellent diagrams and accurate data as to amount of coagulent to be used, cost of operation, etc. Good general information on water supplies may be found in "Clean Water and How to Get It," by Allen Hazen, John Wiley and Sons, 1914.

OCHSNER'S SOLUTION

To the Editor:—Kindly give the ingredients and their proportions in Ochsner's solution.

A. P. H.

Answer.—Ochsner's solution consists of phenol (carbolic acid), 0.5 per cent.; aqueous saturated solution of boric acid, 66 per cent., and alcohol, 33 per cent.

Familial Polyadenomatosis in the Rectum.—A. Oidtmann has encountered eight cases of this kind, and six of the patients belonged to two families, three sisters in one family, and mother, son and daughter in the other. One of the three sisters succumbed to hemorrhages; the others were cured by resection of the protruding bunches. The *Nederlandsch Tijdschrift voor Geneeskunde* publishes his report in Society Proceedings, 1917, **1**, 2184, with illustrations, and references of nine other families showing from two to six cases of polyadenomatosis. A cancerous tendency was evident in eight of the total twenty-seven cases in this group, and in all but three of Oidtmann's own eight cases.

Medical Education and State Boards of Registration

COMING EXAMINATIONS

Arkansas: Little Rock, Nov. 13-14. Sec., Dr. T. J. Stout, Brinkley.

Arkansas: Eclectic: Little Rock, Nov. 13. Sec., Dr. C. E. Laws, 803½ Garrison Ave., Fort Smith.

Connecticut: New Haven, Nov. 13-14. Sec., Dr. Charles A. Tuttle, 196 York St., New Haven.

Connecticut: Homeopathic: New Haven, Nov. 13. Sec., Dr. E. C. M. Hall, 82 Grand Ave., New Haven.

Connecticut: Eclectic: New Haven, Nov. 13. Pres., Dr. J. W. Fyfe, Saugatuck.

Maine: Portland, Nov. 13-14. Sec., Dr. Frank W. Searle, 776 Congress St., Portland.

National Board of Medical Examiners: Chicago, Oct. 10-18. Sec., Dr. J. S. Rodman, 2106 Walnut St., Philadelphia.

Nevada: Carson City, Nov. 5. Sec., Dr. S. L. Lee, Carson City.

New Jersey: Trenton, Oct. 16-17. Sec., Dr. Alexander MacAlister, 438 E. State St., Trenton.

South Carolina: Columbia, Nov. 13. Sec., Dr. A. Earle Boozer, 1806 Hampton St., Columbia.

Texas: Dallas, Nov. 20-22. Sec., Dr. M. F. Bettencourt, Mart.

West Virginia: Clarksburg, Nov. 21-23. Chairman, Dr. S. L. Jepson, Capitol Bldg., Charleston.

Medical Colleges of the United States Recognized in Canada

A report received from the Medical Council of the College of Physicians and Surgeons of Ontario states that in June, 1917, the following medical schools of the United States were given recognition:

Leland Stanford Junior School of Medicine, San Francisco.
University of California Medical School, San Francisco.
Yale University School of Medicine, New Haven.
Northwestern University Medical School, Chicago.
Rush Medical College, Chicago.
Indiana University School of Medicine, Indianapolis.
Johns Hopkins University Medical Department, Baltimore.
Harvard University Medical School, Boston.
University of Michigan Medical School, Ann Arbor.
University of Minnesota Medical School, Minneapolis.
Washington University Medical School, St. Louis.
University of Nebraska College of Medicine, Omaha.
Columbia University College of Physicians and Surgeons, New York City.
Cornell University Medical College, New York City.
Syracuse University College of Medicine, Syracuse.
Ohio State University College of Medicine, Columbus.
Western Reserve University School of Medicine, Cleveland.
Jefferson Medical College of Philadelphia.
University of Pennsylvania School of Medicine, Philadelphia.
University of Pittsburgh School of Medicine, Pittsburgh.

The report states that graduates of the above schools, under certain limitations, will be permitted to take the examination for the license to practice medicine in Ontario. An extract from the regulations is as follows:

"Students graduating subsequent to July 1, 1916, from 'recognized' medical colleges in any of the United States shall submit a certificate from that state board of licensure that the candidate is fully qualified for admission to the examination of that state board. Certificates will be accepted from state boards (1) which accept similar certificates from this Council and (2) whose standards are equivalent to those of this Council."

Washington January Examination

Dr. C. N. Suttner, secretary of the State Board of Medical Examiners of Washington, reports the written examination held at Spokane, Jan. 2-4, 1917. The examination covered 11 subjects and included 110 questions. The percentage required to pass was 75. Thirty-four candidates were examined, of whom 27 passed, including 5 osteopaths, and 7 failed, including 2 osteopaths. The following colleges were represented:

PASSED	Year Grad.	Total No. Licensed
College	(1916)	1
George Washington University	(1900)	1
American Medical Missionary College	(1912) (1914)	2
Northwestern University	(1915)	1
Rush Medical College	(1914) (1915) (1916)	3
University of Illinois	(1913)	1
Drake University	(1904)	1
Hospital College of Medicine, Louisville	(1916)	1
University of Michigan Med. School	(1916)	1
University of Minnesota		
National University of Arts and Sciences	(1916)	1
John A. Creighton Medical College	(1912)	1
Jefferson Medical College	(1911) (1913) (1915)	3
Woman's Medical Coll. of Pennsylvania	(1909)	1
Nagasaki Special Medical School	(1903)	1
Nippon Special Medical School	(1912)	1
Okayama Special Medical School	(1901)	1
Sai Sei Medical College, Tokyo	(1904)	1
FAILED		
University of Louisville	(1912)	1
Saginaw Valley Medical College	(1902)	1
Barnes Medical College	(1905)	1
Kyushu Imperial University	(1913)	1

Medicolegal

Illegal Prescribing of Intoxicating Liquor

(City of Seattle vs. Hewetson (Wash.), 164 Pac. R. 234)

The Supreme Court of Washington affirms a conviction of the defendant, a licensed physician, who was charged with having issued a prescription for whisky, without having any good reason to believe that the person to whom it was issued was actually sick, or that the liquor was required as medicine. The court says that the evidence showed that the defendant had an office in the back part of a room occupied by a drug store. That the office could be entered by a door from the portion of the building used for the drug store. That on the evening of Feb. 19, 1916, the complaining witness went to the defendant for the purpose of getting a prescription for liquor. That he entered through the drug store, found seven or eight persons standing in line, waiting for similar prescriptions, and, when his turn came, said to the defendant that he had a cold, or a bad cold. That thereupon the defendant inquired of him if he would like a little stimulant, to which he replied, "Yes." That before receiving the prescription he was required to sign a statement as follows: "I, the undersigned, do declare that the prescription written for me by Dr. J. W. Hewetson for intoxicating liquor, on this date is for medical purposes; that I am sick and in need of medicine, and will take the same according to directions. Dated this 19th day of February, 1916. M. W. Palmer, 135 N. 75th St." That there was no examination of the complaining witness as to his physical condition. The evidence further showed that the record book and the prescription file at the drug store disclosed that, February 19, 164 prescriptions for liquor had been filled; February 18, 103; February 17, 105, and February 16, 83—and that most of these prescriptions had been written by the defendant. It was admitted, on the trial, that any one "could get a prescription for intoxicating liquor unless he refused to sign one of these statements," and that the defendant had "for the past two years written prescriptions free of charge." There was also some evidence as to the number of persons standing in line, waiting to have prescriptions written, on other occasions than the one above referred to. Under this evidence, and other details that appeared in the testimony, the question whether the defendant had ground to believe that the person to whom he issued the prescription was actually sick, or that liquor was required as medicine, was for the determination of the jury. It could not be held, as a matter of law, on such evidence, that the plaintiff had failed to prove that the defendant, when he issued the prescription for which he was being tried, did not have good reason to believe that the person to whom it was issued was actually sick, and that the liquor was required as medicine. The real issue in such a case is whether the prescription was given in good faith, and, as bearing on this question, the number of prescriptions given by the accused, within a specified time, for intoxicating liquor, to various persons, as found on the file of the druggist, in whose store the defendant kept his office, was competent. The sections of the city ordinance which the defendant was charged with violating were regulative in their nature, and, in passing such an ordinance, the city acted within its power.

AMERICAN ASSOCIATION OF OBSTETRICIANS AND GYNECOLOGISTS

Thirtieth Annual Meeting, held at Newark, N. J., Sept. 17-19, 1917

The President, Dr. John W. Keefe, Providence, R. I., in the Chair

Fundal Hysterectomy to Reduce the Menstruating Surface

Dr. Gordon K. Dickinson, Jersey City, N. J.: Fundal hysterectomy, done through the vagina, is a simple, safe and effective procedure. After a purse-string has been placed around the anus, a clip is applied to each labium, which is retracted open. Into the vagina is poured an ounce or more of 3.5 per cent. tincture of iodin, which is allowed to remain while the patient is being draped. When everything is ready, a volcellum is put on the cervix and it is brought down. A transverse incision is made anterior to the cervix, the bladder is separated from the uterus, the peritoneal cavity is opened, and the fundus is brought into the vagina. Clips are applied alongside the uterus to compress the circulation slightly and to act as retractors. A V-shaped incision is then made through the substance of the uterus for various depths, depending on the extent of the disease as estimated by the hemorrhage. This is *not* made too close to the fornix because the object is not so much the reduction in size of the uterus as the reduction of the menstrual surface. After this wedge-shaped piece is removed, both fornices should be cauterized thoroughly. If not, they will respond at the menstrual period, and, producing tension, give rise to pain. The cervical portion should also be touched for aseptic reasons. The part removed is carefully inspected for any appearance of malignancy. With a small, sturdy, curved needle the two flaps are approximated, stanching hemorrhage. The peritoneal surface is further brought together by running catgut, the clips are removed, the uterus is pushed back into place, and the anterior colpotomy wound sutured.

DISCUSSION

Dr. Albert Goldspohn, Chicago: Some obstetricians may object to opening the abdomen and cutting the uterus in order to find out what is wrong in it. More efficient work can be done medically to help some of these cases that are not extremely bad. Tincture of iodin applied effectively to the endometrium, say about twice a month, will make it unnecessary to operate in many of these cases. Zinc chlorid will be needed once in a while, and although it is destructive, it will do the work. If zinc chlorid is to be applied well to the endometrium, it is necessary to dilate the cervical canal. The woman will need to have morphin, or the cervical canal must be anesthetized with phenol (carbolic acid) or cocain. Ample dilation is made under a clean technic. The application is made with some kind of syringe applicator, the cervical canal being cauterized extensively, but not the fundus. Then the zinc chlorid is introduced without any difficulty. Treatment of this kind does much more good than any mechanical curettement.

Dr. Hugo O. Pantzer, Indianapolis: To ablate the entire endometrium would inflict unnecessary violence on the sexual function and on the chemism of the whole body, and we should hesitate to use the cautery for the destruction of the endometrium. It is better to remove only a part of the endometrium, as suggested by the essayist. I wonder whether we ought to regard these cases as toxemias due to a focal infection.

Physical Conditions in Women Warranting Sterilization

Dr. E. W. Hedges, Plainfield, N. J.: There are conditions when sterilization will save lives that otherwise would be sacrificed. The operation is indicated when a woman has had eclampsia in two successive labors or when real diabetes exists. Chronic nephritics should never marry or conceive. The same rule applies in cases of pulmonary tuberculosis. Both diseases are aggravated by pregnancy, and a fatal termination is hastened. Patients with bad cases of heart decompensation should not conceive. The vast majority of the children in such cases die in abortion, premature labor or stillbirth, and a third of the mothers needlessly lose their lives. In all the classes of cases mentioned, the children, even if born alive, enter life with a physical handicap, and the risk for the mother is so great that it should be prevented by sterilization. If seen first when pregnancy has commenced, an abdominal hysterotomy and sterilization should be done at the same time. If the child is near viability, an attempt may be made to tide the patient over a short time and then bring on labor. As to pyosalpinx, if the woman is well to do, she should be let alone with a nurse and a fountain syringe and an easy chair; but if she has to earn her living, her tubes should be taken out and her health restored. Persons with certain forms of insanity, the feebleminded and idiots, as well as epileptics, should be cared for in institutions; but if the patient lives at home, the question of sterilization should be considered.

DISCUSSION

Dr. Edward J. Ill, Newark, N. J.: Dr. Hedges has touched on a question that is going to be abused just as much as was the removal of the uterus or the ovaries. The sterilization of women is a legitimate and proper procedure, but we must be careful in the selection of cases. I think we all agree that the state has a perfect right to sterilize epileptics and criminals, the insane and the idiotic, whether male or female. We can also say that patients who have undergone repeated cesarean section should be sterilized. When it comes to cases of chronic nephritis, I am not quite sure that we have a right to sterilize such women. In these days of commercial crazy surgery, it is well worth while to set a limit to what we are going to do in this particular field.

Dr. Herman E. Hayd, Buffalo: Dr. Hedges suggests an omniscience on the part of the surgeon that does not exist. For him to assume that such and such a case of diabetes, and such and such a case of chronic nephritis is going to terminate fatally is unscientific. It is too sweeping, and, moreover, that we should possess surgical qualifications which will enable us to carry these people through this surgical undertaking without a mortality is equally absurd and extravagant. I believe that sterilization would be justifiable in these cases of chronic nephritis and of diabetes, provided these women may die of some unrelieved condition, such as a perforating ulcer of the stomach, a duodenal ulcer, an acute gangrene of the gallbladder, or an acute appendicitis.

Dr. Gordon K. Dickinson, Jersey City, N. J.: I have never had the courage to sterilize women, except for narrow pelves, and when the children cannot be born except by repeated cesarean sections. If we feel the necessity of saving a woman from pregnancy; if, after carefully studying the woman as well as the condition, we think it is wise to sterilize her, we should do so, but not until we try other measures which are well known and which are not surgical.

Dr. Charles L. Bonifield, Cincinnati: Certain conditions have been mentioned which justify sterilization; but the essayist's enthusiasm has carried him beyond the sphere of a private physician. If the state makes laws to prohibit marriage, or to necessitate the sterilization of certain women, we shall, in obeying these laws, be considered good citizens. But my conscience will not permit making a law for myself as broad as the doctor has laid down. I do not believe it is within the province of the physician, in some of these conditions, to place a woman so that she cannot become pregnant. If she should not become pregnant, it is the physician's duty to tell her and her husband so, and then they must decide what shall be done.

Dr. Robert T. Morris, New York: Dr. Hedges' paper is all right, but it requires elaboration. I would not think of sterilizing a woman for diabetes until I had ascertained the cause of her diabetes. We must remember that diabetes is not a disease but a symptom. As to tuberculosis, more than 50 per cent. of the people in all the civilized world have had evidences of this disease of one sort or another during some stage of their lives. In tuberculosis of the lungs, advancing and uncontrolled, I would say, sterilize the woman.

Dr. William E. Darnall, Atlantic City, N. J.: I do not believe that Dr. Hedges meant to say that sterilization should be performed in every one of the cases he enumerated, but I do believe there are patients in each one of these classes that should be sterilized. After a thorough study of the case of the woman and her tendencies, there may be found in each class some women who need to be sterilized.

Dr. E. W. Hedges, Plainfield, N. J.: If a woman presented anasarca, rapid heart, dyspnea and extreme symptoms of poisoning from chronic nephritis, I would not hesitate to sterilize her. When the textbooks tell us that 30 per cent. or more of mothers that become pregnant under conditions of chronic nephritis die, we are warranted in advocating sterilization of such women to save life.

Operation for the Cure of Complete Perineal Laceration

Dr. Edward J. Ill, Newark, N. J.: I make an H-shaped incision which extends from just inside Bartholin's duct down to the outer side of and behind the ends of the sphincter. The horizontal bar of the H starts above the end of the sphincter and continues across the vaginorectal junction. The anterior and posterior flaps are elevated, particular care being exercised to denude the ends of the sphincter. Submucous suture of the rectum by a double line of fine plain catgut is done. The catgut never touches the rectal mucous membrane. Deep silver wire perineal sutures are used, and the vagina is sutured with plain catgut.

Prolapse of the Uterus

Dr. Charles L. Bonifield, Cincinnati: Recognizing how and why prolapse has occurred, the rational treatment is to decrease the weight of the uterus, replace it in its normal location and attitude and relieve it of all its abnormal burdens. The weight of the uterus may be decreased by rest in bed, curettage and amputation of the cervix, which is always hypertrophied in these cases. The uterus may be held in its normal place and attitude by a Gilliam operation, or, if the patient has passed the child-bearing period, by a ventral suspension, which is a little more easily and quickly done. The uterus may be relieved of other burdens by the proper operations on the posterior vaginal wall and perineum and the anterior vaginal wall. Some surgeons do not like to take the time necessary to perform the surgical steps that result in an anatomic and physiologic cure of these cases. If the operator is determined to be very deliberate about his work, there is no reason why the operation should not be divided into two steps. It is better to restore a woman to her normal condition by an operation that requires time and care for its execution, than to mutilate her with one that seems more brilliant and can be done in less time.

Operative Treatment of Procidentia

Dr. Arthur T. Jones, Providence, R. I.: In the selection of an operation we must take into consideration the age of the patient, whether the woman is still in the child-bearing period and capable of becoming pregnant. No operation which does not permit of pregnancy and the patient carrying her child to term should be performed on a woman still within the child-bearing age. If it is necessary to remove the uterus, the vagina and cervical stump may be suspended so as to prevent further prolapse of the vagina and cervix. No operation for procidentia is satisfactory which does not include the proper vaginal and perineal work, as support is needed below in conjunction with any suspension or interposition operation. In women still within the child-bearing period, without complications or disease of the appendages, the Alexander operation, in connection with proper vaginal work, has proved very satisfactory in my hands. In women past the menopause, the interposition operation of Watkins-Wertheim has given greater satisfaction than any other method.

Preeclamptic Cesarean Section

Dr. John Wilson Poucher, Poughkeepsie, N. Y.: When a patient at or approaching term, in spite of all means of elimination, shows by nervousness, sleeplessness, severe headaches, high blood pressure, edema and excessive albuminuria that convulsions are imminent, she should be delivered at once by the method that will cause the least delay, produce the least shock, and give both mother and child the best chance for recovery. Since 1914 I have done seven preeclamptic cesarean sections. All seven mothers and eight children survived. Two were operated on after labor had begun, five before the beginning of labor. Two suffered postpartum convulsions, two having two convulsions, the other one convulsion, which were easily controlled.

14 *Id. Influence of Experimental Ulcers *of* Stomach and Duodenum *on Hunger* Contractions of Empty Stomach. *J.* R. Dundon, *Chicago.*—p. 234.

15 Genesis and Inhibition of Extensor Rigidity. S. Cobb, A. A. Bailey and P. R. Holtz, Baltimore.—p. 239.

7. Effect of Blood Flow on Liberation of Epinephrin.—It it shown by Stewart and Rogoff that within the limits of error *of the method used for the assay* (rabbit intestine and uterus segments) the concentration of epinephrin in the suprarenal vein blood collected from a cava pocket varies in *different samples from the same animal inversely* as the rate of blood flow through the glands during the period *of* collection, the rate of output of epinephrin per minute being constant under *the* experimental conditions for a considerable range of blood flow. The rule fails, of course, *when* the rate of blood flow is diminished below *the value* at which the *concentration* of epinephrin has reached the possible maximum. For this reason determinations of the rate of spontaneous liberation of epinephrin by assays *on* drawn suprarenal vein blood should be made on samples obtained with a rate of flow well above this limiting value.

8. **Effect of Calcium on Vagus Inhibition.**—Brine found that calcium-free solutions or solutions with a very small percentage of calcium do not interfere with vagus activity, contrary to results previously reported.

9. **Action of Epinephrin on Blood.**—Blood from the suprarenal vein of a dog, diluted to 10 per cent., 6.6 per cent. and 5 per cent. with normal saline, Tyrode's solution or dog's serum in which the dissolved oxygen is kept at a minimum, shows spectroscopically intensification of the oxyhemoglobin bands. Spectra obtained when epinephrin (base) is added to diluted venous blood are identical with those given by suprarenal vein blood similarly diluted. Venous blood to which epinephrin is added or suprarenal vein blood forming an increase of oxyhemoglobin when diluted show in from one to five hours, if the oxygen dissolved in the dilution medium be minimal, a transformation of the oxyhemoglobin into urobilin. Addition of epinephrin to diluted human venous blood causes an increase in the intensity of the oxyhemoglobin absorption bands. The possible physiologic significance of these reactions for the heart and lungs in the living organism is discussed by Menten.

10. **Carbon Dioxid Acidosis.**—The definition that acidosis is a condition in which there is an actual increase in the H-ion concentration of the blood, Scott says, is the only one that is sufficiently comprehensive.

12. **Effect of Epinephrin on Blood Flow in Thyroid.**—Experiments made by Gunning showed that epinephrin in all dosages produces vasoconstriction in the thyroid gland. There is a slight tendency to overrecovery in the outflow, due supposedly to vascular fatigue. The threshold is lower than in any other organ so far studied. In no case was primary dilatation observed. The literature seems to support the apparent paradox that an increased secretory activity of the thyroid is accompanied by vasoconstriction.

13. **Hunger and Appetite in Fever.**—There is an absence of hunger contractions and a lowering of the stomach tonus during fever in dogs when the temperature reaches 103 F. and above; this being especially true in the temporary fevers. The temperature elevation itself is a factor in the depression of the stomach tonus and an inhibition of hunger contractions. The splanchnic nerves do not appear to be involved in the inhibition. The fever or the toxins appear to induce a lowering of vagus tone, and this leads to a cessation of the hunger contractions. But the authors do not believe that this will account for absence of hunger during a fever lasting ten to twenty days. Bacterial toxins, namely, B. paratyphoid toxin, B. prodigiosis, tetanus and diphtheria toxin, sodium nucleate, have no direct action on the contractions of stomach musculature, particularly of pyloric strips. Starvation does not induce fever in new-born pups.

14. **Experimental Ulcers and Gastric Hunger Contractions.**—In three out of four dogs with ulcers in the duodenum or the pyloric end of the stomach the motility of the empty stomach was greater than normal. But this augmentation of the gastric hunger contractions was not sufficiently marked to account for the excessively painful character of these contractions in ulcer patients. It is therefore probable, says Dundon, that the hunger pains in gastric and duodenal ulcers in man are not due to excessive hunger contractions, but to hyperexcitability of the sensory nerves in the stomach wall, as suggested by Carlson. The effects of gastro-enterostomy on the gastric hunger contractions are variable, with a tendency to depression. The hypomotility, when present, may be due to valve-like action of the intestine opposite the stoma causing retention of the food in the duodenum and hence a reflex inhibition of the stomach from the duodenum as well as regurgitation through the stoma.

25 *Gold Therapy of Tuberculosis. L. M. DeWitt, Chicago.—p. 424.

25. **Gold Therapy of Tuberculosis.**—DeWitt's work on the gold therapy of tuberculosis has extended over two years and was carried on practically exclusively on tuberculous guinea-pigs. She began her experiments with the ordinary gold cyanids, $AuK(CN)_2$, $Au(CN)_3$ and $AuCN$. Her results show that life was not prolonged and the disease was not checked as compared with the control animals. The average duration of the disease in the untreated controls was considerably longer than in the treated animals. The extent of the disease in the two set of animals was also about the same. The gold was administered by intracardiac, intramuscular and subcutaneous injections at intervals, with feeding of the gold salt on all days when there was no injection. The subcutaneous injections caused considerable necrosis and the intracardiac were by no means without danger; and the treatment apparently had no beneficial effect on the progress of the disease.

26. **Experience with Meningitis.**—This article contains too much meat to be abstracted in its entirety, but the section on treatment may be summarized as follows: Various methods of treating the acute stage of poliomyelitis were tried during the summer of 1916, without very decisive results. The intraspinal injection of epinephrin was endorsed by only a few after it had been used for a short time. The injection of human immune serum was quite extensively tried. Injecting a foreign substance into the slightly inflamed meninges sets up in most instance an acute aseptic meningitis, as is shown both by changes in the spinal fluid, and clinically by an increased temperature, headache, vomiting and rigidity of the neck. It seems possible that this increased inflammatory reaction may tend to accentuate the inflammatory process already existing in the subjacent substance of the brain and cord. That this reaction may be harmful was further borne out by the results of animal inoculation, the treated animals showing a higher mortality and a more rapid death than the controls, in the majority of cases. While great improvement seemed to follow the administration of serum in certain cases, equally great improvement occurred with no serum in at least an equal number of cases. In view of these considerations the physicians of the meningitis division of the New York Department of Health feel that the best treatment of early cases is complete rest, with lumbar puncture for the relief of pressure symptoms, in addition, of course, to general symptomatic and hygienic treatment.

35. **Chronic Valvular Heart Disease in Pregnancy.**—The following conclusions are drawn by Kellogg from a study of cases of chronic valvular heart disease in pregnancy and labor. Of pregnant women, 1 to 2 per cent. have chronic endocarditis. Under prenatal care, 15 to 20 per cent. have shown some decompensation, half of these 1 degree decompensation, half 2 degrees decompensation. Cases with stenosis of the mitral valve, with or without insufficiency, are far likelier to decompensate in pregnancy than cases with simple insufficiency. The maternal mortality of chronic valvular disease in pregnancy is 2 per cent. The maternal mortality of cases showing 2 degrees decompensation, requiring induction and 2 degrees decompensation in labor, is 45 per cent. Mitral stenosis is almost always present in fatal cases. Fetal mortality runs from 10 per cent., in a series including all cases, to 40 per cent. in cases with 2 degrees decompensation. Chronic valvular heart disease complicating pregnancy is, in view of these figures, potention of their lives so that they do not again decompensate, and so that they will stand any appropriate method of delivery at term. Many chronic valvular heart cases compensated and with only slight degrees of decompensation and some with 2 degrees decompensation will safely deliver themselves if allowed to. Though this fact is undeniably true, theoretically, and with what data we have at hand, it should not be allowed. Normal delivery and accouchement forcé have no place in the treatment of chronic valvular heart cases in pregnancy or labor. It is not justifiable to attempt to carry a woman who is decompensated to term for the sake of her baby unless she reacts favorably to treatment almost immediately, especially as the fetal mortality in these cases is so high that one overrisks the mother for the sake of a problematic child.

40. **Roentgenographic Characteristics of Shrapnel Balls Compared with Bullets and Other Foreign Bodies.**—In about a year at a hospital in France where Pirie was in charge of the roentgen-ray department, 241 plates of shrapnel balls and 242 plates of bullets were made. He says that shrapnel balls may be found entire without any deformity, and every stage of deformity may be met with till an appearance is obtained as if the ball had exploded into small particles. There is one entrance wound only, if the ball is entire, and the wound is rather characteristic. If the ball has struck an external object before striking the patient, it may break into two or more pieces, and the wounds of entrance will then be multiple. When the ball passes into the body it remains there. A shrapnel ball rarely passes through the body and comes out at the other side the way a bullet does. When a shrapnel ball meets a bone it becomes deformed according to the resistance offered by the bone, and some of the lead is left behind, on or near the bone. There were two bones only which Pirie found a shrapnel ball cannot penetrate, namely, the femur in its shaft and the vault of the skull.

The contrast between the damage done by a bullet and that done by a shrapnel ball is very marked when a direct hit is made on the femur or on the skull. A bullet hitting the femur splinters the bone, as it does a glass bottle. At the same time, the bullet breaks into pieces, and its fragments and those of the femur are scattered through the limb, or blown out through the skin as if an explosion had taken place. When a bullet goes through cancellous bone like the head of the femur it may punch a clean hole and cause very little fracturing, but one of the worst fractures is caused when it hits the dense bone of the shaft near its junction with the cancellous bone. In this case the splinters of dense bone are driven into and split up the cancellous bone.

41. **Radical Cure of Inguinal Hernia.**—Starr calls attention to a method of attack on a hernia from within the abdomen when one is operating for other conditions and it is desired to repair a hernia at the one sitting. A pair of curved forceps may be introduced through the internal ring into the sac and the wall of the sac grasped and gradually pulled up into the abdomen until the fundus of the sac becomes completely invaginated. Then the suture with which it is intended to close the abdomen is passed through the neck of the sac and tied to the parietal peritoneum. The suture is then continued along the sac, suturing it to the parietal peritoneum, so that by the time the sac is fully dealt with the suture has reached the cut edges of the abdominal incision and is then carried along, closing the peritoneum. This makes a perfectly satisfactory cure of the hernia, is easily and quickly done, besides saving a second incision. Starr has records of seven cases that have stood the test for two years and more.

45. **Western Provinces are Trying to Provide Hospital Accommodation for Their Rural Sick.**—The question of hospital accommodation and nursing attention for the prairie sick has been the subject of legislation in the twin provinces of Saskatchewan and Alberta. Provision has been made whereby groups of rural and urban municipalities may cooperate in the erection and maintenance of hospitals to serve their people. Each municipality concerned has the power to levy a rate, not exceeding two mills on the dollar, on all assessable property within its borders, for hospital purposes. The managing board is composed of representatives appointed by the councils of the cooperating municipalities, but not necessarily members thereof, and is a body corporate, with powers governing such bodies. The feature which has commended itself more especially to the prairie people in connection with the establishment of these rural hospitals is the immense benefit which they are calculated to confer in maternity cases and emergency sickness.

Broadly speaking, four rural municipalities require a hospital providing accommodation for twenty-five beds, besides quarters for the working staff. The cost of such an institution for building and equipment is estimated at from $1,200 to $1,500 per bed capacity, or between $35,000 and $40,000. Raised by debentures spread over a term of thiry years, and borne by the municipalities in proportion to their assessable value, this capital expenditure represents a very modest increase to the homesteader's taxes. Regarding maintenance, careful investigation suggests that from fifty-five to seventy patients might be expected from each rural municipality, with an average stay in the hospital of fourteen days, at an estimated cost of $2 a day per patient. This would mean that for capital cost, on thirty year debentures, bearing interest at 6 per cent., each rural municipality would have to provide less than $1,000 per annum, while for maintenance, should the maximum estimate be realized and seventy patients receive treatment for fourteen days per patient, $1,960 would be required, or a total cost to each municipality of something like $2,960. As the Saskatchewan government, however, makes a grant of 50 cents per day for every patient receiving treatment in the hospital, $490 would be received from this source, leaving the rural municipality to provide less than $2,500 to meet its debentures, establish a depreciation fund, and pay the hospital fees of any of its ratepayers or their dependents in the province of Saskatchewan. A 1 mill rate will yield at least $2,750, or $250 in excess of the total amount required as the proportion from any one municipality to finance the whole undertaking of building, equipping and providing free hospital accommodation, and the best of skilled nursing attention for every ratepayer and his dependents who may require it, and that without involving any sense of obligation, as the system is one of cooperative municipal insurance.

79 *Rôle of Hepatic Tissues in Acute Anaphylactic Reaction. W. H. Manwaring and H. E. Crowe, San Francisco.—p. 517.

74. **Intracutaneous Reaction in Diarrhea.**—In a series of thirty-three cases the organism of the infectious diarrhea group was isolated in 55 per cent. of the cases. Agglutinins for the dysentery group were found in 12 per cent. of the cases which were found to be negative from the bacteriologic examination and a characteristic smear, as stained by Gram's method, with a typical history in 25 per cent. of the other cases. The intracutaneous reaction, on the other hand, showed 100 per cent. negative results in the control cases. In cases with history of infectious diarrhea positive reactions were obtained in 85 per cent. of the cases.

77. **Vascular Lesions in Protein Intoxication.**—This paper is a continuation of the work previously reported, with especial reference to the occurrence of vascular lesions in various organs. The materials used and methods employed were the same as those previously described, the object desired being to give each animal as many anaphylactic shocks as possible during the course of the experiment, using egg-white and beef serum. Boughton found that repeated injections of foreign proteins in sensitized guinea-pigs produce lesions of the smaller arteries of liver, kidney, spleen and heart, characterized by degeneration and regeneration of endothelium, edema and fissuring of intima and media, and sometimes splitting of the internal elastic lamina. These lesions are interpreted as being subacute rather than chronic. These lesions are rarely found in the larger arteries, and not at all in the aorta. They are practically absent from veins and capillaries. These lesions occur in 100 per cent. of the livers, 100 per cent. of the spleens, 66 per cent. of the kidneys, and 66 per cent. of the hearts, and were most severe in the livers and least severe in the hearts. The lesions were most severe in animals dying or killed soon after the last injection, and were less frequent and severe in animals killed several weeks after the last injection. Perivascular infiltration was observed in 60 per cent. of the animals, though never severe, but was not found in animals killed more than five weeks after the last injection.

78. **Foreign Protein in Anaphylactic Reaction.**—The validity or nonvalidity of the principal theories concerning the nature of the acute anaphylactic reaction was tested by the authors. Perfusions of isolated organs and tissues with dilute foreign proteins furnished no evidence of a measurable destruction of the foreign protein by the blood serum, nor of an appreciable destruction or binding of the foreign protein by the fixed tissues during the acute anaphylactic reaction.

79. **Hepatic Tissues in Anaphylactic Reaction.**—It was found by Manwaring and Crowe that the detoxicating action of the anaphylactic liver is not due solely to the presence of anaphylactic humoral elements. There is evidently an acquired detoxicating function of the fixed liver cells. The detoxicating action is not due to a removal or destruction of the foreign protein in the perfusion fluid. The liver of a normal guinea-pig, repeatedly perfused with a mixture of foreign protein and defibrinated normal or anaphylactic blood, produced little or no change in the toxicity of the perfusion mixture on subsequent tests with isolated anaphylactic lungs. The liver of an anaphylactic guinea-pig, similarly perfused, usually rendered the perfusion fluid almost completely nontoxic for these lungs. Evidence points to the explosive formation or liberation of vasodilator and bronchodilator substances by the sensitized liver cells.

83 *Method for Standardization of Thyroid Preparations. J. M. Rogoff, Cleveland.—p. 199.
84 *Influence of Oxygen on Inflammatory Reactions. S. Amberg, A. S. Loevenhart and W. B. McClure, Madison, Wis.—p. 209.

80. **Effect of Caffein on Respiration.**—No significant change was found by Grabfield and Means in the rate of reaction to carbon dioxid as a result of taking various doses (small and large) of caffein alkaloid, by mouth, in two normal human subjects.

81. **Certain Antagonists of Pilocarpin.**—The net result of Ransom's experiments is to make it clear that the chronotrope and inotrope actions of pilocarpin are fundamentally distinct. They are both vagal effects but different groups of vagal fibers are concerned in their production and hence one action can be antagonized while the other remains intact. Atropin paralyses vagal endings and hence entirely antagonizes the heart actions of pilocarpin. Strontium, digitalis, agaricin and saponin, which, without affecting the vagus, have a positive inotrope action on the frog's heart, antagonize the negative inotrope action of pilocarpin but leave the negative chronotrope effect unimpaired. Epinephrin and caffein antagonize both the actions of pilocarpin, not because they affect either of the two sets of vagal fibers, but because they produce effects the reverse of those which stimulation of the two vagal groups brings about.

82. **Pharmacology of Ipecac Alkaloids.**—The experiments reported by the authors demonstrated that in cats the emetic dose of emetin hydrochlorid is approximately twice that of cephaelin hydrochlorid, and that the higher homologues of this series decrease in emetic power very much in the same ratio as they do in toxicity, as reported in a previous paper. Furthermore, it has been shown that the hydrochlorid, hydrobromid and hydro-iodid of emetin vary only slightly in their emetic power, but that the hydro-iodid of cephaelin iso-amyl ether, due to its relative insolubility, is about one half as emetic as the hydrobromid or hydrochlorid of cephaelin iso-amyl ether and only one sixth as emetic as emetin hydrochlorid. When tested on the conjunctiva of rabbits, emetin and cephaelin are the most irritant of this series and cephaelin iso-amyl ether is least irritating. When injected intramuscularly in rabbits cephaelin iso-amyl ether is the most irritant while the difference between the other less irritant members of the series is not marked. Cephaelin propyl ether phosphate gives no more than a slight local reaction when injected hypodermatically into persons, while cephaelin iso-amyl ether salts cause severe pain, soreness and local inflammation.

83. **Standardization of Thyroid Preparations.**—A method is described by Rogoff in which the specific action of thyroid on tadpoles is used to assay the physiologic value of commercial thyroid preparations. Of seven products purchased in retail drug stores, two indicated about 20 per cent. more activity than a standard preparation, two were equal in value to the standard, one somewhat more than 50 per cent. of the standard, one less than 50 per cent., and one was a practically worthless preparation—being only about 10 to 20 per cent. of the value of the standard.

84. **Influence of Oxygen on Inflammatory Reactions.**—Amberg and his associates found that the intravenous injection of the sodium salts of o-iodoso-benzoic acid and o-iodoxy-benzoic acid inhibits the mustard oil reaction of the rabbit conjunctiva as well as that of the skin. No other visible changes in the organism accompany this inhibiting action. Other substances containing chemically active oxygen, such as the sodium salts of diphthalic peroxid, iodic and periodic-acids have an inhibiting action on the mustard oil inflammation. It seems reasonable to ascribe the inhibiting action of these substances to the chemically active oxygen. Exposure of rabbits to atmospheres with reduced partial pressure of oxygen did not have any marked effect on the intensity of the intracutaneous mustard oil reaction. Intravenous injections of sodium cyanogen seem capable of intensifying the conjunctival mustard oil reaction under proper conditions. Within certain limits an influence on tissue oxidations seems to determine an inhibition or intensification of the response to inflammatory stimuli. It seems possible to alter the character of the conjunctival mustard oil reaction by intravenous injections of substances, such as sodium hypochlorite. Irritation produced elsewhere in the organism, as by intraperitoneal injections of kaolin, animal charcoal, mustard oil, may exercise an inhibiting influence on the conjunctival mustard oil reaction of the rabbit.

130 *Case of Atypical Thyroid Disease, Formes Fruste. M. G. Sturgis, Seattle.—p. 281.

121. **Syncytioma Malignum.**—Anderson reports a case from which it would not appear that it is always necessary to do a complete hysterectomy in cases of malignant syncytioma. He believes that most authorities are too radical and that each case must be handled according to the conditions that exist at the time of operation. From the fact that metastasis takes place through the blood, it would seem that, if metastasis had occurred at all, a complete hysterectomy would give little more chance of permanent cure than a resection of the macroscopic growth.

123. **Smallpox in Utero.**—A woman, pregnant about three months, was sleeping in the same bed with her husband who was found to have smallpox. She was immediately removed to another room and she and her two children and a man and woman who were taking care of the family were successfully vaccinated. The woman had a typical reaction to the vaccine virus. The quarantine was raised in six weeks. One month afterward Rothwell was called to see her. On examination he could find no signs of life in the fetus and the os uteri was dilated about the size of a quarter. The vagina was aseptically packed with gauze and at 6 o'clock next morning a six or six and a half months mummified fetus was expelled. Life must have been extinct for some time, as the abdomen was discolored and distended, and the abdominal muscles and integument were very thin and fragile. What was most noticeable, however, was the presence of round, yellow, slightly pitted scars about the size of the end of a lead pencil, distributed over the whole surface of the body, where the scabs had become detached in utero. Also the vesicles and pustules that invariably accompany a severe case of variola vera were present. The mother had never a sign of a papule, vesicle or pustule but she has a normal vaccination scar.

130. **Atypical Thyroid Disease.**—Sturgis' case presents the unusual spectacle of the symptoms of a preexisting hyperthyroidism overlapping and overshadowing a well developed hypothyroidism, and completely dominating the clinical picture. Compared with them, those arising from hyposecretion seemed almost inconsequential, and yet the first examination disclosed the fact that the gland was almost entirely atrophied and had ceased to functionate. That the symptoms of hyperthyroidism had not only persisted but had even increased seemed to warrant the conclusion that the thyroid was only partly at fault. The blood pressure was amazing. For 125 mm. the sounds fairly snapped and they were audible for 200 mm.

138 Case of Snake Bite, Treatment. A. S. Daggette, Pittsburgh.—p. 838.

133. **Treatment of Rheumatoid Arthritis.**—The facts emphasized by Pemberton are, first, that in rheumatoid arthritis it is necessary to reduce the carbohydrates by an important amount, varying with each case; second, that it is necessary to reduce the proteins considerably, but relatively not so much; and third, that, although the fats cannot be handled with impunity, they may be used with caution to increase the caloric value of the ingested food and meet in some degree the loss of weight. Experiments have shown that some patients were carried through to convalescence with an actual gain of weight by using fat in quantities sufficient to equal or exceed the caloric deficit.

134. **Blood Pressure from Standpoint of Clinician.**—Dever urges that a knowledge of blood pressure is an aid in diagnosis, especially in the cardiovascular-renal diseases. An excellent idea of the functional capacity of the myocardium may be obtained and in acute and chronic disease evidence of weakening of the heart thus may be obtained before other signs of circulatory weakness is evident. The blood pressure is a guide in the treatment of certain diseases, notably chronic renal insufficiency as found in chronic interstitial nephritis. The diastolic pressure should be recorded as well as the systolic pressure, as the latter alone is insufficient to reveal all that is to be ascertained by a study of the blood pressure.

7 *Some Results Obtained by Heiser's Treatment of Leprosy in Nigeria. H. S. Coghill.—p. 205.

1. **Periodicity of Microfilaria Nocturna.**—In the case cited by Yorke and Blacklock blood films made during the daytime were either negative or contained only an odd microfilaria,

whereas in those prepared at night microfilariae were found in considerable numbers. Thick dehemoglobinized films were stained with hematin, and the morphology of the parasite examined. The larvae were identified as those of *Filaria bancrofti.* A series of observations was made with the object of studying the periodicity of the microfilariae in the cutaneous blood. The number of larvae per cubic centimeter of cutaneous blood was estimated every two hours for a period of twenty-four hours, on two occasions. Furthermore, the number of larvae per cubic centimeter of venous blood (median basilic vein) was determined. It was found that obstruction to the passage of *Microfilaria bancrofti* through the cutaneous vessels occurs at all times of the day and night, but is at a minimum at the end of the period of bodily activity. Although this obstruction aids in the piling up of the larvae in the cutaneous vessels, it is in no way responsible for the nocturnal periodicity.

The nocturnal periodicity is primarily dependent on periodic variations in the arterial supply of larvae to the cutaneous vessels. By reversing the hours of sleep and activity, cutaneous immigration becomes diurnal instead of nocturnal. The change, however, takes place gradually; after the periods of sleep and activity had been reversed for four days the time of maximum concentration of the larvae in the cutaneous vessels had only been set back six hours (from midnight to 6 a. m.); when reversal of the hours of sleep and activity had lasted for eleven days the time of maximum cutaneous concentration had been changed from midnight to midday. The number of microfilariae, as judged from the maximum concentration in the cutaneous blood, remained at practically a constant level during the period of observation. The number of microfilariae present in 100 c.c. of urine varied greatly at different times during a twenty-four-hour period. These variations, which were irregular and gave no indication of either a nocturnal of diurnal periodicity, are explained on the assumption that the majority of the microfilariae escaped into the urine with the blood. Graphs depicting the number of larvae per cubic centimeter of urinary blood reveal the existence of a regular periodicity corresponding to that of the larvae in the cutaneous blood, with the difference that the time of maximum concentration was several hours later. The number of microfilariae in the renal and vesical vessels exhibits a nocturnal periodicity analogous to that in the cutaneous vessels.

2. **Quinin Bihydrochlorid in Treatment of Malaria.**—Single injections of quinin bihydrochlorid were given in eight cases of simple tertian malaria. In seven of these the amount of quinin injected was 15 grains, in the other, 10 grains. The results were similar in all cases. The temperature fell to normal in one to three days, and parasites disappeared from the cutaneous blood in two to five days. Six of the eight patients relapsed. Parasites reappeared in eight to fourteen days. Febrile paroxysms recurred on an average in fifteen days (minimum 10, maximum 20). Of the remaining two patients, one was given quinin orally on the fourth day, and the other died of cerebral hemorrhage of undetermined nature on the tenth day.

Multiple injections were given in thirteen cases, five in one case and six in twelve. The injections were given on Mondays, Wednesdays and Fridays. As a rule, 10 grains were given at each injection, but on a few occasions 15 grains. In one patient the treatment did not cause the disappearance of parasites from the blood, but the febrile paroxysms were controlled. In another case the temperature fell to normal after the first injection, parasites disappeared from the blood after the second injection, and there was no relapse for an observation period of two and a half months. In the remaining eleven cases the temperature fell to normal after one to three injections; the parasites disappeared from the blood after one to four injections. All of the eleven patients relapsed. Parasites reappeared in eight to eighteen days. Febrile paroxysms recurred on an average of eleven days.

Single injections were given in two cases of malignant tertian malaria: 15 grains in one case, 10 grains in the other. In neither did the treatment cause the parasites (trophozoites or gametes) to disappear from the blood. Multiple injections were given in five cases; four in one case, and six in four. The injections were given on Mondays, Wednesdays and Fridays; 10 grains on every occasion. In each case the treatment was administered during an apyrexial period. Speaking generally, the treatment did not cause the parasites (trophozoites or gametes) to disappear from the cutaneous blood. In a series of 127 injections, thrombosis occured in four patients. There was no other symptom worthy of note.

3. **Amylopsin and Trypsin in Treatment of Tertian Malaria.** —Intramuscular injections of amylopsin and trypsin proved to be of no value in the treatment of ten cases of acute simple tertian malaria. Some swelling and tenderness occurred at the site of injection. On this account, and because the paroxysms were not checked, the majority of the patients refused to have more than one or two injections.

4. **Quinin Alkaloid in Treatment of Tertian Malaria.**—The solution used by the authors for this purpose was made in the following way: 1 gm. of quinin alkaloid was dissolved in 1 c.c. of 90 per cent. alcohol, and the volume made up to 3 c.c. with sesame oil. By this means a clear viscid solution capable of being easily injected was obtained, 1 c.c. containing approximately 5 grains of the alkaloid. The injection brought about: (1) A cessation of febrile paroxysms. The temperature usually fell to normal within four days of the first injection. (2) Disappearance of parasites (trophozoites and gametes) from the cutaneous blood usually in one to two days. Thirty-one of the thirty-eight patients treated relapsed. Parasites reappeared on an average in eighteen days. Febrile paroxysms recurred on an average in twenty days. The remaining seven patients had not relapsed within an observation period of two months.

A comparison of these results with those recorded with the use of a very soluble salt of quinin, the bihydrochlorid, shows that the therapeutic action of the insoluble alkaloid is in no way inferior to that of the soluble salt. Subcutaneous injections of this solution resulted in sloughing. Intramuscular injections of 3 to 4 c.c. resulted in slight pain at the time of injection; in larger doses, 6 c.c., the immediate pain was more severe and pain recurred some twenty-four to forty-eight hours later. There was no abscess formation or other ill effect. For several days after injection a slight diffuse swelling was appreciable at the site of injection; this, however, disappeared entirely in the course of a few days.

5. **Occurrence of Intestinal Protozoa in Nondysenteric Cases.**—Of 200 nondysenteric patients in the hospital for various diseases 34.5 per cent. were found to be infected with various protozoa. *E. histolytica* was discovered in fifteen cases (7.5 per cent.). One hundred cases were malaria and among these six infections with *E. histolytica* were detected. There were forty-two cases with a history of dysentery and 158 cases with no history of dysentery. Of the former 7.1 per cent. were found positive to *E. histolytica,* and of the latter 7.6 per cent. Of 142 patients who had been to tropical or subtropical regions, 11, or 7.7 per cent., were found infected with *E. histolytica.* The remaining fifty-eight patients had been to France only, and four, or 6.9 per cent., were discovered to be infected with this parasite. The great majority of the cases (123) had only two examinations each.

7. **Heiser's Treatment of Leprosy.**—The method of treatment of leprosy described by Heiser has been tried by Coghill with some of the inmates of the Yaba Leper Asylum. The treatment was begun in May, 1916, so that it is as yet too soon to make a complete report, more particularly as all the patients are old standing cases. The oil mixture used was that recommended by Heiser: chaulmoogra oil, 60 c.c.; camphorated oil, 60 c.c., and resorcin, 4 grains. The mixture was sterilized by boiling, and 2 c.c. injected intramuscularly into the buttock, were given as an initial dose. After the lapse of one week, 3 c.c. were given, and this dose was increased by 1 c.c. per week until 8 c.c. were being administered. Beyond this amount some discomfort was complained of, so that the procedure finally adopted was to inject 6 c.c. twice a week. This dose was well tolerated and every case responded to treatment. The most rapid and obvious effect was the healing of ulcers, many of them large and deep, and

of many years' duration. Softening, then absorption of the nodules, fading of the maculae and the return of sensation were also observable, even to the patients themselves.

10. **Sphere of Arthroplasty in Treatment of Ankylosis.**—While arthroplasty may be brilliantly successful in joints ankylosed by purely traumatic lesions, Thomson says, it is liable to fail in points ankylosed as a result of bacterial infection. The two great causes of failure are found to be (1) either a recrudescence of the original infection, that is, tuberculosis and dormant infections of gunshot injuries, interfering with the formation of the false joint, or (2) an increased activity of the bone forming tissues leading to a return of the ankylosis.

16 *Pathology and Treatment of Barcoo Rot (Veld Sore). C. J. Martin.—p. 118.
17 Strangulation of Pylorus. C. Friend.—p. 120.

14. **Surgical Treatment of Ulcer of Stomach and Duodenum.**—The following deductions are drawn by Devine from his experience with thirty-eight cases. Gastro-enterostomy only for a lesser curvature ulcer may result in a failure or cure. Wide resections of an ulcer almost to greater curvature unassociated with pyloric stenosis resulted in all cases in a permanent cure. Postoperative distress was noticeably absent, and no gastro-enterostomy was necessary. Cases of postpyloric or prepyloric ulcers with marked stenosis did well with simple gastro-enterostomy. The autoplastic rectus sheath graft with gastro-enterostomy can be used with success in some cases of prepyloric and postpyloric ulcer in cases in which there is no stenosis, and especially in which there is a tendency to bleed. Stomach operations lend themselves to stage operations, and often this is the surest way for a successful termination of the surgical treatment. The surgical treatment should fit exactly the set of surgical pathologic conditions present, and the surgeon cannot have all this knowledge without a careful and thoughtful preoperative roentgen ray and clinical examination.

16. **Treatment of Barcoo Rot (Veld Sore).**—This disease is characterized by spreading superficial ulcers on the backs of the hands, extensor surface of the forearms and, to a less extent, on the dorsa of the feet and on the shins. The ulceration resembles that met with among bushmen in the backblocks of Australia (during the dry season), and is known locally as "Barcoo rot." The first sign is usually a bleb or blister containing thin, watery pus and surrounded by an area of slightly inflamed skin. The blister may be the size of a sixpense, or even larger, but before it reaches this size it is generally broken. The denuded surface shows little tendency to heal, but slowly extends at its margins, at the same time deepening until there are no more epithelial structures left. The ulcer, however, remains shallow, and it is unusual for the fibrous layer of the skin to be destroyed, unless it becomes infected with virulent staphylococci. The glands are not inflamed unless secondary infection occurs, and there are no constitutional symptoms. When healing has occurred, areas of glossy skin, more or less denuded of hairs and sweat glands, are left. Cicatrization does not occur unless the true skin is destroyed. Infection of fresh areas of skin in the neighborhood is usual, so that the patient has several ulcers of different ages. The disease in its minor forms is extremely annoying, and when the ulcers have become large, incapacitating. In hospital the ulcers generally heal up slowly under any sort of wet antiseptic dressing, but are very difficult to deal with in the field. Acting on the idea that infection of the hair follicles is largely responsible for the continuance of the ulcerative process, Martin removed the hair or hairs traversing the early blebs from the secondary infection, and found that these healed straight away. Next, working on the principle employed to restrict a bush fire, by burning an area in front of it, he attacked the larger ulcers, removing the hairs from their base, and around their margins and was pleased to find that the ulcerative process was stayed, and healing commenced at once.

18. **The Declining Birth Rate.**—This is one of the reports made by a committee appointed by the Académie de médecine to suggest measures to arrest the depopulation of France. Stress is laid on the principle of financial aid to the child up to the appearance of the twentieth tooth. Richet declares that France is dying unless heroic measures are taken. It is sound finance, he reiterates, to pay out possibly $400 for a little human being, who in the course of a few years will be earning an income of at least that every year. The state, society and the nation will all be the gainers financially.

19. **Child Welfare Work at Havre During the War.**—This report from the Havre board of health emphasizes that the birth rate has declined and the infant death rate risen during the war, principally from the mothers being obliged to leave their infants to work in the factories. Factory work is fatiguing for women, especially for nursing mothers. The help as now given has too much the aspect of charity. The mothers with dirty houses are looked after better than the self-respecting who are too proud to appeal for aid. The suggested remedy is that the financial aid should be given to all the nursing mothers alike, irrespective of their pecuniary condition. This would insure it to all who need it and would stop breeding professional beggars.

20. **Walling Off the Pelvis.**—Chaput describes the various methods with which he walls off the pelvis from the abdominal cavity after operations, or walls off one part from another, in both women and men. This allows the pus accumulating in the pelvis to be drained into the vagina, or rectum in man, after pushing up the small intestine and omentum out of the way and interposing a solid barrier against their sliding down again. The barrier can be total, transverse or vertical. He fastens the sigmoid colon to the superior strait and to the suprapubic peritoneum. This transforms the pelvis into a single cavity with smooth walls, with no crevices to retain pus, easy to drain and to disinfect. The thickness and the high position of the colon roof practically guarantees against propagation of infection upward to the abdomen.

23 *Comparative Resistance of Paratyphoid B Bacillus and Colon Bacillus in Drinking Water. G. Dauménzon.—p. 146.
24 *Syphilis and Masculinity. Girauld and Tissier.—p. 148.

22. **The Declining Birth Rate.**—Pinard presents the report of the committee which has been studying means to remedy the depopulation of France. It fills twenty-six pages, but no vote was taken. Among the principles advocated is that families which have no or few children must be made to aid those that have many. Also that the state should feel that it owes a debt to the woman who bears a child. Also that birth control measures are injurious for the woman as well as for the nation, and that the state should forbid and repress the birth control propaganda as a growing danger.

23. **Survival of Paratyphoid B Bacilli in Drinking Water.**—Daumézon reports that both the colon bacillus and the paratyphoid B long resist the antagonism of other germs in water when sheltered from the light by turbidity of the water. The paratyphoid B seems less resistant than the colon bacillus, but still it seems able to pass still viable through the filtering and other media that do not arrest the colon bacillus.

24. **Syphilis and Masculinity.**—Girauld states that in his service during a recent period 201 syphilitic women were delivered of 119 boys and eighty-two girls. Of the sixty-four living and apparently healthy children, forty-three were boys and only twenty-one girls.

32 Nongonorrheal Urethritis with Epididymitis, Caused by Pseudodiphtheria Bacilli. L. Ramond, and others.—p. 797.
33 *Meningeal Hemorrhage in Soldiers on Active Service. P. Nobécourt.—p. 802.

25. **Hemoglobinuria in Macedonian Malaria.**—Delille and his co-workers state that the tropical character of the malaria contracted by the French troops in Macedonia is evidenced particularly by the relative frequency of hemoglobinuria. The mortality was high, nearly 30 per cent. The malaria was usually of long standing, six months or more, and cold weather seemed to be a factor in its appearance. The findings indicate massive destruction of blood corpuscles, probably in the blood stream, as the first phase. It may be accompanied by hemorrhages from the mucosa. The hemoglobin thus liberated is transformed into bile pigments, the excess passing off through the kidneys. The hemoglobin may be in such quantities that it clogs the kidneys and the patient may succumb to anuria. In the more fortunate cases, the urine washes out the hemoglobin plugs. There was no death from anemia, and the corpuscles regenerated extremely rapidly.

26. **Emetin for Suppuration in the Liver.**—The emetin reduces the pain and fever in less than forty-eight hours whether the hepatitis is in an incipient phase or an abscess has formed. There may be no history of dysentery in the antecedents or the patient has forgotten it, but the intestines never forget it. Necropsy in fatal cases of liver abscess may reveal lesions suggesting chronic amebic dysentery though they failed to induce appreciable symptoms.

27. **Relapsing Fever in Macedonia.**—There was only one death among the fifty cases under observation. The onset was stormy, the liver always involved, with more or less jaundice in 90 per cent. of the cases. Lively headache and a suggestion of the Kernig sign and lymphocytosis were common. A second relapse occurred only in 10 per cent. and it was brief. The disease is essentially mild; only two deaths were known, both occurring with symptoms of acute suprarenal insufficiency, and a retrospective diagnosis of Addison's disease was manifest.

28. **Cancer and Trauma.**—Moreau describes an epithelioma developing in the parotid gland in a colonial of 42. He had been struck in this region in 1914 by a fragment of a shell but there was no superficial wound or fracture. There had never been any previous glandular trouble in the neck, but the man had a history of malaria, typhoid and a liver abscess. The cancer recurred after extirpation and radiotherapy.

30. **Paratyphoid B from Meat Poisoning.**—The small epidemic was traced to insufficiently cooked ham. The bacilli were found in the ham but they were also found on the hands of one of the cooks who proved to be a carrier.

31. **Mixed Infection in Meningitis.**—Netter and Salanier now have a record of twenty-two cases of meningococcus meningitis in which pneumococci were found also in the spinal fluid. This sustains their previous plea for combined antiserum treatment against both these germs.

33. **Meningeal Hemorrhages in Soldiers.**—Nobécourt remarks that meningeal hemorrhage is rather common in soldiers, as he has encountered it in three cases out of a total series of 2,660 patients in the contagious disease hospital in his charge not far from the front. Meningitis formed 8.3 per cent. of the total series. No cause for the hemorrhage was found in the two cases. In one of these, after a few days of headache, convulsions developed with aphasia and strabismus, and progressive flaccid paralysis followed. The onset was more insidious in the other case, with symptoms revealing tuberculous meningitis, fatal in a few days. In the third case the onset was sudden coma, the neck and legs stiff, with death in sixteen hours. Lumbar puncture disclosed meningeal hemorrhage in each case. The hemorrhage was profuse in the meninges and ventricle, as also in lungs and spleen, with intense congestion of kidneys and suprarenals, but no cause for this could be discovered, no inflammatory lesions, and the extravasated reds were of normal shape.

August, CXXVI, No. 8, pp. 349-396

34 *Mercurial Stomatitis; Pathogenesis, Prophylaxis and Treatment. M. Favre.—p. 349.
35 *Castor Oil as Lubricant for Wounds and Dressings. (L'huile de ricin.) L. Revillet.—p. 355.
36 *War Enteritis. A. Mollière.—p. 357.

34. **Mercurial Stomatitis, Treatment and Prophylaxis.**—Favre's extensive experience has demonstrated, he says, that the stomatitis which develops under mercurial treatment is identical in every respect with Vincent's ulceromembranous stomatitis, and treatment and prophylaxis should be the same for both. Vincent's spirillum is inevitably present, and if this spirillum is exterminated, the affection rapidly subsides, even with mixed infection. The mercury being taken merely induces local congestion and irritates the vessels, activating the spirilla already in the mouth, just as decayed teeth, deposits of tartar or the eruption of a wisdom tooth are liable to bring on Vincent's angina. It may exist in an unnoticed latent form until it flares up under the mercury. Any drugs which kill the spirilla cure the mercurial stomatitis, even when the mercury is continued. Arsenic and silver nitrate are the most effectual. The arsenic can be given internally or intravenously or by local application; associated with the mercury it cures the disturbance set up by the latter. This "conjugated method," as he calls it, giving neosalvarsan with the mercury, allows the full therapeutic effect of the mercury while warding off trouble in the mouth. For local treatment, silver nitrate is more effectual than arsenic, being the specific, he affirms, for external spirilla infections. The treatment which he has found promptly successful in hundreds of cases begins with mechanical cleansing of the mucosa of the patches and membranes. This is done with cotton-wound toothpicks dipped in 1 per cent. silver nitrate. The ulcerating mucosa is rubbed vigorously and cleansed of all the purulent masses and pseudomembranes, working between the teeth, and thus transforming the inflamed mucosa into a red, freely bleeding surface. The mucosa thus prepared is swabbed with a 1:15 or 1:20 solution of silver nitrate, working it into all crevices, and the procedure concludes with copious application of 1 per cent. methylene blue. The first treatment is always the longest and

the hardest to bear. By the next day the aspect of the lesions is much modified and the functional symptoms have improved. The swabbing is done once a day at first and then at longer intervals. It soon is possible to have the tartar removed and the teeth otherwise put in order, and with hygiene of the mouth, gargling with hydrogen dioxid and brushing the teeth, there is no return of the buccal infection, even although the mercurial treatment is continued unmodified. [Compare with the article by Campbell and Dyas in The Journal, June 2, 1917, p. 1596.]

35. **Castor Oil for Dressing Wounds.**—Revillet comments on the fact that castor oil never dries out, so that gauze, etc., impregnated with it never sticks to the wound, no matter how long it is in contact with it. Another advantage of castor over other oils is its characteristic slipperiness which facilitates the working in of wicks, etc., and renders their extraction easy and harmless. But its chief advantage is that it dissolves alcohol, tinctures, essences, etc., and holds them without allowing sedimentation. Perfume manufacturers use castor oil as an excipient for essences as it holds them without growing turbid or precipitating them. After considerable trials he found that 0.4 c.c. each of oil of thyme, oil of lavender and oil of eucalyptus in a liter of castor oil produced an agreeable aromatic lubricant and dressing which deodorizes at once and never irritates, while it has some antiseptic power. The dressings impregnated with this oil mixture are sterilized in a jar placed in boiling water for an hour and a half. Steam sterilization would drive off the volatile oils and might break the jars.

36. **War Diarrhea.**—Mollière declares that infectious sore throat, dental caries and gastro-enteritis might be warded off in many cases if chronic rhinopharyngitis were promptly cured. He examines the throat the first thing, when a man complains of enteritis, and swabs the throat with iodized glycerin several times a day. When there has been diarrhea for several days, typhoid or infection of the biliary passages should be suspected, even when there is no fever. A slow infection with exposure to wet and cold is liable to send the temperature below normal rather than above in some cases. With an infectious process in the biliary passages the pain appears and grows worse after walking a few miles, but it may not be severe. It is always on the right side and may be at the bladder point or McBurney point, but is diffuse on pressure except when it can be localized with the sign of Glénard's girdle. It is not accompanied by muscular rigidity of the abdominal wall, and it may be relieved by wearing a tight belt. The diet does not seem to modify it except that meat and alcohol aggravate it. Another sign is that saline purgatives do not act until after an interval twice or three times as long as usual, and, after their effect has passed off, the stools retain their diarrheic nature instead of the constipation which ordinarily follows a purge. The third sign is a tendency to jaundice in the conjunctiva after much fatigue or a heavy meal or a small dose of alcohol. A liqueur glass of brandy is rapidly followed by this subicterus.

37 *Light and Heat as Aid to Massage. L. Alquier.—p. 145.
38 *Tests of Functional Capacity of Left Ventricle. L. A. Amblard.—p. 149.
39 Technic for Removing Sequesters. (Esquillectomie en chirurgie de guerre.) H. Costantini.—p. 154.
40 *Recent Surgery and Medicine in Germany. A. Leroy.—p. 158.

37. **Treatment with Electric Light and Heat plus Massage.**—Alquier lauds the excellent results obtained with what he calls a thermophotophore which focuses the light and heat from an incandescent bulb on the region over persisting edema and relics of inflammation; its action is reenforced with massage. This combination ensures the reabsorption of everything that is resorbable by the blood or lymph passages as long as fibrous tissue is not definitely constituted. He has succeeded by this means in restoring the functional use to limbs apparently permanently crippled by cheloid cicatricial tissue or diffuse or localized induration or hard edema. He reports also the rapid improvement of lymphatic engorgement in muscular rheumatism, and in periarthritis and synovitis, even the tuberculous. He has also cured by this means cases of pseudoneuralgia and visceral trouble including palpitations of the heart with arrhythmia, dyspnea from inability to expand the chest, and certain laryngeal and gastro-intestinal troubles originating in engorgement with lymph.

38. **Test of Heart Functional Capacity.**—Amblard gives a number of charts registering the maximum and minimum blood pressure and the pulse, at rest, after moderate exercise, and after violent exercise. Some of the charts are made up from the average of large numbers of healthy persons, and others from persons with various heart affections. Whatever the pressure may be to start with, if the maximal pressure drops and the minimal rises only a very little after exertion, while the pulse becomes much accelerated, this indicates absolute insufficiency on the part of the heart unless the significance is modified by long training in physical exercise. He calls attention to this increased frequency of the ventricular wave as an aid in sifting out men whose hearts are not equal to the strain of exhausting exertion, although he admits that dyspnea on effort is the true warning signal of functional insufficiency of the ventricle.

40. **Surgery in Germany.**—Leroy reviews some recent articles on war surgery that have been published in the German medical weeklies, remarking: "The German medical majors make necropsies, and that is a superiority over other countries. They write that the war has taught a number of things, among them that when a man with a brain wound succumbs after resection of brain tissue, the ventricles are always found infected. It is this infection which is responsible for the hernia of the brain and decides the man's fate. Consequently, do not resect, but let the cerebrospinal fluid flow." He quotes in regard to wounds of the lung that they advise puncture always when there is effusion with fever even although not more than 100 c.c. of fluid can be withdrawn. In case of infection, they resect the eighth rib with drainage both front and rear. Necropsies have shown that extravasated blood above the liver passes into the pleura, and that with any lesion of the diaphragm the viscera hernia upward. The German surgeons confirm the extreme gravity of injuries of the large intestine and the mildness of uncomplicated perforations of the bladder. They advise to leave open to the air the profusely suppurating wounds, dressing them at night with an absorbent dressing of animal charcoal or pulverized sugar. As a substitute for hydrogen dioxid they use a mixture of equal parts of calcium perborate and talcum. They report six cases of gas gangrene cured under treatment with an elastic band drawn tight enough to make the limb red and hot but not enough to induce anesthesia or pain. For erysipelas they commend ultraviolet radiation, commencing with ten minutes a day and increasing daily by from one to five minutes, the distance from the quartz lamp from 70 to 100 cm. Treatment of injury from asphyxiating gases includes, during the period of agitation, injection of atropin, from 0.5 to 1 mg.; during the phase of collapse, caffein, avoiding strong doses.

41. **The Murmurs with Aortic Incompetency.**—Trémolières asserts that in young adults the murmur of aortic insufficiency is generally to be heard to the left of the sternum, in

the third interspace, instead of at the classic site as taught in the textbooks. Roentgenoscopy, always a valuable guide in cardiac pathology, will confirm the diagnosis of the aortic insufficiency in these cases. Only when the valvular trouble has reached an advanced stage and been aggravated by the dilatation of the right cavities, only then is the murmur heard at the classic site to the right of the sternum. This was the case only in ten of sixty-six cases studied; in twenty-six the murmur was heard to the left of the sternum; in twenty at the sternum itself; in nine at the xiphoid appendix, and in one case at the tip. When the murmur was heard at the left of the sternum it was usually at the inner angle of the third or second interspace; exceptionally at the fourth or still more rarely at the fifth. He explains the mechanism for this, and describes the roentgenoscopic findings. With a recent aortic lesion the left ventricle is simply hypertrophied and the aorta is vertical, and the murmur is heard to the left of the sternum. With an old aortic lesion the right cavities are dilated also and the aorta slants, and the murmur is heard to the right.

42. **Electric Reactions with Sciatica.**—Neri's article was summarized recently when it appeared elsewhere. (Abstract 70 in The Journal, p. 246.)

43. **Fat Granulations on the Ovary.**—Jayle and Bertrand give the macroscopic and microscopic findings in a case of ovarian abscess with small yellowish granulations scattered over the surface, closely resembling tuberculous processes. They proved, however, to be merely fat granulations.

45. **Vaccine Therapy of Typhoid Osteoperiostitis.**—Weil has now a record of twelve cases of ostitis consecutive to typhoid fever. Nine of the men had never been given preventive vaccination against typhoid but two had been thoroughly vaccinated, ten and three months before. Agglutination was pronounced in all although the interval since the typhoid had been one or two years or more. The ages ranged from 27 to 44, only two being under 30. In differentiating, exclusion of tuberculosis is practically the only difficulty. In some other cases typhoid fever had caused the flaring up of clinically cured tuberculosis, and the ostitis was the work of the latter. Differentiation in one case was facilitated by a concomitant anal fistula. A dental origin was discovered in other cases. In two cases the ostitis was in a rib and had caused much bulging and pain, but there was no suppuration. The bone process was of one and two years' standing but it subsided smoothly in each case under the typhoid vaccine therapy alone, and the cure has been complete during the six months to date. Vaccine therapy alone seldom cures in the suppurating cases, as the lesions are too deep and extensive for this unaided to be effectual. But complete success was attained by commencing the vaccine therapy and, after four injections, clearing out the bone lesion and then resuming the vaccine to a total of sixteen injections in all. He outlines the extensive operative measures necessary to clear out the focus, and expatiates on the highly satisfactory results obtained by this mixed treatment. The bone lesion once cleared out, healing proceeded remarkably fast and by the end of two or three months the cure seemed to be complete. The vaccine prevents reinfection of the bone, which is the rule after ordinary surgical treatment without the vaccine, and is frequent after vaccine therapy alone. By combining the two, the trouble is actually conquered. Better than this, however, he declares, is the prevention of the trouble, or at least its early and complete cure while still in the incipient stages. By detecting the bone affection early and attacking it at once with vaccine therapy, we can avoid the necessity for surgical measures.

46. **Connection between Falling of the Hair and Imperfect Teeth.**—Sabouraud gives some illustrations of the teeth of persons with alopecia areata. They indicate, he says, that some initial teratologic disturbance is responsible for the tendency for the hair to fall out, and for the defective teeth and defective growth of teeth and nails. Inherited syphilis is sometimes but not always responsible.

47. **"Cutinization" in Treatment of Fistula into Bone.**—Jayle gives an illustrated description of his method of treating fistulas into long bones rebellious to the ordinary methods. He transforms the bottle-shaped lesion into a broad open wound, and lines the walls of the cavity thus created with skin, after loosening up the skin for some distance all around the hole. To get skin enough to cover the entire circle of the opening he makes a scythe-shaped incision at each end of the opening, the straight line, representing the handle of the scythe, running parallel with the lengthwise axis of the opening. The flap thus mobilized is easily twisted around to cover the rest of the opening at each end after the skin has been sutured along each side. The curving needle is passed through the skin some distance back of the edge of the hole and is drawn out just below the periosteum where it is threaded with one end of the suture material which has been passed through the extreme edge of the skin to form a U. The two ends are thus drawn back through the skin separately and tied. Six of these threads are sufficient, each tied separately. The skin defect left by twisting the flaps around is easily corrected by drawing up the skin and suturing it. The finished operation shows an open crater directly in the bone, like a basin, with nothing but skin showing, lining all the sides down to the bone at the bottom. Jayle has done 536 operations for bone fistulas during the war.

48. **Galloping General Paralysis in the Army.**—Mignot has been impressed with the rapid development of general paralysis when it once makes its appearance in the men on active service. It runs its course in months instead of years as usual. Before the war, out of 100 cases in his service, only eight ran their course in less than a year, while among the 145 soldiers since 1914, fifty of the patients have died. The privates are sent elsewhere but the officers are kept to the end in his service. Of eleven officers with general paralysis coming on during their active service at the front, four died within six months of the onset, and three in less than twelve months. Out of seventeen officers with general paralysis there has been nothing approaching the usual remissions of the disease except in one instance.

57 *Captivitosis. C. Julliard.—p. 464.

55. **The Metabolism of Minerals with Exophthalmic Goiter.**—Kummer devotes several pages to the metabolic findings in a man of 42 with exophthalmic goiter for two years, incapacitating him notwithstanding energetic treatment and with repose. Thyroid treatment aggravated all the symptoms, but resection of part of the thyroid cured him and restored full earning capacity. The metabolism of minerals showed the same tendency as the other vital processes, namely exaggeration and instability. In the course of the research, subcutaneous injection of calcium iodid on one occasion caused effects that impelled Kocher to add a note to Kummer's report calling attention to the action of calcium iodid in this case. He suggested a trial of it on account of its efficacy in acute tetany. "If Kummer's results are confirmed by others," Kocher wrote, "they suggest an explanation for certain correlations between the parathyroids, the exophthalmic goiter and the functions of the thyroid. Removal of the thyroid seems to attenuate the symptoms of tetany. This was particularly striking in a case of semithyroidectomy for exophthalmic goiter complicated with chronic tetany. Thyroidectomy with exophthalmic goiter acts to increase the retention of nitrogen, of carbohydrates and of fats, as our operation and experiences have established. The thyroidectomy

consequently would reduce the disassimilation of nucleins, and also would reduce the exaggerated excretion of phosphorus and calcium which Kummer's research has established. This explains the curative action of thyroidectomy in tetany, a disease which, according to McCallum, is due mainly to loss of calcium. If further experiences confirm Kummer's results, and injection of calcium iodid actually does induce in exophthalmic goiter retention of phosphorus and calcium up to positive balance, we can then understand the favorable action of calcium iodid on the symptoms of tetany." [This must have been one of the last communications from Kocher's pen. It is dated April 4, and his death followed in August.]

57. **Captivitosis.**—Julliard has coined this term to express the condition of prisoners of war suffering from symptoms resembling those of a traumatic neurosis. Their obsession to be allowed to return home from their captivity maintains the morbid condition. This obsession is to the mind what a foreign body is to the tissues. The only cure, he thinks, is to make the man realize, once for all, that he has no chance for being sent home, but must live the life of the other captives and not be pampered in the hospitals as a sick man.

58 Technic for Transfusion of Blood. R. Klinger and E. Stierlin. —p. 1089.
59 *The Neurosis Problem in the Light of War Neurology. K. Imboden.—p. 1098.

59. **The Neurosis Problem by the Light of War Neurology.**—Imboden reviews the extensive literature on functional neuroses of the last three years, emphasizing that there is no essential psychologic difference between the neuroses among the soldiers and the neuroses of peace times. Human life is a struggle for existence even without the thunder of artillery and starvation blockades, and many get wounded and live on, crippled, or sink by the wayside. He remarks that the fact that so few men develop neuroses among the millions engaged in this awful warfare shows that civilization does not develop weaklings to the extent that had been feared. He regards it as significant that the professor of psychiatry at the University of Jena has recently published a manual on psychanalysis, saying that psychotherapeutic demands are now made on every physician during these years of war, and the psychanalysis movement should have general attention. Imboden declares that the one fact emerging from the war neurology data to date is the increasing appreciation of the psychic factor in the genesis of the clinical pictures of the nervous state. Nonne even advocates hypnosis in treatment, and the array of disguised persuasion methods proposed is legion: Goldstein advocates a sham injection under a few whiffs of ethyl chlorid; Weichardt the continuous bath until all the symptoms subside; Podmanizky lumbar puncture to cure abasia. The "extremely logical and extremely brutal" method introduced by Kaufmann, consisting in strong electric shocks with loud, staccato military commands to do certain exercises, has realized some surprising cures, but time has shown that relapses are liable to follow on the slightest provocation.

69. **Pituitary Extract to Regulate the Intestines.**—Pimentel reports ten cases which seem to demonstrate that it is possible to regulate bowel functioning with pituitary extract even in cases of habitual constipation or exaggerated peristalsis, as with dysenteriform enteritis in infants. He states that pituitary extract is harmless while its action on the bowel is prompt and pronounced. His patients were adults from 25 to 72 years old and, with one exception, none displayed any by-effects. The exception was a man of 42 who did not have constipation but took the extract as an experiment. Six minutes after the injection the bowels moved, for the second time that day, and peripheral vasoconstriction was noted, while the pulse dropped from 84 to 70. The dose was 1 c.c. of a pituitary extract administered by the usual technic. Some required three injections at a week's interval before bowel function was restored to normal. The treatment failed in one case, a woman of 72 whose bowels for fifty-four years had moved only after rectal injections. No effect was apparent from three subcutaneous injections of the extract on successive days.

70 *The Venereal Diseases Question. V. P. Castello and L. F. Hirzel —p. 423.
71 Return of Menstruation for Five Months to Date in Negro Woman of Ninety-Two. L. F. de Jongh.—p. 429.

70. **Venereal Diseases in Cuba.**—Castello and Hirzel comment on what has been published recently in The Journal on the measures taken in different countries to repress the spread of venereal diseases. They state that Cuba and Havana in particular are far behind in this respect. They sent one of their charity patients in turn to all the dispensaries and laboratories in town without her being able to get a Wassermann test made anywhere. Many times they have seen indigent syphilitics who had secured a dose of salvarsan but could not find any one who would inject it for them. They add that not sufficient provision for instruction in the care of venereal diseases is made in the cirriculum there. They do not approve of the idea of compulsory notification, but plead for improved facilities for teaching the diagnosis and treatment of venereal diseases, prohibition of quacks' advertisements in periodicals and the founding of dispensaries for diagnosing and treating these diseases. They state further, "The advertising of patent medicines in Cuba has become a question of fashion; 50 per cent. of all the advertisements in the periodicals are of medicines and drugs, and these exploiters of medicine have taken possession of the field of venereal diseases as their own special property. They carry their impudence so far as to advertise that this or that preparation is better and superior in its effects to salvarsan, or that this or that injection will radically cure gonorrhea. Our sanitary authorities that are entrusted with the task of watching over the public health, and the Colegio Medico, entrusted with the task of watching over the prestige of the profession, should put an end to this iniquitous exploitation. . . ." "The number of syphilitics in Cuba is enormous and is increasing every day." In one dispensary for skin diseases maintained without financial aid by one of the writers, in connection with the Hospital Mercedes, 150 of the 563 applicants since last February, or 26.64 per cent., were syphilitics.

72 Acute Malarial Ataxia. E. F. Sanz.—p. 586.
73 *Dosage for Children. C. S. de los Terreros.—p. 588.
74 Enucleation of Erythroblasts. F. Mas y Magro.—p. 592. Commenced in No. 3321, p. 566.

73. **Dosage for Children.**—De los Terreros declares that the doses for children should be based on practical experience and not on theory. The pediatrists of the longest experience are often the ones who pay least attention to the dosage

given in the testbooks, and he urges a revision of this branch of therapeutics. He is convinced that children can stand much larger amounts than those theoretically computed for them with certain drugs, and the lack of benefit from our medication is often due to the inadequacy of the dosage. He discusses in particular opium preparations, calomel, digitalis and arsenic. With arsenic in particular, small repeated doses actually confer a kind of immunity as the tissues become accustomed to the drug. He gives it usually in the form of sodium cacodylate, in the minimal dose of 0.10 gm. per day, to begin with, after a small test injection,

75 *Light Dermatitis. H. Haxthausen.—p. 765.
76 Magnesium Sulphate in Treatment of a Case of Puerperal Eclampsia. J. Kaas.—p. 776.

75. **Light Dermatitis.**—Haxthausen has been conducting research on the importance of certain substances, occurring normally in the body, for the biologic reactions to light. The work was done at the Finsen Light Institute at Copenhagen. It was found that the disintegration of the red corpuscles under the influence of chemically active light rays seems to be a process closely akin to the action of light on the skin. Certain substances in the body promote and others check this process. Albuminous substances and other colloids inhibit it, while oxygen, urea and certain elements of the bile and also hematoporphyrin promote it. The balance between these substances determines the degree of reaction to the light. There may be a preponderance of the inhibiting or of the accelerating substances normally in the body, and there may be additional factors in the form of foreign elements, or all the above factors may be combined.

77 *Immediate and Remote Results of Laparotomy for Myoma. L. Lindquist.—p. 625.

77. **Laparotomies for Uterine Myomas.**—Lindquist reports one death from pulmonary embolism among sixty-five women after removal of the myomatous uterus, and one after supravaginal removal of the uterus in 121 cases. There was no fatality in his thirty-five conservative operations for uterine myomas. Forty-one pages are devoted to tabulation under twelve headings of the total 221 cases, with the immediate and ultimate outcome, the series covering eighteen years. Nearly all of the cases were encountered in private practice. Besides these 221 laparotomy cases, he had forty-two vaginal and 152 medical cases, fifteen given roentgen treatment and twenty treated with cureting. In five cases the laparotomy was done on a pregnant woman and in most of them the pregnancy continued undisturbed. The mother and two sisters of one patient in this group had required operative treatment for myomas at some time. Climacteric disturbances from the artificially induced menopause followed in 45 per cent. of the cases, but only in 41.6 per cent. of the ninety-one cases in which one ovary was left; where both ovaries had been removed, in 51.6 per cent. Classifying the cases further by the previous condition of the ovaries and tubes, climacteric disturbances were noted in 59 per cent. of the twenty-two with previously pathologic ovaries and only in 36 per cent. of those with sound ovaries. Omitting those with merely slight climacteric disturbances, the ultimate outcome was excellent in 94.2 per cent. of the hysterectomy cases and in 81.1 per cent. of the supravaginal amputations. Evidences of malignant degeneration were found in fourteen cases; seven of the sarcoma patients are still living. The interval in one case since has been over seven years and in two over three; one died from heart trouble after four years.

78 *Pulmonary Tuberculosis in Norwegian Province. (Om lungetæringen i Finmarken.) A. Holst.—p. 889.
79 *Disease of Optic Nerve Originating in the Nose. A. Galtung.—p. 921.
80 Factors in Epidemicity. (Hvorledes man finder Genius epidemicus.) A. Magelssen.—p. 939.
81 Classification of Mental Diseases Now and in the Past. H. A. T. Dedichen.—p. 948.
82 *Sarcoma Inducing Ascending Paralysis. L. Sommerfelt.—p. 968.

78. **History of Pulmonary Tuberculosis in Norwegian Province.**—Holst analyzes and comments on the mortality from pulmonary tuberculosis in Finmarken. It has jumped from 0.56 per thousand living in 1875-1879 to 2.44 in 1910-1913. The corresponding rate for the whole country was 1.22 and 1.73. The type of the disease in Finmarken seems to be of a more rapid course than elsewhere. He is inclined to ascribe this and the prevalence of the disease to the improved traffic facilities and the fact that it is a comparatively virgin soil for tuberculosis. Holst remarks in conclusion that although the tuberculosis mortality throughout the country is comparatively low, yet the number of cases of pleurisy, which is almost inevitably of tuberculous origin, seems to be on the increase. He queries whether other remote provinces, virgin soil for tuberculosis, may not be facing a similar rise in the tuberculosis mortality as means of intercommunication are extended and traffic facilities improve.

79. **Optic Nerve Trouble Originating in the Nose.**—Galtung relates that it is exactly 100 years since Beer in 1817 first called attention to the close connection between disease in the nose and in the eyes. Galtung discusses this field and the literature on it, especially affections originating in the nasal accessory cavities and involving the optic nerve but without causing an abscess in the orbit. Even when there is manifest disease in an accessory sinus, it is necessary to exclude alcohol and tobacco poisoning, multiple sclerosis and syphilis, before incriminating the sinusitis in the etiology of the optic trouble. In a recent case a man of 30 had multiple sclerosis and ethmoiditis and also retrobulbar neuritis. As the latter persisted after the cure of the ethmoid disease, he ascribes it to the multiple sclerosis. Another patient, a man of 45, had disease in both the ethmoidal and sphenoidal sinuses, and this was evidently responsible for the optic nerve trouble. It was in an advanced stage, vision being considerably reduced. There was also peripapillary and paracentral scotoma. The van der Hoeve symptom was positive, and the operation on the cavities showed that the posterior recesses had been invaded. As soon as the accessory cavities were cleared out on one side, the scotoma on that side subsided, but on the other side it persisted unmodified until this side had been operated on also. The scotoma then subsided entirely and vision improved.

82. **Sarcoma in Spinal Ganglion.**—Sommerfelt has not been able to find in the accessible literature a case like the one of which he gives an illustrated description. The patient was a man of 28 and the symptoms indicated ascending paralysis. Necropsy revealed a sarcoma at the twenty-fourth left spinal ganglion, about 35 mm. long by 20 wide. It had a fibrous capsule and was connected with nerve roots, but it lay entirely outside of the spinal canal. There are twenty-one cases on record of tumors in the gasserian ganglion, including three sarcomas and four endotheliomas. Anatomically they resemble this case, but clinically differ completely from it as the symptoms are only those of a brain tumor plus symptoms on the part of the trigeminal nerve.

83 *Lipemia in Rabbits during Anemia from Hemorrhage. V. Ellermann and E. Meulengracht.—p. 1287.
84 Abbott's Method of Treating Scoliosis. E. Nyrop.—p. 1297.

83. **Lipemia in Rabbits.**—Ellermann and Meulengracht report considerable research on lipemia induced in rabbits during anemia from losses of blood. Their tables and other data confirm Milne's assertion (1913) that extremely pronounced lipemia develops in rabbits after severe hemorrhages but not under the influence of toxins. The cholesterol content of the blood increases along with the fat content. The fat seems to be derived from fat deposits in the body. For its passage into the blood, the loss of the blood serum—with loss of its fat-splitting ferments—is probably responsible.

GRADUATE EDUCATION IN THE CLINICAL BRANCHES, AND THE MINNESOTA EXPERIMENT *

E. P. LYON, Ph.D., M.D.
Dean, University of Minnesota Medical School
MINNEAPOLIS

On the 24th of May just past, in the faculty room of the Medical School of the University of Minnesota, Rood Taylor was examined for the degree of Doctor of Science in Pediatrics. About ten persons were present. These included the associate professor of pediatrics, presiding in the absence of the chief of the department; two professors of anatomy, one of whom has specialized in the anatomy of the infant; one professor of physiology; two of medicine, and an associate professor of chemistry.

For more than two hours a lively game went on across the invisible net separating faculty and student. One after another the professors served swift questions; and the answers came back, usually, fair in the court—sometimes (be it whispered), lobbed quite over the heads of the faculty players! Occasionally, however, the young player's racquet seemed full of holes, and the questions went past him into indefinite vacancy.

First he was asked about his thesis, which happened to be on "Hunger in Infants," an extension of the work done here at Rush by Carlson and Ginsberg. Then followed inquiries of more general scope, on the diseases of children, on anatomy, on physiology, on medicine. Finally the professor of chemistry, field of the candidate's minor, contributed interrogatories concerning hydrogen-ion concentration.

At last the game was declared a "love set"; the candidate, who had really done very creditably, was voted "passed"; and all went home without thinking that they had taken part in an occasion that may come to be considered one of the historic marks in the advance of medical education; for the examination of Dr. Taylor was the first ever given for an earned doctor's degree in a clinical subject.

To some phases of the experiment leading up to the granting of this degree I invite your attention.

As I see it, the fundamental elements of the situation are expressed in six almost self-evident propositions:

Proposition 1.—The important facts of medical science have become too many for one man to know, and the necessary technical processes have become too complex and numerous for one man to master. Division of labor or specialism is advantageous and unavoidable. This is true alike for better practice and for surer progress.

Proposition 2.—Systematic graduate training in the clinical specialties, including advanced work in the underlying sciences, is a necessity. This means cooperative and coordinated educational processes.

It is true that the first specialists had to make both themselves and their specialty. It is true that many excellent men in every profession have been self trained. Nevertheless, both economy of effort and the legitimate interest of the public demand that the education of specialists be systematized and standardized.

Proposition 3.—The safeguarding of the public demands some method of certification for specialists. This is, perhaps, quite as important as the primary certification or licensure. How is the average citizen at the present time to proceed in order intelligently to select a competent surgeon? The answer is, "It can't be done." Perhaps as good a way as any is that of the Minneapolis lady who went into a big office building, stood in front of the directory of physicians, closed her eyes, said a little prayer, put out her hand, and had her appendix removed by the physician whose name her fingers thus blindly hit on. If she found a competent man, it was a miracle, or else a lucky chance; for in that directory the names of the experienced and the inexperienced, the highly trained and the self-announced, stand forth in type of equal size.

Proposition 4.—The progress of medical science is of the utmost importance alike to individual human need, to civilization as a progressive ideal, and to the profession of medicine as a satisfying life work for men of the best intelligence.

Proposition 5.—The leaders of medicine as exemplified by the class of specialists should be more than practitioners. They should be scientists.

Real success in practice demands scientific method and the scientific spirit. Leadership in the profession should rest on productive scholarship. The education of specialists should be planned with that end in view.

Proposition 6.—The progress of medical science demands more and more rigid scientific preparation on the part of all physicians, but particularly on the part of investigators. Some one has said that the future great discoveries of physics will be made in the sixth decimal place. In a similar way, it seems to me, refinements of quantitative methods and a more comprehensive, intelligent and exact use of statistics are likely to add most of the great new truths of medical science. Nothing is fully known until it can be expressed mathematically. All this implies more rigid training for the medical investigator of the future.

Every one of my six propositions involves a task appropriate to a university. The practical questions arise as to the extent to which a given university may undertake these tasks for the medical specialties, and how to go about what is undertaken. At the Univer-

* Read at the Commencement Exercises of Rush Medical College, June 13, 1917.

sity of Minnesota we are feeling our way in both these particulars, and some account of our experience will be more valuable than further theoretical disquisition.

First, however, let me say that for years every good medical school in the country has been doing graduate work in the clinical branches and is doing it now. It is unsystematized and for the most part unrecognized; but nevertheless in the clinics and laboratories there are always young graduates, as voluntary assistants, whose chief purpose is to learn. Many of the best men on the faculty of Rush Medical College were undoubtedly thus trained. They were not formally instructed; there were no requiremnts of entrance, attendance or examination. No degrees marked the completion of their postgraduate education. Nevertheless the men worked in a university atmosphere. The equipment and libraries were at their disposal. The critical guidance of the master was unconsciously exerted. These are not self-trained men in the sense that I have previously used that term. They are university products. What we have attempted to do at Minnesota is to systematize what was already going on in our university (as in others), and give it consciousness and individuality.

As soon as one attempts to systematize, one discovers lack of symmetry. As soon as one attains consciousness, new phases of endeavor open to view. Both these experiences have been ours at the University of Minnesota. From a vague feeling of the need of systematic education in the medical specialties, we have come to realize the need of training for medical research, for medical teachers and for the higher walks of practice. At the present time one may perhaps regard our effort as an officers' training school preparatory to the larger work that must attend the drilling of the entire army of specialism, a task gradually to be accomplished, I hope, through the united effort of the universities and clinics of the country.

THE ADVANCED DOCTOR'S DEGREE IN MEDICINE

As far back as 1910, our faculty, impressed with the need of graduate training for surgeons and of standardizing surgery as a special branch of medical science, decided to organize a two year course and offer a special degree. A course in ophthalmology was also proposed; but, owing to various causes, the matter was postponed. In the spring of 1914, however, the question was revived, and with it the perplexing question of assistance in our teaching clinics. It was argued that if the same hired assistants were used year after year, the graduate educational opportunities of our clinics would be largely lost; that it was better to have a change from time to time—better in the sense that more medical graduates would obtain added training while assisting. We decided, therefore, to combine a fruitful idea adopted from the University of Michigan, namely, the full-time small salaried clinical assistantship on limited time appointment, with our original plan of an advanced course leading to a graduate degree. We started with six teaching fellowships on a three year basis on progressive annual stipends of $500, $750, and $1,000, and arranged that the successful completion of requirements to be formulated should lead to the degree of Doctor of Science in the specialty concerned; for example, D.Sc. in Surgery or D.Sc. in Ophthalmology.

These requirements have gradually been worked out in practice under the Graduate School Medical Committee, and are as follows:

1. Requirements for acceptance as a medical graduate student: (*a*) a bachelor's degree or equivalent (which may have been obtained in a combined B.S. and M.D. course); (*b*) an M.D. degree from a good school, and (*c*) a year's internship in an approved hospital.

2. Requirements for the advanced doctor's degree: (*a*) at least three years of graduate study distributed chiefly between a major subject and one or two supporting or minor subjects; (*b*) a reading knowledge of German and French tested by special examination; (*c*) an acceptable thesis, which must contain the results of original investigation, and (*d*) final written and oral examinations before committees of the graduate faculty.

It will be noted that the requirements for entrance to graduate work in the clinical branches of medicine are higher than those for graduate work in any other department in the whole university. This is due to the peculiar position of the clinical subjects with respect to dependence on a number of sciences and because a reasonable experience in practice, for example, an internship, is desirable before graduate study begins. Apart from this difference as to entrance, the requirements are substantially those required in the good universities for the degree of Doctor of Philosophy, or for that of Doctor of Science when the latter (as at Minnesota) is given as an earned degree.[1]

As to the division of the candidate's time, it appears that approximately one third to one half will be devoted to the major (exclusive of thesis), and will include the clinical and technical experience necessary to insure fair skill in the specialty chosen; from one fourth to one third will be spent in the fundamental laboratories, and from one fourth to one third on the thesis. This again is not unlike the distribution of time usually worked out by a Ph.D. candidate in any of the sciences.

As to the individual program, it was apparent from the start that no two men could be trained exactly alike. Graduate education can be done only to a limited extent in classes, and in the clinical branches apparently hardly at all. It consists essentially in placing the competent student in contact with the materials, apparatus and other facilities of learning and allowing him, under suggestive and critical guidance, to educate himself. Consequently, each student has an adviser; and with him and the dean of the graduate school, the student works out his general program for the three years' course and his specific work from semester to semester, which program must finally be approved by the graduate school medical committee.[2]

---

[1] I cannot entirely agree with Dr. L. B. Wilson (Science, 1917, n. s., **46,** 127) that an advanced degree in medicine stands for more than an advanced degree in a fundamental science. It is true that the medical man has much knowledge that the other lacks. So also a Ph.D. in Chemistry has much knowledge a Ph.D. in History lacks. It is true that more time beyond the bachelor's degree will be required for the doctorate in a clinical branch than for a doctorate in pure science. But the Ph.D. or D.Sc. represents not time essentially, but rather attainment in science, and particularly in research. In this respect, the advanced degree in medicine will mean the same as that in any other branch of learning.

[2] Following is the three year program of Dr. McWhorter, fellow in surgery: For the year 1913-1914 (including summer) and first semester, 1914-1915; mornings in the university hospital as assistant and in charge of clinic clerks (undergraduates); did minor operations. Afternoons divided beween anatomy, pathology and experimental surgery. Second semester, 1914-1915, summer and first semester 1915-1916; forenoons, largely independent work at the hospital; did 150 major operations (under supervision when necessary). Afternoons, two thirds on experimental work (completing thesis); one third teaching surgery on cadaver and on animals. Second semester, 1916-1917, at Rochester, working in the Mayo Clinic in cystoscopy and roentgenoscopy. Dr. McWhorter published, besides his thesis, an original paper in anatomy and one in experimental surgery.

In the fall of 1914, then, under general ideas, since that time worked out in detail as described, and with the nucleus of teaching fellows, to which a few other students were added, graduate work in the clinical branches began at the University of Minnesota.

INSTRUCTION AT THE MAYO CLINIC

While all this discussion and preparation through several years had been going on in the university, the Mayo Clinic at Rochester, unhampered by tradition, and on the other hand, in a measure, unguided by scholastic ideals, had gradually developed into an informal graduate school and research institute. The young physicians hired as assistants could not help but learn many things in handling the large and varied material of this clinic. This was the absorption process to which I have already referred as a form of graduate work always going on in medical school clinics.

The absorptive process acts best on the prepared pabulum of well established routine. It contributes well to the learning of technic and to the acquisition of practical experience, but not so well to the gaining of solid foundations in science or to the stirring up of research aspirations.

Gradually at the Mayo Clinic a more conscious effort was made to give instruction. Men were employed to carry on research, and their assistants were guided in investigation. The library was strengthened and the laboratories were thoroughly equipped. By 1914, as I have indicated, it would have been entirely appropriate to speak of the Mayo graduate medical school, although there was no formal organization of that name. No degrees were granted, nor was there any course of study or legal authority. The assistants were called fellows, but no condition of appointment except the possession of an M.D. degree was imposed. The fellows stayed in the clinic varying lengths of time, but usually three years. Many of the earlier ones were taken into the organization.

Meanwhile also the Mayo brothers had been accumulating a fund with which to endow the work of their institution. By the fall of 1914 this fund had reached a milion and a half. Moreover, it had become clear to the Mayos that the endowment would best fulfil their fundamental purpose if the income were perpetually devoted to medical education and research.

At this stage and proceeding on the initiative of the state university, the proposal was made that the clinic affiliate itself with the medical school for the cooperative conduct of graduate medical education according to the plans which the medical schol had formulated. For the carrying out of this proposal the educational and research work going on at Rochester was separated from the clinic and incorporated under the name of the Mayo Foundation for Medical Education and Research. All exclusively scientific workers became employees of the foundation. Others were exclusively clinic employees or were employed part time in each institution, according to the distribution of their work between research and the money-making medical practice of the clinic.

This arrangement was made and the foundation was created, in order that association between the university and a private business might be avoided. Those in charge of the negotiations on both sides believed, at the time, that such a connection would be "wrong in principle," since one of the parties to the proposed arrangement was a state university. The plan, therefore, was to affiliate the foundation and not the clinic with the university. We believed that this was legally and educationally feasible. The preliminary documents were drawn up from this point of view.

However, as many know, the proposed affiliation did not escape criticism. On the contrary, an organized effort was set on foot to defeat it. In two successive legislatures strong efforts have been made first to prevent and latterly to annul the affiliation. The university has won both struggles, and public opinion is certainly in favor of a continuance of the cooperative experiment entered into by the University of Minnesota and the Mayo Foundation, for the trial period of six years agreed on in 1915.

I mention this controversy, not simply as an item of historical interest, but because out of it has come a change of ideas, in my own mind, at least, concerning the fundamental relations involved. I have frankly come to believe that our municipal and state educational systems do wrong to stand aloof from practical business. The purpose of our schools is to prepare men broadly for life. Surely practical training, say of a physician, is part of such preparation or education. To confine such practical training to practice on paupers in public institutions limits opportunities, is undemocratic, and savors of phariseeism. The ideals of education must not be considered something holy and apart; something enshrined and cloistered; something robed in white and to be kept unsullied from the world. No, the ideals of education are to be taken into every-day life and used to lift it up.

I think the Cincinnati plan of engineering education should be carried down into the high schools and should embrace all sorts of trades and professions. It would tend to democratize secondary education and to give it seriousness and purpose. It would prevent the abrupt cutoff between those who go into the trades and those who go into the colleges and learned professions. I believe, to be more specific on the question of medical education, that eventually every ethical private clinic in the country—every clinic large enough to afford advanced training for even one young medical graduate—should be affiliated with some university which should have the power to supervise that man's graduate training and in the end should attest, after proper examinations, his technical proficiency.

Just exactly as the engineering student at Cincinnati gets his practical work in shops or building construction in actual operation under private management and his theoretical training in university classes, the whole being finally attested by a university degree, so also the proposed medical specialist should get further practical training in actual practice under other specialists, and further scientific training in university laboratories, the whole contributing to the diploma or certificate which should confer his moral, if not his legal, right to work independently. I estimate that this is the only way by which the universities can contribute in any large measure to the practical training of specialists and can assume the responsibility for their certification before the public.

This is a large task—one to be undertaken conservatively and gradually, but nevertheless without delay or temerity. Careful supervision, careful selection must be exercised. The leading specialists must be urged and taught to make their clinics more than places of business. The cooperation of the College of

Surgeons and of the special societies must be sought. But the universities must take the initiative and assume lasting responsibility. The undoubted reflex effect of a university connection should appeal to competent specialists and make the task of securing their cooperation easy. As the state-wide campus has become the watchword of agricultural colleges and state universities, so the nation-wide clinic should be the ideal in the training of medical specialists.

Coming back to the University of Minnesota and its problems, I believe that the university should maintain close relations with the Mayo Clinic, a private business, just as long as that private business is properly conducted and furnishes facilities for education. I believe that the university should see that the business is kept honest and proper. If in this sense the affiliation should prove a perpetuating agency, as charged, I should be glad. Surely at the present time the prestige of the university can add nothing to the Mayo Clinic; but that the ideals of education and research should become a stabilizer and ruling motive of all private business is a consummation devoutly, yea reverently, to be wished. If this confession of heresies rejoiceth the soul of our opponents in the "late unpleasantness," I shall also rejoice.

Moreover, our controversies over the affiliation have led, I think, to an earlier clarifying of the eventual legal relations of the foundation to the university than might otherwise have occurred. It is now plain that the Mayo Foundation will be a definite part of the University of Minnesota, being indeed the name of an endowment fund for graduate medical education and research wholly controlled by the board of regents. As a separate corporation, the foundation will cease to exist when the trial period is over. Moreover, in case the clinical facilities at Rochester should degenerate, it will probably be possible for the university to remove all of the work to other places, which some people think may some time be desirable.[3]

RESULTS OF AFFILIATION

So much by way of digression. I now return to my main theme. By the opening of the session of 1915-1916, the temporary affiliation (not with the medical school, as originally contemplated, but with the graduate school), was in effect. Members of the foundation staff at Rochester had been made members of the university graduate faculty, and those fellows at Rochester who could qualify were enrolled in the graduate school. We have had, therefore, to date three years' experience at Minneapolis and two with the Mayo Foundation. What have been the results?

In the first place, to some extent at Minneapolis and distinctly at Rochester, the effect of the graduate school standards on the quality of men appointed as fellows and admitted as students has been marked. It is doubtless clear to all that our experiment is one in intensive education and that we are not at all concerned in this discussion with short courses for ordinary practitioners who desire to "brush up," although the desirability of such courses, in case they can approach the antebellum standard of Vienna, is freely admitted. For such short courses admission standards would defeat their avowed purpose; but for real graduate work the sorting of candidates is important. The graduate school has the machinery and long established standards for this purpose. This is one reason why graduate work in medicine should be in the graduate school and not in the medical school.

Counting the fellows at both places, and a few others, we have had, during the past year, fifty-eight graduate students in clinical subjects at Rochester and seventeen at Minneapolis, or a total of seventy-five. These are distributed as to major interest as follows: medicine (including neurology), 15; surgery (including orthopedics), 46; obstetrics and gynecology, 2; ophthalmology and otolaryngology, 7; pediatrics, 5. These seventy-five students did their undergraduate work in twenty-six different medical schools, so that we have in our graduate school in the medical group quite as cosmopolitan a body of students as in any other division of the university. We believe this is desirable.

Seventy-five students do not seem a large number,[4] yet it is apparent that our facilities, including those at Rochester, will accommodate only a few more. Probably few universities having undergraduate teaching obligations could give good training to more graduates than Minnesota. Moreover, the number eligible for degrees theoretically might annually be one fourth or at most one third of the student number; say, fifteen to twenty a year from Minnesota. It is such calculations that have caused me to state that if the universities are really to be an effective factor in the training of specialists, they must affiliate with themselves a large number of private clinics.

The University of Minnesota has taken a step in this direction in its recent approval of the clinics of Dr. Todd in Minneapolis and Dr. Burch in St. Paul, for practical training in ophthalmology. Each of these men agrees to support one fellow who shall divide his time between the private clinic and the university. This fellow is to be allowed one half of the first year's graduate credit for strictly technical and diagnostic work in the clinic, but not more, unless clinical work of a higher type than ordinary routine office procedure shall be provided and "evidence of satisfactory productivity in investigation connected with this work be furnished." These provisions indicate the type of university control that we deem to be necessary in affiliating private clinics.

Many other phases of interest from our experience might be noted, but I prefer to confine myself to those which have come to the front in connection with the presentation of the first group of candidates for the advanced doctor's degree. We shall grant four such degrees at our commencement tomorrow; and they will be, as I have indicated, the first ever conferred in clinical science. I shall note at random some interesting happenings of the past few weeks.

First as regards degrees: As I stated, we offer the degree of doctor of science, this having been always an earned degree at Minnesota. One of our candidates, however, asked for the degree of doctor of philosophy in surgery. This was Dr. McWhorter, a Rush graduate known doubtless to many of those present. His request was granted.

Now the question presents itself, should not the Ph.D. degree indicate the highest earned distinction in surgery or medicine as well as in physiology or chemistry? I think it should, and that Dr. McWhorter in making his request showed a fine appreciation of the desirability of continuity and uniformity in academic degrees. New degrees always have indefinite significance.[5] The Minnesota experience shows that graduate work in clinical science can be conducted under the same standards and rules as graduate work in laboratory science, or in social science, or in agricultural science, or in languages. No new degrees should be introduced until the old ones distinctly fail to meet the need. I doubt not that those who will guide your new graduate work in medicine here at Chicago will take this view, and I trust that the Ph.D. degree, the honorable mark of so many Chicago men who are leaders in all the fields of natural and social science, will be the mark also of those who go out from here as leaders in clinical science.

---

[3] Since the delivery of this address, a proposition to the above-mentioned effect has been made by the Drs. Mayo and accepted by the regents of the University of Minnesota. The foundation is now an integral part of the university.

[4] In addition to these, twenty-eight were enrolled in the fundamental departments, anatomy, physiology and physiologic chemistry, pathology and bacteriology. Of these, ten worked at Rochester, and eighteen at Minneapolis.

Medical men are, I believe, unfortunately disposed to look lightly at the word "philosophy." It seems to them to connote unpractical theorizing. I should like, as a long resident but never quite a naturalized citizen of medical land, gently to chide my clinical brethren, for I think that quite as much unpractical and unscientific theorizing is raised per acre in the clinical field as anywhere else in the broad world of learning—and think how many acres there are in that field! One of the most striking features, by the way, brought out by the recent examination of candidates at Minnesota was the lack of philosophical and historical background for their knowledge. Medicine is top-heavy and ever spreading. How to keep the foundations solid and commensurate with the superstructure will always be a big problem in graduate medical education. The philosophy and history of science and of medicine should find a place in every scheme of graduate study.

Each of our students works, as I have said, under an advisor. It is but natural, therefore, that considerable diversity should exist in the courses which have been pursued by our candidates for degrees at this commencement. Some advisors lean more to the practical side than others and neglect the fundamental sciences. Some advisors have kept their students in contact with cases to the practical exclusion of opportunity for research and reading. An apparent result of this policy is seen in the fact that the theses of two candidates were rejected as inadequate for the doctor's degree, from the standpoint of original investigation. These candidates were accepted for a master's degree. Their examinations revealed a grasp of diagnosis and practical surgery quite equal to that of any of the others. They lack only the evidences of original research.

All this shows that we shall fight again, and every graduate school of clinical specialities will fight again, the old battle in education between the theoretical and the practical, between pure science and applied science, between principle and method. A recent setting of the question as applied to army officers is beautifully put by Donald Hankey in his book, "A Student in Arms." He finds, as all must find, that both the university and the practical school (in his case the military school) have something necessary to contribute. I recommend his essay to all interested. Beyond a few dogmatic statements I shall not go into this question.

I believe in a solid scientific foundation for the undergraduate medical course and a few feet more of well-seasoned concrete for the big guns of specialism. I point to the fact that the physician will see sick people all his life; chemical and anatomic laboratories, probably, for a limited period only. I hold strongly to the doctorial thesis, first, as evidence to the faculty that the student has caught the scientific idea; secondly, as evidence to the scientific world of the type of work the university is doing. I believe, finally, that that thing you call judgment—surgical judgment, let us say—which is so much more than manual dexterity or delicate sensory discrimination or intelligent understanding of isolated phenomena, is better developed from a hundred cases studied exhaustively, considered in all aspects, read up in the literature, worked over in the laboratory, than from a thousand cases passing, with blending after-images, in the rapid cinematograph of hospital routine.

All this makes me believe that at the Mayo Clinic, and in all places where clinical graduate work is undertaken, the student must be held back from clinical plethora, from engorgement with routine observation, diagnosis and care of the sick. He must be given time for laboratory and library work; for meditation and expansion; for the development of originality and the evidence therof—his doctorial thesis. If we don't do this, the research aspects of our work will dwindle away. Our product will be trained and safe, but sterile. Our graduate medical schools, of which so much is just now expected, will be amplified, but not glorified, polyclinics.

And for all these reasons I believe that graduate work in medicine should be closely allied and alined with and, indeed, a part of the regular work of the graduate school. The restraining hand of the dean controlling the graduate work of all the arts and sciences may save the youngest child, medicine, from many a disastrous fall.

But over against the necessity for substantial science as part of clinical graduate work, I see the need for the technical proficiency that comes from repetition and for the diagnostic skill that is not so much born as derived from repeated observation. We shall always have to compromise between the theoretical and the practical. The question is where to draw the line. I say, keep it safely on the side of science.

In this connection I wish to present the case of one of our candidates which illustrates an unexpected turn of our educational machine. This man for three years held a fellowship in internal medicine. He was most ingenious in attacking all kinds of problems dependent on refined physical apparatus. His interest and thought were all in this direction. He was full of problems and of enthusiasm for research. But his examination developed that his knowledge of internal medicine was hardly better than that of a senior student, and he frankly confessed that he had no interest in practice. Our whole plan had been to produce a combination of scientist and practitioner; but here the amalgamation failed from the practice side, just as with others, in a measure, it had failed from the science side. It was plain that the degree of Doctor of Science in Internal Medicine as a mark of a trained specialist was a misnomer for this candidate.

---

[5] Some years ago a student applied for admission to the St. Louis University Medical School, presenting a certificate indicating that he had an "M.A." degree. The college issuing the certificate was an unknown Kentucky institution; but I judged that its master's degree must be at least equal to a high school diploma (at that time our standard entrance requirement), and therefore admitted the candidate. It soon became apparent that he could not carry the work of the medical course, and inquiries developed the fact that the degree he possessed was "Master of Accounts!"

He was given the degree of Doctor of Science without designation as to department.

Of the various requirements for the advanced degree the reading knowledge of French and German has been, in our experience, the hardest for medical graduate students to meet. Although all of our candidates had at least the two years of college work that is now the accepted minimum standard of entrance to the better medical schools, their linguistic training was evidently very weak. Moreover, during their period of fellowship, particularly at Rochester, they do not appear to have been impressed with the necessity of acquiring the languages and using them as tools. I feel that this is evidence that the advisers of these students did not point out the library as the great repository of knowledge and did not insist on systematic reading.

A knowledge of the principal languages of science is a universal requirement for the Ph.D. degree. The degree in medicine cannot be placed on a lower level than that in history or psychology or chemistry. Moreover, the enormous medical literature in German and French renders it imperative that every investigator and every progressive practitioner should know these languages. Otherwise, he can never keep abreast of the times and must always get a large part of his knowledge through belated and abbreviated abstracts. When the war is over, the commerce of science will be reestablished and its essential medium of exchange is found in the three great languages, English, French and German. They are, moreover, a mark of culture and a guide to that tolerance and sympathy which are characteristic of a true scientist. For all these reasons the graduate school at Minnesota adheres to the language requirement for advanced degrees in medicine.

There are other questions raised by our experiment to which, if time permitted, I should like to direct attention. For example, to what extent should graduate work in clinical science be subsidized, as, for example, by our system of fellowships? Of course, these are really assistantships. The recipient of a stipend earns it. The question may be raised whether young doctors without financial aid, after the long and expensive M.D. course, can afford the time and money for such a term of graduate study as I have described. Would our plan, if made universal and not subsidized, tend to shut out the poor man from the higher walks of medicine or unduly delay entrance into specialism? I leave this for you to consider. The question as bearing on undergraduate medical education has been touched on editorially several times in The Journal of the American Medical Association.

Likewise, it would be a delight to consider the proposed new degree for specialists who are so lacking in energy that they cannot produce a thesis, namely, the degree of "Doctor of the Practice of Medicine." In imagination I can see this striking trademark stenciled on the smug and satisfied sacks ground out by every so-called "practical" educational mill in the country. But I hope that neither "now" nor "eventually" will the "Doctor of the Practice of Medicine" be added to the grist of medical degrees produced near the Falls of St. Anthony.

CONCLUSION

Passing by these interesting topics I feel that I should attempt to point out to you, the members of this graduating class, how the new movement in medical education may relate itself to, and possibly change, the practice of medicine into which you are about to enter. The next thirty years will be your generation—yours of all the thousands of generations of men; yours to grasp, to shape, to live. In it you will make your mark deep or shallow, enduring or without a visible trace. But it will also make its mark on you. What are the changes to which you may have to adjust yourselves?

What, first, of private practice? There are those who will tell you that private practice is going out; that the old family doctor is already dead. They say that in these days of organization and cooperation, of hospitals and automobiles, of specialism and efficiency, there is no room for the family doctor.

There are those who argue for the family health officer to keep everybody well and turn over to the appropriate specialist any who by unreasonable chance become ill. Others see the whole medical business socialized, and medicine, like education, supported by the state as a free gift to the people. The group system has its advocates and has made notable progress.

I am in sympathy with all these movements. They should have your careful consideration, and to such extent as may be, they should work themselves into the life complex of your generation. Moreover, the evils of the present competitive system of medical practice, with its dollar baiting, its unjust distribution of emoluments, its inability to render equal and the best service to all classes of mankind, are apparent and must be improved wherever possible.

Nevertheless, I perceive that the practice of medicine is deeply rooted in that thing we call human nature; that it gets back and down to the fundamental instinct of survival, and rests firmly on the eternal rigidity of protoplasm. Changes will undoubtedly take place in the practice of medicine. Perhaps we can foresee the trend of such changes. We may admit that this is an age of unusually rapid social evolution. But still we must see that it is evolution. New species do not spring unheralded from the inorganic world. I predict that general practice will endure, will adjust itself to specialism and to group medicine and to public medicine. In the ecologic relations that shall be developed I predict that the ancient plant of private practice, rooted so deeply in human nature, will still be the center around which the newer varieties will flourish.

Certainly it is not hard to prophesy for the next thirty years and to declare that most of you for several years and many of you for life will be family doctors; better age for age and stage for stage, than your fathers, but following, nevertheless, essentially in their footsteps and entering into the same intimate personal and family relations with your patients. I think you should look on that as a good life, and that something more than the current and "exaggerated" rumor as to the demise of the family doctor should be needed to drive you from the ancient and honorable and useful career of private practitioner.

At the same time all of you should study and take part in the new movements in medical practice. Some of you, under favorable circumstances and in favorable localities, will, I trust, take part in those cooperative ventures that are coming to be known as group medicine. Some of you will be in public health work as school physicians and the like. I trust you may hit on a happier day than this and be able to treat as well as diagnose. At present, the school physician says, "Yes, you have diphtheria. Run along and see a doctor." It is as if, when a man is attacked on the street, the policeman should say, "Yes, you are being robbed. Hustle quick and hire a private watchman to defend you."

Others of you, finally, will prepare for the higher but narrower work of specialism. You will bear in mind that every narrowing of interest tends to narrowing of sympathy. You will do your best to counteract this tendency. As the field of view becomes smaller, as in the microscope, you will cultivate that imagination which can see the whole. You will recognize the need of further training and will not be content with a specialism that is self-announced and without foundation.

You will not be content to repeat in indefinite sequence the procedures and practices of others. You will not be satisfied to be resonators. You will sound a note of your own. You will find out something new. You will go forward to your special work, if not with an advanced degree, such as I have described, at least with a training and with ideals approximately such as are here laid down. You will be scientific specialists—scientific surgeons, scientific pediatricians, etc.—and to your work will come a pleasure and a compensation not to be found in routine, and not to be derived from much doing and much getting and much hoarding away.

THE MENACE OF MOUTH INFECTIONS *

OLIVER T. OSBORNE, M.D.
Professor of Therapeutics, Yale University School of Medicine
NEW HAVEN, CONN.

There is no more impressive sequence than the presence in a patient of a disease or abnormal condition, such as infected teeth or gums, and the later surgical eradication of the focus of infection; or, to make the sequence terse and logical, let us put it thus: patient; ailment; crowned, bridged or decayed teeth, inflamed gums, or pyorrhea, or all of these things; roentgenograms of these suspected areas demonstrating pus and degenerated bone; operative demonstration of pus sinuses and cheesy, broken-down bone; and lastly, but unfortunately not always, the cure of the patient.

In this age, in which the laity has acquired from periodicals a smattering of medical science, and therefore thinks it has a perfect right to criticize medical men and to ridicule what they term "medical fads," let me urge that the nearest relative of the patient be present at the dental operation, and be placed in close proximity to the foul tooth, foul crown, or foul pus that is extracted from the mouth of the loved one. I know of no more impressive demonstration to the ordinary layman, and he often becomes a hysterical enthusiast for the removal of infected teeth, or even of those that may possibly be infected.

MENACE OF CROWNED TEETH

Cruelly awakening to the physician is the demonstration of a bacterium in the blood or in a distant lesion, and a late demonstration of the same germ in an extracted tooth or in the secretions of a pocket in the gum. I do not believe that there is a greater menace to health today than crowned and bridged teeth, to say nothing of imperfectly filled and dead teeth, and of pyorrhea alveolaris. Furthermore, infection of the tonsils and the sinuses adjacent to the nose must never be overlooked. If such infection has not caused symptoms, it will do so, and its eradication is the only safety.

From infected areas in the mouth many pathogenic organisms have been isolated, probably the most dangerous being the pneumococcus and the *Streptococcus viridans*. We do not know how many pneumonias, following or accompanying influenzal affections, occur, because pneumococci are being carried in the mouth. We do not know how many times irregularity, weakness and actual disease of the heart are due to germs harbored in the mouth. Neither do we know how frequently the *Streptococcus viridans* is the cause of heart disease or adds its fatal potency to an already established chronic disease.

We do not know much about the *Endamoeba buccalis*, but we do know that it is probably always accompanied by other germs, and especially by the pyogenic germs. Pyorrhea alveolaris is unquestionably due to infection, but this kind of infection and inflammation does not often occur unless there is degeneration of the gum tissues, and such degeneration most frequently occurs after 40 years of age. It may be here noted, parenthetically, that chronic colitis, or at least decomposition in the colon, also occurs most frequently after the age of 40, and both of these conditions are very frequent in people in middle life. Is the intestinal disturbance a sequence of the mouth infection?

Connellan and King[1] have isolated a nonpus-forming diplococcus which they believe produces dangerous toxins. They find these germs in the crypts of tonsils, and patients suffering from arthritis, asthma, endocarditis, myocarditis or nephritis have been found to harbor these germs in their mouths. They advise producing an autogenous vaccine and using this for some time before such diseased tonsils are eradicated.

It is not my purpose either to offer or to discuss roentgenograms of damaged teeth and gums; but let me assert that no dentist should devitalize, or attempt to fill the roots of a devitalized tooth, which is to be preserved, without the aid of roentgenograms; that every case of pyorrhea alveolaris, every suspicious root, and occasionally all crowned and bridged teeth should be subjected to the scrutiny offered by the roentgen ray. It is useless to agree on the removal of one infected tooth and possibly leave other infected teeth in the mouth of the patient, and yet such carelessness is repeatedly agreed to by both physician and dentist. Also, it is difficult to compel a dentist to operate immediately on all infected areas. He does one thing at a time, and then takes up something else. What surgeon would remove one point of infection and leave half a dozen others, or even one other infected area?

There must be hearty medical cooperation between the physician and the dentist in order to decide, in any individual patient, what teeth shall be preserved, what teeth must be removed, and how best to treat infected gums; also what part a diseased condition of the patient plays in the mouth condition.

M. I. Schamberg,[2] a noted New York dental surgeon, says:

> Crown and bridge work, as well as all work upon pulpless teeth, should be conducted by men who would specialize in that work, and who would, through the medium of x-ray, satisfy themselves that they are not putting a beautiful super-

---

structure on a weak foundation. Roentgenograms should be taken from time to time after the insertion of such pieces, to determine the state of health or disease of the hidden parts. Patients' mouths should be kept free from infection at all costs, even though it should mean the removal of every tooth in the head. If it can be done without sacrifice of the teeth, so much the better, but a toothless mouth is to be preferred to one containing a single focus that menaces the health of the patient.

It should also be urged that however well a patient is, these germs of infection, wherever they may be, are ready to do him some injury whenever an acute infection attacks him, or when his own systemic strength is in any way reduced. They are all waiting an opportunity, and how can we excuse a physician for omitting to study his patient's mouth? How can we excuse the dentist who waits until tomorrow, or next month, or six months hence before he removes a source of infection which he has recognized? Or how can we excuse a dentist for carelessly constructing bridges or crowns in the mouth of a young patient, knowing the danger from infection in the years to come? In other words, have we the right to crown to the gums, even if they are wonderfully well fitted? Have we the right to construct permanent bridges, when an aseptic bridge or a removable plate is more sanitary?

IODIN INJURIOUS

I do not propose to discuss the treatment of pyorrhea alveolaris, but let me emphasize the fact that dentists use iodin too freely on the gums. A little pain here, or a little infection there, and the gum is injured by repeated applications of iodin. We know the value of iodin as a counterirritant or as a germ destroyer. We also know that it destroys the vitality of tissues, and many a gum has been burned and blistered, and inexcusably made a region for more infection. We should remember that there are always germs in the mouth, many of them harmless, but also many ready to attack a broken mucous membrane or ready to be absorbed into the system through such a lesion. Therefore, care should be exercised not to injure the mucous membrane of the mouth or gums, especially when an infection is being treated.

I find that infected teeth and tonsils are frequent causes of thyroid disturbance, causing both hypersecretion and hyposecretion, and no medicinal treatment will effect a cure until the foci of infection have been removed. The absorbed toxins produced by the germs of infection and by the local suppuration often act peculiarly on the thyroid gland. The thyroid may be considerably enlarged, yet may give absolutely no symptoms of increased secretion and need not be cystic. Something irritates the gland, and then something else inhibits the result of its increased activity. This is shown by the surgical removal of the source of the mouth infection, and sometimes marked symptoms of hypersecretion immediately occur. I have seen three such instances. In one case the gland became greatly enlarged after the operation, exophthalmos occurred, and a tachycardia of from 140 to 160 developed. Before the operation, absolutely no thyroid symptoms were present, except a slightly enlarged gland.

Not only the thyroid, but many other internal secreting glands of the body, are disturbed by the absorption of germs or toxins from the mouth. The suprarenals are, probably, especially acted on, as we have great changes in blood pressure in these patients. Many a patient with a very high blood pressure shows no arterial and no kidney excuse, no intestinal toxemic excuse, and this high pressure persists, even when the diet is made rigidly vegetarian. Consequently, it is self-evident that there is internal secretion disturbance. Whether the suprarenals hypersecrete, or the thyroid, and one or two other glands perhaps undersecrete, it is difficult to determine, but that these glands are disturbed there is no question. Also there are many instances of very low blood pressure in these patients, and again we may not know whether the toxins depress the nervous system, or the vasomotor center; or whether they stimulate the thyroid to increased secretion of vasodilator substance, or inhibit the suprarenals as to their vasopressor substance.

Not infrequently patients with glycosuria have mouth infection. These cases are likely to be without typical diabetic symptoms, namely, without polyuria, and without thirst. In these cases there may be pituitary disturbance, or suprarenal disturbance, or pancreatic disturbance, or the glycosuria may be caused by the absorption of something that interferes with the liver or with muscle metabolism.

We must recognize that germs may be present in and around gums, allowing dangerous absorption of their toxins, without any local manifestations of pus. This is true of some germs that cause arthritis.

Again, there can be no question that the constant absorption of irritants or poisons from the mouth can cause irritation of the kidneys and subsequent chronic nephritis, even if focal infection of the kidneys is not thus caused, and many a case of autogenous infection or purulent infection of the kidney occurs without any apparent tangible excuse. Probably these obscure cases occur mostly from concealed infections of the mouth, tonsils or one of the sinuses adjacent to the nose.

We do not know that this continued absorption of concealed irritants in the mouth for months and years may not cause arteriosclerosis. All sorts of gastro-intestinal disturbances, such as hyperacidity and ulcer of the stomach, can be caused by such mouth infections. And let us remember that cancer of the stomach seems to be on the increase. Recently I saw in consultation a patient who made a profound impression on me. He was a man but little over 40, who had, before it was discovered, far advanced, inoperable cancer of the stomach, and besides several bridges, there was hardly a tooth in his mouth that was not crowned. He had been fussing with his teeth and visiting dentists for fifteen years or more.

Statistics prove that cardiovascular-renal disease is increasing enormously, and we know that, in the last twenty-five years, crowns, bridges and pivoted teeth have also increased in a most extraordinary fashion. One has only to look into the mouth of every patient who enters one's office, of every patient who enters the hospital or the dispensary, to see how hard the dentists are working.

One of the saddest things that can happen to a person is infection of the blood with the *Streptococcus viridans*. This germ probably always gains an entrance through the mouth, and if we should cultivate the pus and secretions from the patients who have diseased mouths, we should probably be astonished to find the number of times the *Streptococcus viridans* was present. In the vast majority of cases the only hope for the patient with *Streptococcus viridans* is to eradicate it from the mouth before it infects his blood and causes malignant endocarditis.

The relation of mouth germs to arthritis deformans seems proved, hence eradication of the source of infection before the joints are affected should be the preventive treatment of today. To allow infection in the mouth to persist until this painful and crippling disease develops is inexcusable.

For nearly two years now, at a public tuberculosis institution of which I am chairman of the medical board, we have examined the mouths, corrected the teeth and removed sources of infection of every patient who entered the institution, and owing to this preventive treatment we have had less tonsillitis, fewer sore throats, less indigestion, and less influenza and colds than we had before we began these mouth investigations.

I think that both dentists and physicians have been very slow in discovering the harm done to patients by crowns and bridges, by leaving infected teeth in place, and by improperly filled teeth. Physicians do not pay proper attention to, and many times do not even look into, the mouths of their patients. I look back with chagrin and shame as I think of the probable cause of the chronic invalidism of some of my patients of years ago. But with this admission of neglect in the past, I deplore the present necessity of being compelled to fight with both the patient and his or her dentist for the removal of infected foci in the mouth. The dentist frequently will not cooperate. He naturally dislikes to remove his own fine handiwork. Hence, I repeat, when a bad tooth comes out, or a dirty crown comes off, let the patient, or, if he is anesthetized, his nearest relative, smell of it. This is an educational propaganda.

CONCLUSIONS

1. Most unexpected tolerance to pyorrhea alveolaris and to tooth infection is found.
2. Chronic invalidism may be caused by mouth infections.
3. The blood pressure may be raised or lowered by mouth infections.
4. The thyroid gland is frequently enlarged, and may hypersecrete or hyposecrete, in these infections.
5. Serious disturbances of the blood, heart, kidneys, stomach, intestines and joints are frequent from mouth infections.
6. Glycosuria can be, and perhaps true diabetes mellitus may be, caused by mouth infections.
7. Serious distant focal infections may occur from mouth infection.
8. Serious brain and nerve disturbances, as well as neuritis, may occur from mouth infection.
9. Ulcer of the stomach, pyelitis, appendicitis and chronic colitis may be caused by pyorrhea alveolaris and mouth infection.
10. Pneumonia, especially that which follows influenza, may frequently be caused by pneumococci long carried in the patient's mouth.
11. No treatment of these conditions will be of any avail until the mouth is made clean.
12. Stock or autogenous vaccines are not very promising as to their therapeutic value, but in obstinate cases they should be tried. Therefore, it is generally well to grow a culture from the infection in the mouths of these patients, that autogenous vaccines may be made and used, if desired.
13. One should be very careful not to promise a cure of a distant condition, although that condition was caused by the mouth infection. However, many brilliant cures are caused by surgical eradication of infected areas. The patient should always be told that the surgical removal of the infected area in the mouth does not remove the germ localized in distant parts of the body, nor does it immediately cure an inflammation caused by these germs in a distant part, nor will it restore degenerated tissue, but it will remove the primary source of infection.
14. It should be urged that any fresh lesion of the mucous membranes of the mouth is a source of danger, much as is a lesion of the skin. The efficiency of the integument in warding off disease germs has long been recognized. It should be recognized that fresh cuts, abrasions, and blistering of the mucous membrane of the mouth with iodin, or other strong escharotics, offer the opportunity for the absorption of germs that may be freshly received into the mouth, and more especially of germs already in the mouth.

MIGRAINE AND CHRONIC INTESTINAL STASIS

THEIR RELATIONSHIP AND TREATMENT

MAX EINHORN, M.D.
NEW YORK

By migraine is meant a condition characterized by severe attacks of headache that occur at varying intervals, with periods of freedom between the attacks. The headache is usually followed by vomiting, either of plain gastric fluids or contents, or of bile, "bilious vomiting." After vomiting, the patient usually feels better, the attack gradually subsides, and there is an interval of freedom from the trouble for a month or two, or it may be for only a week.

The term "intestinal stasis" was first applied by Lane to a condition in which there is a delay in the onward movement of the intestinal contents, accompanied by symptoms of a neurotic type. Formerly, instead of intestinal stasis we spoke of habitual constipation. In constipation we find occasionally a great number of nervous symptoms — dizziness, lack of concentration of the mind, insomnia, etc. This combination of nervous symptoms and delay in the onward movement of the intestinal contents and action of the liver is considered by Lane as "intestinal stasis"; by others, the same picture is designated as "constipation with nervous phenomena."

SYMPTOMS

In migraine it is characteristic that the headache comes on suddenly, in the midst of perfect health, although there may be a premonitory stage of short duration. Sometimes the headache is followed by a defect of vision; some persons have a glimmering light in one eye, or they cannot see well with one eye; the headache is usually in one part of the head. That is why it is called migraine, from the Greek hemicrania (on one side of the head). The headache is usually quite severe, so that the patient cannot work and may have to go to bed, and with it there are disturbances in the upper part of the abdomen, followed by nausea and vomiting, and if there is nothing in the stomach then ultimately bile comes up. After vomiting and purging, the patient feels relieved, and there may be a period of freedom for quite a while.

Patients with migraine may be in good condition and apparently perfectly well; or they may belong to a group which suffers from enteroptosis and weakness, and are thin, anemic individuals. They do not feel well between the attacks, they cannot work much, their appetite is not good, and they are constipated; but these complaints are of minor degree and do not incapacitate them. Among the abnormal conditions may be some disturbances of the vision, or disturbances of the abdomen or of the genito-urinary organs.

In chronic intestinal stasis or simple constipation with nervous phenomena, the bowels do not move well without resort to some aid. Besides the constipation, the patients also complain of a variety of symptoms, sleeplessness, headache, etc. The headaches are not severe like those of migraine, but are mild and come on almost daily, particularly in the morning. Then there may be slight dizziness, and the patient cannot concentrate his mind and cannot do the same amount of work as formerly. His appetite is poor; sometimes there is nausea, and sometimes there is a fear of going out alone or of going to church. These nervous phenomena may be exaggerated; sometimes the constipation is associated with melancholia. That is not an infrequent combination. Constipation exists also in a high degree in the insane.

In regard to the connection of these conditions, some physicians say that constipation is at the root of these troubles, causing even insanity. I myself do not believe this, but rather think that commonly the reverse is true, namely, that persons who are nervously upset and are insane have their constipation increased by their nervous condition. I once saw an insane patient with an immense very hard tumor in his abdomen that could not be differentiated from a large neoplasm. When it was learned that the bowels had not moved for a week or two, it was easy to make the diagnosis that it was a fecal mass. He was given a strong cathartic, the bowel was washed out for a number of days, and the tumor disappeared; but the patient's insanity was not cured. Although the constipation was relieved, the insanity persisted for a whole year, when the mental symptoms cleared up.

ETIOLOGY AND TREATMENT

French writers have given us the theory of autointoxication. Bouchard was the first to advance the theory that poisons form in the body which give rise to these disturbances. Any organ which is at work creates waste products which are, so to say, deleterious to the system, provided they stay there. Usually the system eliminates them. If one does manual work, the muscles use up some of their material and produce also waste products. Naturally, these waste products are removed, being eliminated during the period of rest, so that no disturbances originate. It is the same way with all the organs of the body. In the brain, for instance, reading or writing creates waste products, just as in any machinery; there is a by-product that has to be eliminated. Our organs are so arranged that the body normally is easily rid of these waste products, and no symptoms arise.

If we go a step farther we can see that if the required period of rest is not given, if the work is kept up too long, the waste products accumulate in a greater degree, and they are not eliminated in a complete manner. For instance, if a person can work six or eight hours every day and his organism is so arranged that he can rest in nine or ten hours, and he then works for twelve hours a day and does not get the required rest period, the system does not get the needed rest, and disturbances arise.

These disturbances may be considered as the defensive mechanism of the organism. To apply this theory to migraine: If there is a mental strain going on in some way, the patient doing too much work, reading or dancing, or taking part in too many social happenings and not sleeping or resting enough, the brain does not get sufficient rest and does not have time to regain its normal condition. Some waste products accumulate, and every day there is an increase in their amount, so that ultimately there is a catastrophe. The body tries to create something that will compel the organism to rearrange matters, and there is a spasm of the blood vessels on one side of the brain which makes itself felt as a hemicrania. The patient has a headache due to that spasm and has to lie down and rest more; during this time the restoration of function of the brain is completed in a normal way, and elimination takes place. The headache is then relieved; a relaxation of the blood vessels takes place and reestablishment of equilibrium ensues.

Elimination can be helped by emptying the bowel. The eliminative organs are the kidneys, skin, lungs, liver and digestive tract. The waste products are first taken up in the blood. How does the brain, for instance, get rid of the accumulated waste that must first be taken up by the blood? The veins do their share first. Part of that blood goes to the liver through the arteria hepatica. I do not speak here of the portal vein. The latter lies there as the barrier to prevent anything from passing through into the blood which comes directly from the digestive tract. But outside of that the other blood — only a part — goes to the liver. That brings something for the liver to work on; but the digestive tract has also the power to eliminate. Now, if the patient takes a cathartic or vomits, a part of the accumulated waste products is eliminated. The gastric juice is not only a secretion but also an excretion; it is excreted through the stomach. Sometimes urea can be excreted through the stomach, and still more through the liver. The bile brings down the excretory substances of the liver and empties them into the intestinal tract. If a patient has a migraine and we give him calomel, he has a greater flow of bile and the elimination is increased, and vomiting and purging clear out the system.

In the autointoxication theory in intestinal stasis, it is quite different. Fecal matter contains decomposed material and innumerable bacteria. The idea that poisonous substances reach the organism from this source is at first thought plausible. But normally the digestive tract (including the colon) does not take up any poisonous material. The mechanism of the system is so arranged that its work shall be kept up, and the colon is so constructed that the fecal matter can be discharged without much difficulty. Many physicians are imbued with the idea that if the intestinal contents remain too long in the system they will give out to the system poisonous substances which create all the symptoms before mentioned, and that we have to deal with an intestinal autointoxication.

If this theory can be worked out without awakening too much fear in the mind of the patient, it will not do any harm; but if it is exaggerated, great harm may be done. This point must be emphasized, for it is of importance. Lane said that if there is some delay in the motion of the contents of the bowel — and this is especially true in cases of enteroptosis when there is a prolapse of the colon and an irregularity in the position of the colon, which creates an autointoxication — this is the cause of the troubles associated with constipation, as sleeplessness and headaches, and also of many other ailments, such as chronic rheumatism and gout.

This theory has been overestimated, and has taken such root in the minds of some physicians that if they see a patient who is constipated they think he must be told of it. "Why, you cannot live that way, with poisoning going on in your system all the time; if that keeps up, all will come to an end." The patient goes home and worries, and doesn't know what to do. He tries to do exactly what the physician tells him. He eats no proteins, but does not feel much better. He comes back to the physician, who says: "Your trouble is in the colon; the colon is not exactly right. It is too long. Instead of going in a more or less circular way, it forms angulations and drops down, and that is wrong. There is a delay there, and that is where the trouble lies." If the patient does not get better within two or three weeks of treatment, operation is suggested for the purpose of shortening the colon, cutting out part, or perhaps the whole of it, performing an ileosigmoidostomy or a colectomy.

Were this theory really correct and could we prove it, we might at least try such a procedure; but in reality such patients feel much worse after operation. A great many are made worse, and some have died as a result of it. In order to demonstrate that we really have to do with an autointoxication, we ought to be able to produce the poison by experiment and then to inject it into animals and show that that poison causes these symptoms, not in one or two instances, but in every instance. If that could be proved, we might speak of it; but it has not been proved, and much harm has been done by teaching it, in making people afraid of themselves, making them afraid to eat and afraid of their digestive tracts, especially of the large bowel which, according to their minds, is a place of poisoning.

It is just the reverse. The colon is our best friend. Instead of being a place of poisoning it is a place in which things can be kept without harm and later on eliminated. It serves a very useful purpose. It can take good care of the excrement and can work it up better. If we lose the colon, we are much worse off than with it. I speak from experience, for such persons come to me almost every day worrying about their large bowel.

This is all wrong. Unless there is some organic disease in the bowel which gives rise to ulceration, for instance, in such a way that it is exposed to the absorption of fecal matter — and such instances are very rare — the mere presence of fecal matter will do no harm, for so long as the mucous membranes are intact, no matter what the shape or position of the colon — big or little, up or down — no surgical intervention will be required. The latter will be reserved for organic diseases (strictures, or partial stenosis by bands, etc.).

In regard to the connection between the nervous phenomena and constipation: In a great many cases, the nervous phenomena do not originate from the constipation. This has been proved by Dunin of Russian Poland. Two important points can be brought out to demonstrate this. Constipation can be established for a number of days by giving a patient opium, and yet he will be perfectly well, showing that the fecal matter does him no harm. If a patient with these nervous phenomena — sleeplessness, distress, etc. — is given a nerve remedy, say 15 grains of bromid, a movement of the bowels will at times take place without a cathartic. This will not be true in all instances, but will in a great many, showing that the primary factor in the condition is the nervous state of which the constipation is the consequence.

It is important to know that fear and constant anxiety about having a movement is bad for the patient; it makes him worse. The more he is frightened and made anxious about having the movement, the worse is the constipation; the fear and anxiety exert an inhibitory influence on the peristalsis.

TREATMENT

In cases of migraine, we first have to look into the condition of the system and find out any existing faults, such as astigmatism, which should be corrected by proper glasses; enteroptosis, by giving the patient a bandage; chlorosis, anemia, by building up the system and getting the patient into a normal state. For, if the organism is below par, anomalies will develop much more quickly, and the migraine will come on more readily than if the body is in good condition. The first thing to be done is to try to adjust any existing anomalies of the body.

During the attack, the desired rest must be secured for the patient; if possible, in bed. No nourishment should be taken, or only very little liquid food; and a mild aperient or a saline enema should be given. If these measures are not sufficient, citrated caffein, 2 grains, in conjunction with pyramidon, 5 grains, may be administered twice daily. In rare instances, codein or morphin may be required. All of these remedies act well and should be given as needed. Calomel is good and can be administered when indicated, and injections may be given to wash out the bowel. In a day or two the migraine is over and the patient returns to normal, and then we decide about other measures to adopt to prevent, if possible, the return of the migraine. If we succeed in eliminating all the causative factors, the migraine will not reappear; but if we cannot do that we can at least cause the attacks to be milder and less frequent.

In habitual constipation, or intestinal stasis with these nervous phenomena, it is of first importance to reassure the patient by telling him that in case he is constipated no harm has been done to the system. We must take away the fear of poisoning. The patient should be told to eat, but not to overwork, and his bowels will move all *right*; also to go to the toilet every day at the same hour, in order to reestablish the habit that has been lost.

In many patients constipation is due to a one-sided diet, and they have to be taught a proper diet. They should be urged to eat plenty of bread and vegetables and fruit, and plenty of salads. The more indigestible food these patients take, the better. It increases the activity of the digestion and augments the peristalsis. If they are given food that will digest readily there is too little work for the bowel to do. Many patients take too little water. These should be encouraged to drink more water, since drinking water between meals increases the action of the bowels.

If all this has been done and it is not enough, the question arises whether we are justified in giving the patient cathartics. Mild aperients are rational. If the patient does not do well enough with dietetic measures, we must resort to other means. There is no harm in them; also sedatives, as already mentioned, should be given. As mild cathartics, I would consider cascara sagrada or tincture of rhubarb, 15 grains twice a day; also small amounts of licorice powder. These remedies can also be employed in combination with agar-agar. Agar alone is sometimes sufficient. It is a substance which takes up fluid and does not give it up readily, but retains some of it. Constipation is sometimes due to the stool being too dry. The water has been taken away by the digestive tract, the excrement is too dry, and the peristalsis cannot push it along easily. Therefore, if agar is given, which is not digested in passing through the tract, it takes up fluid and lubricates the fecal matter and gives it a more moist character and appearance. It is helpful to the bowel and eases the movements, so that it can be given in large quantities. But often this is not enough, and the combination of a mild cathartic remedy with it is beneficial. The idea of using the cathartic remedy in this way is that instead of being absorbed in the stomach it is carried along farther in the tract. The agar has the advantage that if the remedy is incorporated with it, the remedy does not act too quickly but emerges slowly along the entire digestive tract by the process of osmosis. That is why these mild cathartic remedies incorporated with the agar act so much better than either alone. In this way one can give phenolphthalein-agar or rhubarb-agar with great benefit. The principle with all these remedies is that instead of increasing the quantity the patient should be told to take a little less gradually from day to day or week to week, so that ultimately he may not need to take anything; but if the patient does not succeed in this, there is no harm in taking a little once in a while.

No one should be operated on for these conditions unless there is some organic lesion present. If there is a stricture of the colon there are sometimes fever and vomiting, and an operation may be required; but not with these symptoms of plain, habitual constipation. In such cases an operation is not justified. I well know that my remarks conflict with the views of others. These are my views, and I assure my colleagues that my experience leads me to state that they can relieve without operation their patients suffering from constipation.

In treating patients with habitual constipation, saline enemas may be used, and olive oil injections may be given. The latter is especially good in spastic constipation, when the fecal matter is hard and dry. An injection of from 5 to 7 ounces of olive oil may be given, and left in the bowel over night. This treatment may be continued for two or three weeks every night, and then it may be given every other night for a few weeks. That is apt to cure the patient. Klemperer has given water instead of oil with good results, but the oil is better. It is not necessary to give these injections too high up. It is well to have the patient lie first on the left side, and during the night it will flow in. The olive oil should be used at blood temperature.

All these measures are more or less reassuring to the patient, and act subjectively as well as directly.

Liquid petrolatum is also good, but in many cases in which it does not act, agar gives a satisfactory result.

THE INDUSTRIAL DISPENSARY IN PREVENTIVE MEDICINE *

S. M. McCURDY, M.D.
YOUNGSTOWN, OHIO

Civilization must progress by means of ideas and ideals, and as a protest against any existing order of affairs an idea must take root in some one's mind. For the acceptance of an idea, if it is to be useful, the public must realize its necessity, since necessity is the motive power of all progress. We have repeatedly listened to statistics indicating the cost of waste produced by preventable illness, but now, as never before, we realize the importance this question has for our nation. Man power conserved now, both in civilian and military life, assumes such an important place in our preparedness schemes that all agencies must be employed for the conservation and protection of our people.

We have never been satisfied with our preventive medical work, and never can we be until we enlist new forces for the cause. We have placed our faith largely in police power, and have educated our people in spite of themselves to mass for community protection. We have never, through our spasmodic periods of medical education, enlisted the cooperation of the individual for his own protection. Witness the fact that, in spite of police power, our city streets are covered with salvia, and remember that it is so because individuals have not recognized the danger. Remember the work accomplished by our campaign against tuberculosis, and do not forget that in most communities many do not receive an early diagnosis because of (1) inability to purchase the services of a good physician, and (2) ignorance of the necessity for medical care.

How many cities or states can boast of having set aside beds enough to care for their tuberculous patients? How many can show me that they do not harbor tenements that are breeding places for tuberculosis? How many boards of health will tell you that all the physicians are making prompt and accurate returns of their preventable cases? Individuals must be medically educated. They must develop a medical conscience before greater results can be obtained. We have discussed the increase in heart and kidney lesions, and pointed out their early mortality, which we say represents the wear and tear of life. In any given industry do we know what a physiologic day's work is or have we arrived at the length and amount of a turn at labor by noting what the average can stand for a given space of time.

Within a very few years we have seen our preventive work take a turn for the better. In regard to children, we have recognized the fact that education is worth little without health. We know that many parents either through ignorance or wilfulness send children to school who are suffering from contagious diseases that are dangerous to others; hence the rise of school inspection, with all its benefits. We learned soon that many physical handicaps could be removed and before long parents were willing to aid in the medical school work. We presently found that some children must be placed in a selective school environment, lest their deficient mentality should ruin others. We taught our educators that children could have

* Read before the Section on Preventive Medicine and Public Health at the Sixty-Eighth Annual Session of the American Medical Association, New York, June, 1917.

incipient tuberculosis and still be educated in open air rooms without danger.

Up to within a few years ago we assumed that the man grown child, brought up without school inspection, was able to care for himself. Today we know that he has not the medical knowledge, that he is careless about his health, and that his employer often asks him to work in a place that we know is detrimental to well-being. Some industrial organizations have recognized the economic loss due to preventable illness, and are meeting the conditions with industrial dispensaries. No movement of late years holds out so much promise to preventive medicine as do these diagnostic clinics and clearing stations. Here is joined together the sum total of the health of workers and the world's production. Here is introduced into industry a spirit of humanness that is beneficial to employer and employee. Here we have a compulsory medical education for those who need it most. In this movement we shall realize the actual national asset that we must have in order to insure a country prosperous because of healthy human workers.

Industrial dispensaries demand for their success two fundamental principles:

1. Men must not have preventable illness, whether due to their own or to their employer's neglect.
2. If sick, they must be returned to work in the shortest possible time with a minimum of permanent impairment.

These diagnostic clinics have grown by leaps and bounds. Some are doing most excellent work, while others are more or less in the formative stages. We should unite on a desired program, and then from all parts of the country drive home to employer and employee this great entering wedge which will open up the way to a better knowledge of preventive medicine. Business men will recognize the necessity for medical supervision, for it promotes greater efficiency and makes for economy. They will eliminate the cause within their gates as soon as medical men show them the way. The individual and society must recognize the moral obligations resting on them and do away with those causes of illness for which they are to blame. Industry will assume the cost of dispensaries until the people can be educated to bear their own share of the burden.

Dispensaries for accidents are already a recognized obligation on the part of industry, and dispensaries for sickness soon will be introduced. The best work in this field can be accomplished by the recognition of a few fixed principles and a definite program:

1. All men working in the various industries should be physically examined.
2. All new applicants for work should be physically examined.
3. All employees should be reexamined at stated intervals, and their previous condition checked. A system should be introduced by which all men leaving work because of illness, or returning to work following illness, are compelled to go through the dispensary.
4. Educational work should be carried on among the men by means of talks, pamphlets and moving pictures.
5. The dispensary should be so equipped that it can treat minor illnesses and act as a diagnostic clearing house.
6. To insure adequate medical attention a system of insurance should be installed, the expense to be borne by employer and employee.
7. Visiting nurses should follow the patient to the home, aid in nursing care and give health and household education.
8. Later, industry should employ its own physicians to treat illness in the home, exactly as it now does in accident cases.
9. Dental dispensaries should be organized as rapidly as possible.
10. Defects in old employees must be remedied free of charge whenever possible.

Under such an organization one will insure:

1. Adequate medical attention.
2. Minimum amount of permanent impairment.
3. Diminished loss of time owing to absence from work.
4. Diminished waste due to loss in production. Lessened numbers of green men hired and increased wages to the individual worker.
5. Happier people and pleasanter industries.
6. Collection of data on the hazards of a given industry at a point most useful.
7. A real work and contribution to the cause of preventive medicine.

That such an organization is possible and can produce such results has been proved by many industries. Several firms have, on the one hand, constantly reduced tuberculosis, as their work progressed, and, on the other hand, they can show men at work in whom the disease has been arrested.

There are firms that can positively show a decreased labor turnover, and the acknowledged cause is their dispensary. Many firms have long lists of defects remedied, some pertaining to the eye, some to general diseases, and some to deformities acquired or inherited. Any number of industrial physicians can tell of the benefits of the industrial diagnostic dispensary as shown by less time off duty and by the awakening of the community to health needs.

But our work is not limited to treating sickness after it is acquired. We supervise all phases of sanitation within the plant. Water is constantly tested to see that it is proper for drinking. Water closets are arranged so that they may be sanitary. Washing facilities are installed. Work places that are insanitary whether owing to poor heating facilities or to excess of dust, poor light, poisonous gases, etc., are improved by mechanical means. Problems pertaining to hours of work and the relation of fatigue to health are being solved and will eventually be placed on a scientific basis. Rest and nutrition become a branch of the industrial physician's work, as well as all matters pertaining to the well-being of an employee.

Let us be honest pessimists and look facts in the face. Under the present system of the practice of medicine, two conditions occur. A large majority of our workers are not receiving adequate medical attention, with the natural result that there are many unnecesary days' absence from work and many permanent deformities. The science of preventive medicine has not progressed as far as is possible with industry enlisted in the cause. While I am a firm believer in the principle of health insurance and participation therein by the state, I know that the time is not yet opportune. We must go ahead with our industrial dispensaries, and they will show us the way to our dream, national compulsory health insurance.

243 Norwood Avenue.

ABSTRACT OF DISCUSSION

Dr. George M. Kober, Washington, D. C.: It has been well said that the highest aim of scientific medicine is the eradication of preventable diseases, and that the health of the people is the highest law. Now, if these are axioms, the question arises, What shall be done to secure the most beneficent results? It is evident that the solution of the problem can scarcely be left to the practitioner alone. The man who has equipped himself primarily for the cure of disease can hardly be expected to give his utmost effort to the prevention of disease. I believe that the protection of industrial workers in all its broad aspects, including the industrial dispensary, is a public health function and clearly a duty of the state, and I am glad that some of our health departments—notably that of New York City—have assumed this function.

To get the best results it is necessary that there should be a corps of medical workers in the employ of the state whose primary function is the prevention of disease; a body composed of men who are not only only well trained in every department of medicine, but more especially in preventive medicine. Such men will not only render valuable service in the prevention of disease and accidents, but can be relied on to restore as speedily as possible the earning capacity of the wage earner. All this work should be done at the expense of the state or community. It will be found that large sums of money will be saved in preventive efforts. Moreover, it should be remembered that in the ultimate analysis the taxpayer pays the bills incurred as a result of sickness, accident and permanent disabilities in the majority of wage earners. The sooner we work to that one end the better it will be for humanity.

Those men should be full-time medical officers and should give evidence of proficiency, not only on admission, but should be subjected, every five years, to reexaminations to determine their fitness. Naturally, such a corps ought to be absolutely free from politics, and quite as independent as the Medical Corps of the Army, Navy and Public Health Service. When this is accomplished I believe we can look forward to really beneficent effects, and there is certainly hope in that direction. I realize that in spite of certain discouragements there is a growing interest in preventive medicine, as evidenced by the ever-increasing attendance in this section.

THE RÔLE OF THE TRANSVERSE MESOCOLON FOLLOWING GASTRO-ENTEROSTOMY

C. A. ROEDER, M.D.
OMAHA

A gastro-enterostomy is no exception to the rule that it is impossible to short-circuit completely any portion of the gastro-intestinal tract unless a complete obstruction is present. However, if the operation is properly performed the irritating gastric juices are drained off as fast as secreted, affording Nature an opportunity to heal the ulcer. She ejects the food when ready through the most convenient opening. It is now definitely established that we obtain equally as good results whether or not the pylorus or duodenum is blocked, and that we obtain better results for gastric ulcer when the ulcer is destroyed by cautery or excision, the former method being preferred. The good results are attributed by many to the presence of the alkaline bile and pancreatic juices in the stomach neutralizing the acid. This makes it quite difficult to explain why a duodenal ulcer becomes chronic when we know that from its beginning it is almost constantly bathed with these alkaline fluids. We have no proof that practically all duodenal ulcers do not become chronic. Not infrequently, an entero-anastomosis is performed below a gastro-enterostomy, and with this procedure, as in the Roux Y operation, none of the bile and pancreatic juice is carried to the stomach, yet our results are equally as good as when a simple gastro-enterostomy is performed which allows free interchange of fluids.

Directly opposed to the therapeutic theory, many consider the presence of these fluids in the stomach as the cause of our poor results of varying degree, particularly vomiting. Various experiments and case reports, however, have settled this controversy, particularly the three cases reported by Collinson and Braithwaite,[1] in which the duodenums were resected for disease with a closure of the proximal and distal ends, forcing all the duodenal contents back into the stomach and which left the latter by way of an anastomosis. With all plastics on the pylorus and duodenum and simple gastro-enterostomies there is a free interchange of fluids; while with the Polya operation there is a common vesicle formed by the jejunum and stomach. Gerster feeds bile by tube from a wasting biliary fistula with good results.

There is no definite proof that the presence of these fluids in the stomach has any beneficial or harmful effect on gastric and duodenal ulcer. The duodenal contents evidently play a negative rôle, and nearly all patients explored properly for persistent vomiting or indefinite distress following gastro-enterostomy have shown a deficient drainage of the stomach, duodenum or afferent jejunum if a secondary ulcer is not present. Our results correspond to the perfection of the mechanical features of the operation. With gastric ulcer it is assumed that the ulcer is destroyed by cautery or knife.

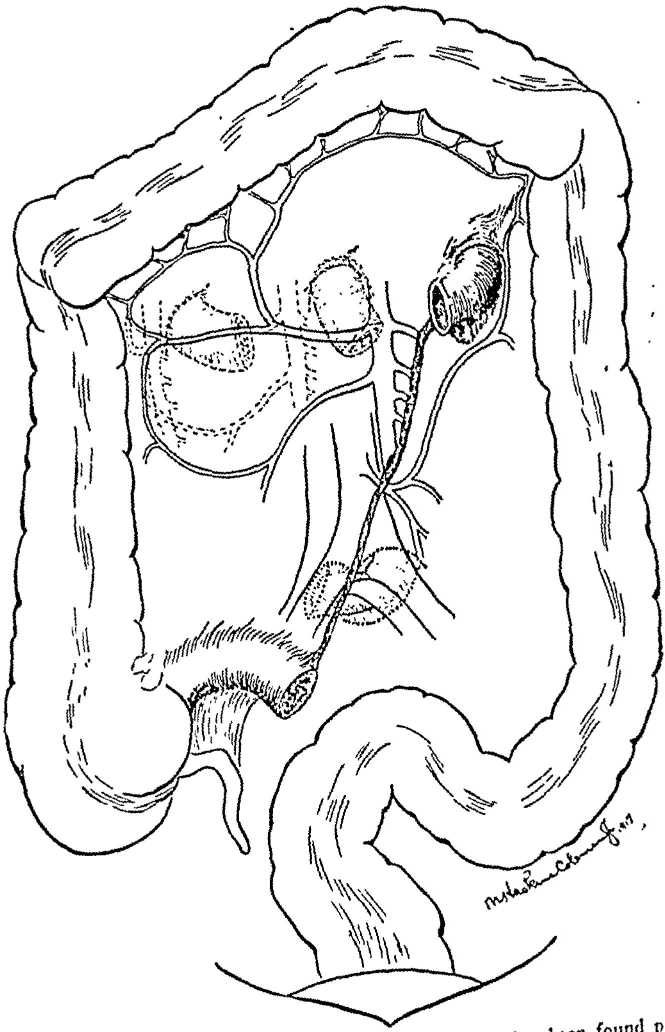

Fig. 1.—The various points at which the jejunum has been found projecting into the greater peritoneal cavity.

In performing a gastro-enterostomy we are joining two organs of opposite function. The stomach is a reservoir, the muscular action of which is activated by its secretion, emptying itself through a relatively high opening. The duodenum and first jejunum comprise a rapid transit duct as shown by fluoroscopic examination. In performing this operation it is essential that the stomach and duodenum are freely and constantly drained into the efferent jejunum by way of the anastomosis, and any interference at any point in the performance of this double rôle will bring on varying degrees of imperfect results. Following all gastro-enterostômies a small percentage of patients vomit for a short time, later going on to complete recovery. This no doubt is due to a moderate kink, gradually adjusting itself.

---

[1] Collinson and Braithwaite: Brit. Jour. Surg., 1913-1914, 1, 665.

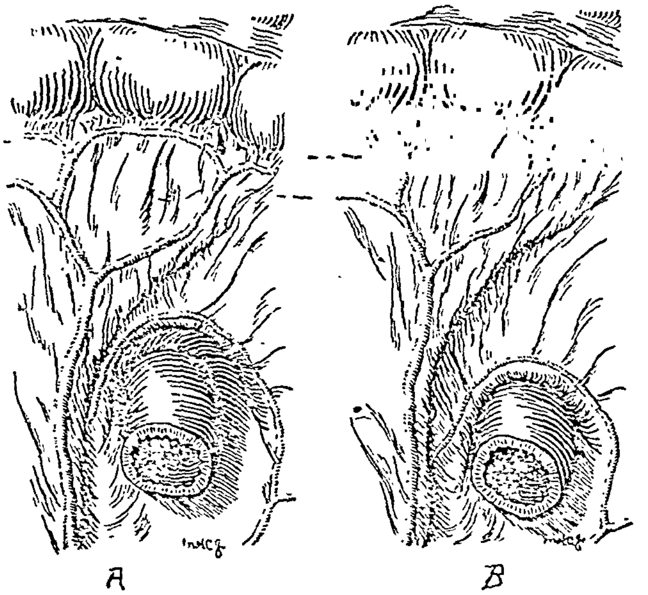

Fig. 2.—*A*, a space between the superior duodenojejunal fold and the flexure forming the superior duodenojejunal fossa; *B*, this fold attached to the bowel with no fossa present. The vessel along the edge should be noted.

The stomach enjoys considerable excursion and the anastomosis lies sharply above the only fixed point in the gastro-intestinal tract involved. Following the operation the stomach tends to assume its normal position, retracting upward, and if dilated at the time of the operation will generally contract afterward, further increasing this upward pull. With these three factors present, namely (1) excursion, (2) retraction and (3) contraction, it becomes necessary to note the point of origin of the flexure and the amount of its fixation.

The Mayos unite the mesocolon to the stomach just above the suture line in order to prevent an intraperitoneal hernia and to help form a funnel-shaped depression in the stomach for drainage. In addition, this attachment no doubt retards the active excursions in all directions, thus preventing angulations in the proximal jejunum. The portion of the stomach surrounding the anastomosis is held firmly enough to prevent an upward pull, which, if present, might kink the afferent jejunum beneath the edge of the mesocolon and at the anastomosis, as happened in Mumford's case.[2] This attached mesocolon acts as an anchor.

The Mayo method conforms to all the best mechanical principles which are so essential to the success of this operation. It unites the jejunum right to left as near the fixed point (flexure) as possible to the lowest point of the stomach, which is opposite the cardiac orifice. Occasionally, however, the jejunum comes through the mesocolon farther to the left than usual, and in such instances the jejunum is better united from left to right in order to prevent angulation in the proximal jejunum at the anastomosis and flexure. With the opening placed at the lowest point, the ever-present gastric juice is constantly and freely drained. This free drainage prevents the painful gastrospastic wave which has been shown by Carlson to be the cause of considerable distress. The stomach then loses its hyperperistaltic stimulant, and even lapses into a temporary atonic state, as demonstrated by Wilensky.[3] The Hartman method of connecting the jejunum to the pyloric portion of the stomach has not produced the results expected. The opening is placed in a sphincteric area which has a tendency to close it. It is also placed too high and too far to the right, which does not allow constant and free drainage. It has a greater tendency to angulate the afferent jejunum.

If the mesocolon were not present, and the duodenum and first jejunum were on a free mesentery, gastro-enterostomy would be much simpler. As it is, we have a portion of the bowel (the flexure) fixed to a varying degree to the posterior abdominal wall. This fixed point acts as a potential angle and also tends to keep the flexure at a lower level than the anastomosis.

ANATOMY

The usual origin of the jejunum is at the dorsal border of the mesocolon, opposite the left border of the second lumbar vertebra. This point may vary and may be any place between the hepatic[4] and the splenic flexure (author's case), and if farther to the left than usual it may indicate a left to right anastomosis. We must look on the duodenojejunal flexure as a *fixed*

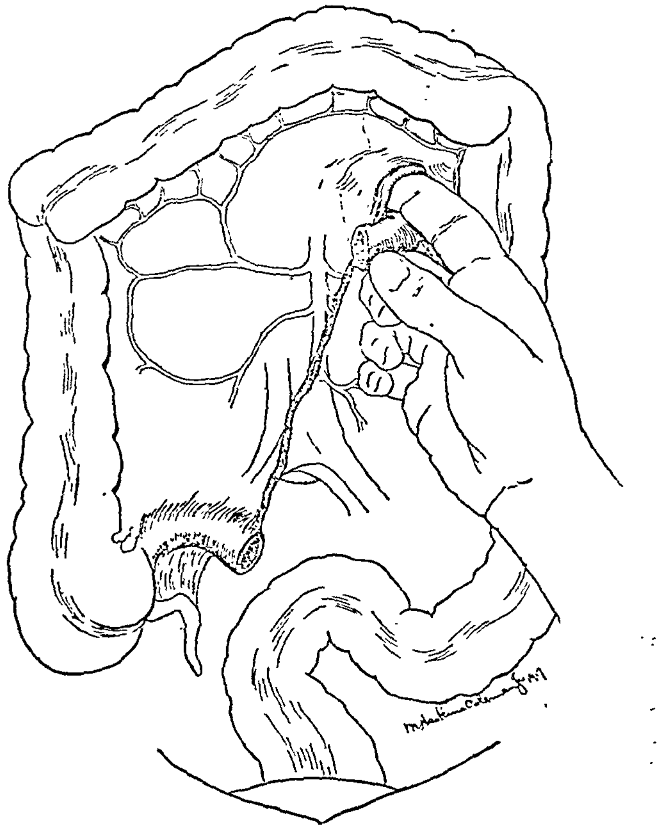

Fig. 3.—Finger inserted beneath the fold to determine the degree of constriction. Higher up the amount of fixation of the duodenum by the plica duodenojejunalis and the ligament of Treitz can be determined. It should be noted that the last two are not seen at operation.

---

[2] Mumford: One Hundred Surgical Problems, Ed. 1, 1911, p. 22.

[3] Wilensky: Ann. Surg., June, 1917.

[4] Boyd: Brit. Med. Jour., Sept. 19, 1914.

point with an active duodenum above (Alvarez) and a free jejunum below. This flexure is held fast by three structures, two described by Crymble,[5] and the third, which is not constant, observed by myself. Crymble has shown from dissection that the ligament of Treitz and the supramesocolic portion of the plica duodenojejunalis extend from the anterior surface of the flexure to the posterior abdominal wall, thereby limiting markedly the mobility of this portion of the bowel. These structures lie above the mesocolon and are never seen at operation.

Another point of occasional obstruction I have observed is where the superior duodenojejunal fold is attached closely to the duodenojejunal flexure or just below it. When this fold, which is *not constant,* crosses the flexure with a space between it and the bowel, we have formed the superior duodenojejunal fossa; and when no space separates it from the bowel no fossa exists; and we may then have this fold, if sufficiently developed, limiting the excursion of the bowel, acting as a potential point of obstruction. This fold generally contains an artery adding to its tensile strength.

Occasionally, even without the presence of a gastroenterostomy, we find at operation or necropsy the duodenum markedly dilated. While I was assisting the late E. H. Beckman of Rochester, an occasion was offered to explore a patient for indefinite gastric complaint, and the only abnormality found was a greatly dilated duodenum, equaling the stomach in size, and extending beyond the superior mesenteric artery to the flexure.

RELATIONSHIP OF STRUCTURES AND VESSELS AROUND THE FLEXURE

1. Lesser sac peritoneum
2. Coronary artery
3. Splenic vessels
4. Body of pancreas
5. Inferior mesenteric vein

ANTERIOR

1. Superior mesenteric artery
2. Celiac axis

RIGHT FLEXURE LEFT

1. Inferior mesenteric vein

POSTERIOR

1. Left renal vein
2. Nerve cords semilunar ganglion.
3. Inferior phrenic arteries
4. Aorta

Many writers attribute the dilated duodenum previous to or following operations to the compression of tense superior mesenteric vessels passing over it. It is difficult to imagine much tension on these vessels when we recall that they are attached to "floating organs," the contents of which have usually been cleaned out. In addition, the patient is lying down or is in a semirecumbent position, with the abdomen supported by dressings. Careful exploration will find the dilatation usually extending beyond these vessels.

In dividing this superior duodenojejunal fold it is necessary that one should be familiar with the anatomy in this region.

REPORT OF CASES

CASE 1.—A woman, aged 43, was operated on elsewhere by an excellent surgeon for duodenal ulcer. One week following the operation, persistent vomiting of bile and fluids started, which lasted, in spite of various conservative measures such as lavage, etc., until a second operation was performed three months later. A most interesting point was a negative roentgen-ray examination. The bismuth meal flowed freely into the efferent jejunum through the anastomosis, and the stomach emptied in less than two hours. At the second operation I found a perfect appearing anastomosis. It was soft and pliable, admitting the tips of three fingers. The lumen of the jejunum was not used up in the sewing. The opening from the anastomotic ring into the afferent and efferent jejunum seemed ample, and there was no kink at the proximal and distal edge of the new opening. There was no spur formation by mucous membrane. The afferent jejunum, the portion extending from the anastomosis to the duodenojejunal flexure, was a short loop of 2½ inches, not dilated, and it emerged from the mesocolon opposite the left border of the vertebral column and was attached to the posterior wall of the stomach from right to left (Mayo). The situation was puzzling, to say the least, as I had expected to find an obstruction. Further exploration displayed to the right of the vertebral column a greatly dilated duodenum, three times normal, extending on past the superior mesenteric artery to the duodenojejunal flexure. No superior duodenojejunal fossa existed here, which, when present, allows considerable mobility to this portion of the intestine. Division of this fold between two ligatures, as it almost always contains a vessel, relieved the obstruction. With the finger the duodenum higher up was partially freed from its attachment to the posterior abdominal wall. The enlarged opening was carefully attached to the jejunum in order to prevent a possible retroperitoneal hernia. The patient recovered.

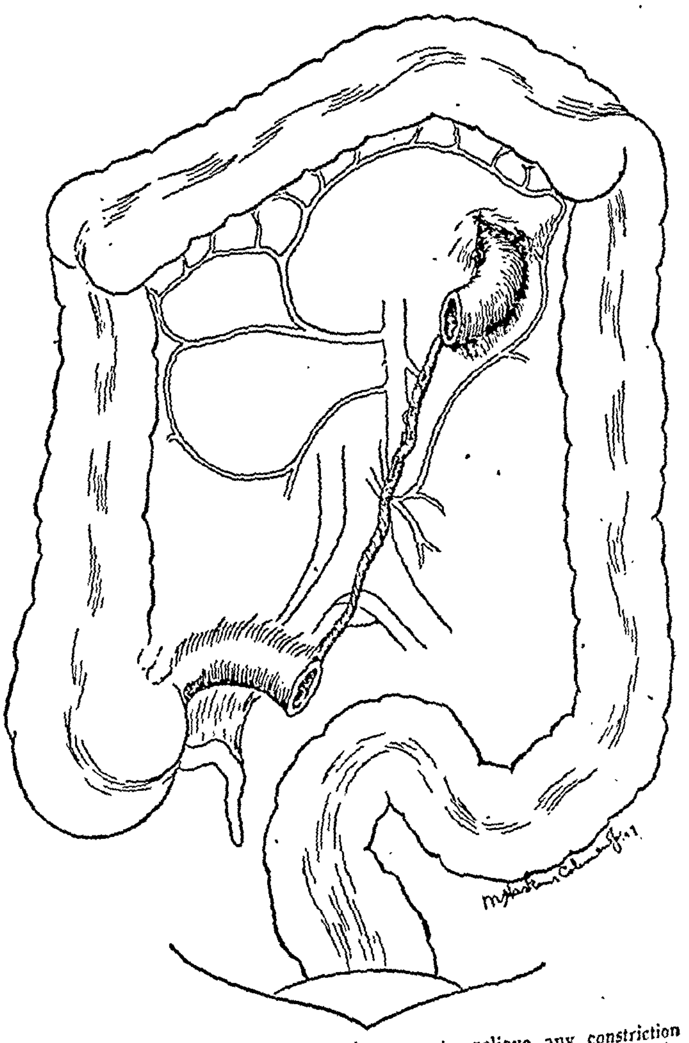

Fig. 4.—The fold cut between ligatures to relieve any constriction present. The manner of attaching the divided fold to the bowel in order to prevent a retroperitoneal hernia should be noted.

CASE 2.—On this patient, a man aged 56, I performed a gastrojejunostomy for duodenal ulcer three months previously. The roentgen ray in this case showed bismuth entering the efferent jejunum freely, as in the previous case. The emptying time of the stomach was not recorded. The jejunum in this case emerged from the mesocolon, just beneath the splenic flexure, so a left to right anastomosis was performed, and the jejunum was attached 1½ inches beyond the anastomosis, in order to prevent a kink, which was first suggested by Hadra in 1891. A fairly short loop resulted, preventing a sag in the jejunum. At the second operation, for persistent vomiting, the field of operation appeared normal. There were ample stomata at the anastomosis opening into the stomach, afferent and efferent jejunum, and no kinks or dilations were seen below the mesocolon. In this case the duodenum was tremendously dilated, being four times normal and most prominent to the right of the vertebral column. The dilatation extended up to the duodenojejunal flexure, which was moderately constricted by this crescent-shaped fold in the mesocolon, as was easily determined by the finger. In this case the jejunum had been drawn sharply to the right by its attachment to the stomach. The short loop proved to be too short, kinking a moderately fixed portion of the bowel, which contained a potential angulation. The finger was carefully inserted around the duodenojejunal flexure, gently dissecting it free, and this fold in the mesocolon was divided between ligatures. This patient died of peritonitis five weeks later, following a cholecystectomy.

COMMENT

These two cases were extremely interesting, and strongly emphasized three points: 1. The negative roentgen-ray examination, as the anastomosis worked perfectly. 2. The obstruction being caused by a too rigid opening in the mesocolon, and by structures close to it. 3. The point of exit of the jejunum in Case 2 and the direction of the anastomosis rendered necessary (left to right), in order to prevent angulation.

SUMMARY

1. A gastro-enterostomy is a mechanical affair, the chemistry of the alkaline duodenal contents playing a negative rôle.
2. It must assume a double function, draining constantly and freely the gastric and also the duodenal contents into the efferent jejunum.
3. A roentgen-ray examination may disclose the anastomosis working perfectly with marked symptoms of vomiting, etc., owing to the fact that the duodenum is obstructed by the dorsal border of the mesocolon.
4. The point of origin through the mesocolon is not constant, and the anastomosis should be made accordingly in the most convenient direction.
5. Occasionally the inferior border of the transverse mesocolon forms a distinct fold over the duodenojejunal flexure which, when attached to the bowel, may form a point of obstruction, even before and also after a gastro-enterostomy is performed.
6. If this fold at the time of operation is found to be developed sufficiently to constrict the bowel, it should be divided between ligatures.

Opium, Morphin and China.—In an address by Dr. Wu Lien Teh at the National Medical Congress in Canton, China, he said that the year 1917 would be made historic because of the banishment of opium, the curse of China for seventy-five years. The ten-year agreement between Great Britain and China regarding the importation of opium expired in March. Dr. Wu, however, gave warning of the alarming increase of the importation of morphin. In 1911 it is said from Great Britain alone came 5½ tons of morphin; in 1914, 14 tons, and the estimate for 1916 was over 16 tons. In the provinces of Manchuria and Shantung the ravages of the drug are dreadful, more than half of the "jail-birds" showing signs of the needle, and thousands of professional beggars and other poor people in the northern cities becoming victims and many dying in the winter months, not from cold, but from inability to work on account of the morphin habit. The practice, first introduced by emigrants from Swatow, is increasing rapidly. The drug is put up in small packages, sometimes with fancy names, such as white powder, soothing stuff, dreamland elixir, etc.

BLADDER DISTURBANCES DUE TO NERVE LESIONS *

GILBERT SMITH, M.D.
BOSTON

The occurrence of bladder disturbances as the early or predominant symptoms of certain rather unusual nerve lesions was called to my attention by two cases, one of syringomyelia and one of multiple sclerosis. Unless the possibility of such an etiology is borne in mind, the urologist may fail to find the reason for the persistence of certain abnormal conditions in the bladder.

Search through the literature of the past four years failed to reveal more than three papers on the subject written from the urologic point of view.[1] Caulk and Greditzer[2] call attention to the relaxation of the vesical sphincter in tabes dorsalis, dementia paralytica, tumor or gumma of the spinal cord, postapoplectic conditions, exophthalmic goiter, paralysis agitans, lead poisoning, and the continuous retention catheter.

Koll[3] and Greenberg[4] have both written about the diagnosis of nerve lesions by the use of the cystoscope, but nowhere in urologic writings have I found reference to the vesical aspects of certain diseases of the nervous system. Boxwell,[5] a neurologist, has published a brief but fairly comprehensive discussion of the subject, and mentions instances of vesical disturbance in cases of myelitis, alcoholic neuritis, hemiplegia and tabes. According to the neurologists, bladder disturbances are frequent and sometimes early accompaniments of various nerve conditions which are not mentioned by urologists. It would seem probable that some of these patients are seen first by the latter, and possibly, in the course of routine treatment, escape a correct diagnosis.

The exact relationship between disturbances of the bladder function and the pathology of nerve lesions is not always clear. In fact, the physiology of the normal act of urination is not absolutely definite. Langley and Anderson[6] have shown that the bladder in cats, dogs and rabbits receives motor fibers (1) from the second to fifth lumbar nerves, the fibers passing through the inferior mesenteric ganglion and reaching the bladder by way of the hypogastric nerves, and (2) from the second and third sacral spinal nerves, reaching the bladder by way of the nervi erigentes and the hypogastric plexus. The nerve fibers from the sacral cord seem to be more actively concerned in the reflex of urination; stimulation of the lumbar fibers sets up only gentle contractions of the bladder.

The classical work of Goltz[7] in 1874 established the general principles of the vesical reflex. He pointed out that gradual distention of the bladder induced gentle contractions. These expressed several drops of urine into the posterior urethra, causing thereby a sensory stimulation. This—the afferent part of the reflex—aroused the efferent impulse by which the bladder is made to contract vigorously and the sphincters to relax. Goltz showed that in dogs with spinal cord severed between dorsal and lumbar regions the reflex still existed, and that it persisted even when the lumbar cord was entirely destroyed. Thus it was established that the act of micturition is a reflex of a very primitive type, requiring not even a spinal center. The problem is complicated, however, by the fact that this reflex is very completely under the control of the will.

[3] Koll: Study of Twenty-Five Tabetic Bladders, Surg., Gynec. and Obst., 1915, **20**.

[4] Greenberg: Cystoscopy as a Diagnostic Aid in Spinal Disease, Med. Rec., New York, 1916, **90**, 634-636.

[5] Boxwell: Disordered Bladder Function, in Nervous Diseases, Tr. Roy. Acad. of Med., Ireland, 1914, **32**, 63.

[6] Langley and Anderson: Jour. Physiol., 1895, **19**, 71.

[7] Goltz: Arch. f. d. ges. Physiol., 1874, **8**, 478.

Before the bladder is anywhere near full, one can initiate the act of urination. By consciously relaxing certain perineal muscles and contracting others in the abdominal wall, one probably squeezes out the first few drops, which are sufficient to set the reflex in motion. The act then becomes automatic, unless, by a definite exertion of the will power, one closes the external sphincter and holds it shut until the contractions of the bladder have ceased. Conversely, when the bladder is overdistended, and urine squeezed into the posterior urethra sets in motion the reflex, the carrying out of the reflex can be prevented by an exercise of will power.

It is evident that the nerve mechanism of micturition is vulnerable at several points. If the roots of the sensory nerves are affected, as in tabes, the reflex arc is broken. If communication between the lower centers and the brain is interrupted, the act should theoretically become purely reflex and should be free from the inhibitive influence of the brain.

In general, disturbances of the bladder due to nerve lesions take one of several forms:

1. Those due to irritation of the sensory nerves, giving rise to frequency, urgency and hyperesthesia of the bladder neck. This occurs sometimes in tabes, in syringomyelia and in multiple sclerosis.
2. Retention, partial or complete, due to spasm of the external sphincter. Barney[8] explains this phenomenon in his careful work on tabes dorsalis. This condition occurs in other diseases besides tabes—in multiple sclerosis for example. It may be followed by dribbling from an overdistended bladder, but this is due primarily to retention.
3. True incontinence due to paralysis of the sphincters. This occurs in later tabes, in transverse myelitis of the lumbosacral region, and in syringomyelia.
4. Involuntary micturition. This may occur when the lower centers are cut off from the higher, as in trauma of the cord or in transverse myelitis, when these lesions are situated above the lumbar segments. The bladder will empty itself when the stimulus caused by increasing distention becomes sufficient.

Probably the most common disturbance of the bladder from the neurologic point of view is tabes dorsalis. This subject was worked up by Barney in 1910, and little can be added today to his thorough exposition. It would be unnecessary to take up the reader's time by a recapitulation of the well known course of that disease.

The only extraordinary cases which I found reported were those of tabes in children, described by Barkan.[9] He speaks of a girl of 9 years with tabes and nocturnal enuresis, and says that he has seen twelve cases of tabes in children within two years.

Another lesion of the spinal cord which may cause bladder disturbance is myelitis. If the lesion occurs in the lumbar cord, according to Gowers,[10] it will cause loss of vesical reflexes which results in dribbling without retention. If above that region, the reflex is first lost, and then becomes hyperactive. In other words, there is first retention, then involuntary voiding.

Trophic disturbances in myelitis may cause ulceration of the bladder.[10]

Syringomyelia is the occurrence of a glia-lined cavity in the gray matter of the cord. The symptoms are necessarily variable, depending on the location and size of the cavity. Jelliffe and White[11] speak of the loss of sexual desire and of testicle pains which occur. They refer to analgesia of the bladder and persistent priapism as occasional symptoms. In regard to bladder disturbances, they say that these "are not the rule, although at times appearing, usually late in the disease. When appearing early, they are apt to be transitory. They may be sensory or motor, irritative or paralytic. Cystitis is not infrequent in the later stages of the disease." With the dorsolumbar type of the disease, involvement of the bladder and rectum is not infrequent, while in the sacrolumbar type, it is usually present.

A patient with syringomyelia exhibiting marked bladder symptoms entered the Massachusetts General Hospital on the genito-urinary service in October, 1916. The relation between the vesical disturbances and the nerve lesion was not perfectly clear, yet we were unable to account for the former in any other way. The patient was a woman of 30, a domestic who had had three illegitimate children. Two of them were born dead; the last one, which lived, was born five years before. The patient complained of painful, burning micturition of eight weeks' duration. Urination was followed by dribbling, tenesmus, and a desire to urinate again. The urine contained pus and colon bacilli. Cystoscopy was done under spinal anesthesia. Considerable trabeculation of the bladder wall with a distention of 6 ounces was noted. Both ureters were catheterized; a small amount of pus and a growth of colon bacilli were obtained from each. Roentgenoscopy and the Wassermann test were negative. The peculiar thing was that during her twelve days in the hospital, the patient continued to have constant severe spasms of the bladder, in spite of every kind of local treatment. Also, she had, on several separate observations, a residuum of 6 ounces.

She was seen in consultation by Drs. Taylor and Paul, who made the diagnosis of *syringomyelia*, because of atrophy of the small muscles of the hands and various sensory disturbances.

Multiple sclerosis, or disseminated sclerosis, is characterized by the occurrence of small patches of sclerosis in the spinal cord, or brain, or both. These patches are due to the degeneration of the included nerve tissue, which is later replaced by neuroglia. Their size varies from that of a pea to that of a walnut, and they involve the white matter primarily. Sometimes the nerve roots are affected as well.

The etiology of this condition is unknown. It occurs most often between the ages of 25 and 35 years, and although naturally the symptoms vary according to the location of the patches, the most usual symptoms are loss of muscular power in the limbs, a jerky incoordination, nystagmus, and staccato utterance. The individual is prone to outbreaks of emotion, manifested either by laughter or by tears. Babinski's sign is always present; the absence of abdominal and epigastric reflexes is a valuable point in the diagnosis (Gowers[12]).

[11] Jelliffe and White: Diseases of the Nervous System, 1915, p. 355.

The importance of this disease to the urologist is suggested by the words of Collins and Baehr.[13]

> Frequently there is associated a weakness of the bladder; there is inability to hold the urine as well as usual, and there may be urinary incontinence at times. . . . Urgency is an early symptom, and is due to hypertonicity of the bladder muscle. Intense spasms of the sphincter may occur, causing retention; later in the disease, incontinence is present practically always.

Sixty-five per cent. of Collins and Baehr's cases were of the spastic type, usually accompanied by bladder disturbances. Jelliffe and White[14] say that the bladder is involved in from 75 to 80 per cent. of all cases. "The patient feels a sense of insufficiency, and has to strain to pass water. Complete paresis with incontinence is rare." The many ups and downs in the bladder symptoms are remarkable. The disease is progressive, with intervals of improvement, but care of the bladder as in tabes would seem to be indicated.

The bladder manifestations of multiple sclerosis described by these authors were reproduced with striking accuracy in the following case:

M. C., a nurse, aged 28, was seen about one year ago. Four years before, while in training, she became "run down" and very nervous. Previously, she had always been well, except for measles. Accompanying her breakdown were bladder symptoms—great frequency and inability to hold the water. Association with insane persons led her to fear that she might have some nervous disease, so she went to the Massachusetts General Hospital and had an examination of the spinal fluid. This was normal. She returned to work and has remained at it, in spite of a sense of weakness in the legs, and what she characterized as a "weakness of the bladder." At times she wet the bed at night.

She was a rather pale, tired looking girl. The pupils reacted normally. There was no Romberg; the knee jerks were normal; general examination was negative; the kidneys were not palpable; the pelvic organs were normal. The urine by catheter was hazy, revealing no sugar nor albumin. A centrifuged sediment showed some pus cells, a few red blood cells, and vast quantities of staphylococci. No tubercle bacilli were found. Roentgenoscopy was negative for stone.

The bladder contained 4 ounces of residual urine, with distention of 8 ounces; the bladder wall showed a fine trabeculation; the mucous membrane was clean. The ureteral orifices were normal. Both ureters were catheterized with a flow of normal urine.

Not being awake to the diagnosis, and finding the urethra abnormally red and granular, I treated her with urethral applications, sandalwood oil and bladder lavage. The residual urine remained about 4 ounces throughout July, August and September. In November, I noted that her chief trouble was fatigue in the front of the legs. The bladder symptoms improved a very little, the greatest improvement following rest from work, bromids and belladonna.

The patient was very emotional, laughing one moment, crying the next. On December 22, the residuum was only 1½ ounces. In December, I sent her to Dr. George Clymer for neurologic examination. He reported that he found a positive Babinski, negative abdominal and epigastric reflexes, and positive ankle clonus—in short, that she unquestionably had multiple sclerosis.

He started treatment with solution of potassium arsenite (Fowler's solution) and the application of electricity over the bladder. Whether or not as a result of this treatment, the patient showed remarkable improvement. The residuum cleared up, the urine became normal, and for two months she wet the bed only during menstruation. She has had a slight remission, but generally speaking is much better, and has started to work again.

I have reported this case at some length because it is a striking example of the vesical manifestations of multiple sclerosis. Bladder trouble was practically her only complaint, yet there was the definite background of a nervous disease which escaped detection on routine physical examination.

The presence of residual urine should have suggested at once the necessity of a more thorough nerve examination.

Syphilis of the brain and cord, whether of the diffuse type or circumscribed, as in gumma, may produce disturbances of the bladder, varying with the location and extent of the lesion.

Tuberculous meningitis may do likewise. Pearson,[15] in 1902, and Moody[16] in 1916, called attention to the fact that retention of urine coming on in a person with tuberculosis is an early symptom of an invasion of the meninges. Moody quotes four cases, all proved by necropsy, in support of this theory.

Neuritis of alcoholic origin (Boxwell) may produce incontinence, and that postdiphtheritic neuritis can result in retention, the following case will show:

In 1909, J. K. (162960), aged 62, a laborer, was sent into the Massachusetts General Hospital from the outpatient department because he was found to have a residuum of 30 ounces. His only previous illness had been diphtheria twenty years before. At that time he had stoppage of water, and had had dribbling of urine, with pain at the beginning of urination, and he has had difficulty in starting the stream ever since. There was slight frequency at night. The reflexes were normal. The patient's general physical condition was negative except for some cardiac hypertrophy. The prostate was not enlarged nor tender. The catheter passed easily and drained 30 ounces of foul urine. He was seen by the consulting neurologists, who found evidence of nerve lesions. A cystoscopy was done by Dr. Lincoln Davis, who found nothing obstructive, and thought the bladder condition due to his diphtheria. Epididymitis set in, then pericarditis. He died, and at necropsy, the kidneys showed suppurative nephritis, the ureters and pelves were dilated, the bladder showed a thickening of the walls with fibrous induration in the region of the outer coat and much hypertrophy of the trabeculae. Between the hypertrophied trabeculae in several places, there were smooth walled diverticula, the largest being about 3 cm. in the greatest dimension. The prostate showed very slight, if any, enlargement of the lateral lobes. There was a very small eminence in the situation of the median lobe. The prostatic urethra was free and somewhat dilated.

That various forms of insanity are accompanied by disturbances of the vesical and rectal sphincter is, of course, well known; the bladder disturbances are usually late symptoms.

Not so much in them as in the field of organic nervous diseases, such as multiple sclerosis, syringomyelia and tabes, is cooperation between urologist and neurologist most necessary. The most troublesome symptom of those conditions may be vesical, and the first assistance sought by the patient may be from the urologist. It is well for the latter to have in mind the fact that a nerve lesion may be the cause of marked hyperesthesia of the bladder, characterized by great frequency, or of unexplained residual urine in cases without urethral obstruction.

ABSTRACT OF DISCUSSION

Dr. W. C. Quinby, Boston: I think it would be of value to place along side of Dr. Smith's results those of a rather hasty investigation of cases occurring in the last four years at the Brigham Hospital in Boston, in the service of Dr. Cushing, which showed definite bladder lesions and bladder symptomatology due to various known lesions of the cord. The bladder symptoms following these various spinal cord lesions depend entirely on the location and nature of the lesion; therefore we find the greatest difference in the symptoms, as has already been pointed out by Dr. Smith. In going over the cases at the Brigham I have chosen twenty which showed definite symptomatology in the bladder. These were as follows: 1 case of transverse myelitis; 3 cases of spinal cord endothelioma; 1 case of spinal cord angioma; 1 case of metastatic sarcoma; 1 bullet wound of the cord; 12 cases of fracture of the spine; 1 case of hematomyelia without fracture of the spine.

I wish to call attention merely to the broad deductions and conclusions which one can draw from a study of these cases, without going into the details at this time.

A lesion at the proper level to cause a complete paraplegia always involves the bladder, causing a paralysis of the detrusor, with resulting retention of urine. Following this, at a later or earlier period according to the severity of the injury, there supervenes incontinence with overflow; then, later on, if the patient lives and the condition persists, true incontinence, with a greater or less degree of residual urine, is usually seen. Sooner or later infection always occurs. Sometimes it occurs with startling severity, with symptoms and signs of infection of the kidney and bladder of greater intensity than those signs from the spinal lesion, and death ensues. In other cases, however, the infection may be partly resisted by the patient, and fairly often cases occur showing a chronic cystitis and pyelitis from time to time, increasing in intensity and causing symptoms of general sepsis.

Dr. Bransford Lewis, St. Louis: There is one phase of the subject of involvement of the mechanism of urination that is interesting rather more from the urologic standpoint, and I read a paper on the subject before the American Urological Association about three years ago, under the title of "Studies in Obscure Forms of Prostatic Obstruction and Vesical Atony" (Ann. Surg., March, 1915). During the last ten years or so there have appeared from time to time discussions of prostatic obstruction by very able men, like Thomson Walker of England, Albarran and others, and Germans of equal prominence, in which they spoke of cases of prostatic obstruction with what they termed unrecognizable causation. They, to their own satisfaction, excluded nervous origin and let it go at that—apparently what we used to term idiopathic, whatever that means. I discussed the subject and adduced a number of cases, and from my standpoint I could not believe there was such a thing as a retention of urine, atony and all those sequelae, without causation, and in the study of obscure forms of prostatic obstruction mentioned I declared they were due to certain physical conditions that were not recognizable according to the methods employed for diagnosis; such, for instance, as a moderate degree of contracture of the vesical neck that was not recognizable by the various methods of instrumentation, either endoscopic or cystoscopic, until one got one's finger right there and felt the contracture that until then was not recognizable.

Another form of obstruction that ought to be given more consideration, I said, was that of syphilitic influences through the spine, producing interference with the evacuation of the bladder without there being an evident tabes or any lesion that was apparent excepting on the most careful analytic study of the case. And that applied to younger individuals as well as to the old ones, and also to inherited syphilis. I spoke of one patient who had been subject to numerous surgical operations; he had had five major operations done on him, and he was only about 18 or 20 years of age when I saw him, and he had never been able to urinate with any degree of satisfaction. He had never acquired syphilis, but he did have inherited syphilis that had bestowed on him this stigma that had required all his attention all of his life. It was proved by the Wassermann and other tests, and he improved under the influence of antisyphilitic treatment.

Dr. John T. Geraghty, Baltimore: In connection with Dr. Smith's paper and Dr. Lewis' discussion, I would disagree with Dr. Lewis. I was much astonished a few years ago to find some cases of obstruction to urination for which we could find no cause. We supposed, of course, that they were probably unrecognized cases of contracture of the vesical neck. Operation to divide the vesical neck, however, gave no relief. We have had now a series of six cases of that type in which all of the clinical findings were simply those found with a spinal cord lesion; sometimes dilatation of the vesical orifice, residual urine as a rule, and all of the classical symptoms that go with the spinal cord cases that Dr. Smith has mentioned. Two of these cases have come to necropsy, and we were able to obtain a most complete necropsy, including the central nervous system, and the most careful studies of the central nervous system, and the bladder and the urinary apparatus failed to show the slightest cause for the obstruction. There is only one explanation which I can think of which will account for these cases, and that is that we will probably have to admit the possibility of a peripheral lesion; that it is possible to have a peripheral neuritis which will affect the bladder. That is hard to understand, because if there is a degeneration of the peripheral nerves, sooner or later there should be evidences of that in the spinal cord. In these cases there was nothing in the spinal cord to indicate that the nerves had been injured. Furthermore, these two patients, instead of having atrophied bladders, had hypertrophied bladders. In each instance the vesical orifice was dilated; there was no valve formation, no diaphragm.

Dr. C. M. Harpster, Toledo, Ohio: The idea that trabeculation is one of the earliest premonitory symptoms in tabes I think is not absolutely substantiated. I should like to call attention to a very unique case the study of which it was my pleasure to take part in. This was of a man who had a fracture of the fifth and sixth cervical vertebrae. If I remember my anatomy correctly, the brachial plexus is made up of the four lower cervical and first dorsal nerves.

I was especially interested in studying the effect of this injury of the spine on his bladder phenomena. We studied this patient for about six months, and we could put him to sleep, make him cease talking and paralyze him from the neck down at will. That is, we had him in a plaster helmet and when that was removed he would immediately lapse into a paralysis of speech, a paralysis of one or both limbs and of the bladder and rectum. I repeatedly induced these phenomena; that is, when the cast was removed or replaced for investigation this patient had an incontinence of his urine. We had to catheterize him. He always had an incontinence, which was always relieved on the replacement of the cast. By making traction on his neck and chin, even if he could not speak to us, he immediately would begin to talk and move his arm, and on the removal of the pressure of the fragments of bone on the cord he could move his limbs and void his urine.

Dr. Leo Buerger, New York: I readily appreciate that the phenomena of urination are developing into an understandable quantity. If I understood Dr. Smith correctly he said that injuries to the spinal cord above the lumbar region seemingly had no effect on urination. Dr. Quinby said that a fracture of the spine had caused incontinence and other phenomena. Now, the bladder is developed from the rectum; it is a part of the same tissue. If that be true about this etiologic factor neurologically that the spinal cord does not necessarily control urination, it would bring it down to the view that it must be either due to the sympathetic or to the vasoconstrictors or the vasodilators—the vasomotor system. This becomes very interesting, because from the vasomotor system we might have any sort of a condition producing urinary symptomatology.

I had a man who had not been able to pass his urine and every sort of an examination had been made on him. He was a man of importance in his neighborhood. He could not urinate, and there was no known reason. He was the father of healthy children. He was a very healthy appearing man and came from healthy antecedents. I played with him for about six months. At the end of that time he was riding one day in his automobile, the chauffeur was intoxicated, there was an accident in which the patient's back was injured, and he has been able to urinate ever since.

Dr. Martin Krotoszyner, San Francisco: In every otherwise not explainable bladder lesion of functional character the urologist always must be on the lookout for the possibility of an underlying etiologic factor in the cerebrospinal center, the insidious onset of which may first manifest itself by bladder symptoms. A great many of these conditions are either diagnosed too late for adequate specific treatment, or, especially when occurring in men of the age of prostatism, are diagnosed and treated as lesions due to mechanical obstruction. The solution of that problem, to my mind, does not depend so much on competent neurologic counsel, which often is obtained when nerve centers are irreparably damaged, but rather lies in the acquisition on the part of the urologist of a better knowledge of neurologic diagnostic methods as the only means of establishing an early diagnosis.

Dr. William F. Braasch, Rochester, Minn.: The value of cystoscopic data in the early diagnosis of neurologic conditions is not generally appreciated among neurologists. The cooperation of the urologist and the neurologist is often very necessary. Whenever there is any doubt as to whether or not a patient has a central nerve lesion he should be referred to a competent urologist for cystoscopic data. In a high percentage of the cases such data are of great practical value to the neurologist. The well-known changes in the bladder following cord lesions are of two types, namely, trabeculation and dilatation of the internal sphincter. The dilatation of the internal sphincter takes place, in the majority of cases, in the later stages of nerve lesions. The first change is trabeculation, which, as you know, with a cord lesion is quite typical of a large percentage of cases. The trabeculae appear ridge-like and are confined largely to the upper portion of the bladder. Without any nerve lesion, however, patients are frequently seen with irritable bladders which on cystoscopic examination appear trabeculated similarly to nerve lesions. We cannot always, therefore, depend on the cystoscopic picture, particularly in the early stages of nerve lesion.

Dr. Edward L. Keyes, Jr., New York: One diagnostic point has been of so much value to me that I venture to bring it to the attention of this assembly. I have in only one case known a tabetic with bladder paralysis to show active ankle jerks, though a number of patients have shown normal knee jerks. Therefore, it seems wise to examine all of our prostatics for ankle jerk. There are cases in which we cannot elicit the ankle jerk and in which there is no cord lesion; nevertheless the absence of the ankle jerk will frequently put us on the right track. In one instance I remember particularly, while the neurologist was in the ward examining the man a laboratory report on the spinal fluid came in. The neurologist said that although the patient had absent ankle jerks and had loss of deep muscle sense in his calves, nevertheless he had no spine lesion. Whereupon the report was read showing characteristic tabetic changes in the spinal fluid.

Dr. Charles W. Bethune, Buffalo: There is another sign which I have frequently observed in tabetic bladders; that is, a gaping of the ureter due to paralysis. Sometimes if one can turn the cystoscope in the right direction one can see a quarter to half an inch up the ureter. If a ureter catheter is introduced through the cystoscope in tabes the patient is unable to feel contact at any point within the bladder.

Dr. Winfield Ayers, New York: I believe we can make one of the earliest diagnoses of beginning tabes in any form by examining the bladder. I recall the last case that came under my observation. The patient had been under a first-class man in New York, who had been treating him with bladder lavage for about a year. On my first observation I immediately asked him if he had had syphilis. He said he had. I tested him for the lesions commonly shown as tabetic, for instance, the pupil, knee jerk, etc. The pupil reacted perfectly, the knee jerk was increased, the ankle jerk was increased. I had a Wassermann made and it was four plus. The only symptom the patient had was a twitching. In washing his bladder his legs would twitch. I put him on a course of sodium cacodylate and all of his bladder symptoms disappeared. His jerk has not disappeared, but he is beginning to have a loss of contraction of the pupils to light, and that seems to me to indicate that he came to me in the pretabetic stage. I think that by seeing these patients early, recognizing them at once from the bladder, the possibly severer effects of tabes may be blocked off. I have not had so much experience in the other forms, but in the cases of fracture of the spine that I have seen, in almost every instance they followed out the symptoms described here.

Dr. G. G. Smith, Boston: The record in the paper of nerve lesions is very incomplete, I realize, and yet I felt from my comparatively slight study of the situation that I had learned several valuable lessons. There are a number of nervous diseases causing bladder symptoms which must be diagnosed by a consideration of something more in a patient's condition than the mere examination of knee jerks, pupils and Romberg. Unless one is quite familiar with the symptomatology of some of these nervous diseases, one is likely to overlook them. There is no reason why the urologist should not know these things, but most of us do not. I know I was entirely ignorant of the symptoms of multiple sclerosis, and I had to look up the description of syringomyelia before I knew what that was.

I think the diagnosis of nerve lesions with the cystoscope is difficult, because, as Dr. Braasch pointed out, the bladder manifestations are necessarily limited; we have practically only three things: first, hyperesthesia; second, retention; third, relaxation of the sphincter, with perhaps dribbling. Dribbling may be caused by any one of a number of different nerve lesions, and these different nerve lesions are not always easy to reconcile with the pathology of the disease.

Dr. Geraghty spoke of unexplained bladder disturbances and said that they might be caused by a peripheral neuritis. I would simply say in connection with that that I did have one such case, one of postdiphtheritic paralysis, in which a postmortem examination of the spinal cord was not made, but in which apparently a peripheral neuritis limited to the bladder was the thing that was causing the symptoms.

In regard to Dr. Buerger's remark that I had said injuries above the lumbar cord did not cause symptoms, I think he did not quite understand what I said. I said that injuries of the cord above the lumbar region would allow the reflex to go on, but if the lower centers were cut off from the brain the patient would not be able to stop the act of urination. It is a fact, however, that complete section of the cord is followed by retention of urine at first, although theoretically it should have no effect on the act of urination.

Work of Rockefeller Foundation in China.—The China Medical Board of the Rockefeller Foundation has made its annual report describing the preliminary steps which have been taken in Chinese cities to "promote the development of a comprehensive and efficient system of medicine in China." The main plan of the board is to establish in Peking and Shanghai medical schools which shall be of the same grade as the better medical schools of this country, but the creation of these institutions has been delayed by the failure of Chinese schools to turn out students sufficiently well grounded in science and general education to take advantage of these courses in medicine. Hence, the first step has been to open in Peking a premedical school. The board has granted $150,000 to the Tsinafu Union Medical College, which has been cooperating in furnishing the necessary preliminary training to Chinese students. Until the medical school is built by the China Medical Board its work will be carried on by the school and laboratories of the Chinese Red Cross Society. This plant was operated by the Harvard Medical School of China until July, 1916, when it was taken over by the Rockefeller Foundation. While preparing for the founding of these two medical colleges, the foundation extends medical help through various missionary societies.

DIARRHEAS ACCOMPANYING GASTRIC ACHYLIA*

MARTIN E. REHFUSS, M.D.
PHILADELPHIA

In the study of the diarrheas accompanying gastric achylia, it is essential that we have a rational conception of that condition. It is my intention in this paper to consider first some studies which we have carried out on achylia and then to follow it by our observations on the form of diarrhea accompanying that condition. In a former contribution, I pointed out the fact that by means of fractional analysis, it was possible to throw considerable light on certain phases of achylia and to make two broad distinctions, namely, a differentiation between true and false, or spurious, achylia, the former being a condition which persists throughout the entire stage of gastric digestion, the latter being simply a form of delayed gastric secretion, since after a period of one hour and a half there is to be found a perceptible secretion. If this method had been employed in previous studies of this subject, the number of true achylias recorded would be very much less. This does not alter the fact, however, that these spurious forms of achylia are likewise accompanied by diarrhea in a certain proportion of cases. The second distinction which was brought out in that paper was the differentiation between psychic achylia embracing a suppression of the first stage, and a chemical suppression which for the want of a better name we called chemical achylia. These are both spurious or false achylias, since there is not a total suppression of secretion.

I wish to present some cases illustrating different phases in the mechanism of achylia. I am aware that gastric achylia is associated with many toxic, infectious, nervous and vascular disturbances, but I have attempted in the limited number that I have been able to study to definitely attach a cause, the removal of which resulted in a disappearance of the gastric condition. The following cases to my mind represent at least a close association of the disappearance of a causative agent with the clearing up of a gastric condition. Apparently, it can come from fright or nerve inhibition (Case 1, student), through severe blood dyscrasias (Case Wa), through direct infection in the gastric wall (Cases Si, Ka, Du, H., K., D., T.), through a ductless gland disturbance (Case K.), besides the chronic forms of inflammation of the stomach (Cases Hi., and Mrs. H.). At least in the cases cited there is an association between improvement in the gastric condition and a disappearance of the cause.

The studies that have been carried on in the department of physiologic chemistry under the direction of Drs. Hawk, Bergeim, Fishback, Fowler, Smith and myself seem to indicate that there are many important points regarding the human gastric secretion that have not been sufficiently emphasized. In the first place, in a series of studies on the psychic secretion in normal untraumatized persons, we were able to demonstrate a very pronounced psychic secretion lasting from sixty to eighty minutes (from 105 to 274 c.c., averaging 122 T. A.; from 74 to 114.5 c.c., averaging 97.3). Atropin reduced this secretion approximately two thirds as to both its quantity and its acidity, showing that even during this secretion there is probably initiated a chemical mechanism uncontrolled by atropin. On the other hand, there are persons in whom this secretion does not occur, and in a large series of persons subjected to several thousand fractional analyses (Carlson, Schmidt and others) in order to ascertain the action of the various foodstuffs in the stomach, we came across several perfectly healthy persons who presented a total and persistent gastric achylia.

On one of these persons we made a series of studies. This person was found to have a persistent achylia regardless of the type of food administered. An Ewald meal, toast, beef, beef extract with salt and pepper, were all incapable of inducing any acidity or any peptic activity. We therefore gave this person dilute hydrochloric acid on one occasion and sodium bicarbonate on another occasion. In both instances, although the substances were markedly different, the person poured out, or rather secreted, a fluid that served as a diluting agent, but possessed apparently none of the ordinary characteristics of the gastric secretion. In other words, it is probable that, even in achylia, there is poured out a secretion that, while not acid and not containing pepsinogen or renninogen, nevertheless might be capable of activating the intestinal secretion. Whether this occurs in pathologic cases, I cannot say, but we feel that our ordinary chemical methods did not develop the possibilities in this secretion. Experimentally, we found that it was possible to produce a marked delay in the appearance of the secretion by means of concentrated solutions of glucose and salt. Furthermore, it is possible by intermittent neutralization and feeding to produce a total anachlorhydria over long periods of time, as we learned from studies that we made in connection with ulcer treatment.

All these observations bring us down to the diarrheas accompanying achylia. In considering this subject we must realize these important points: 1. Approximately only 30 per cent. of patients with achylia present diarrhea, for many in my experience show constipation, and a large percentage show merely a tendency toward looseness of the bowels on slight provocation. 2. The incidence of diarrhea is almost as great in subacidities. 3. There can be no question that a simple total achylia alone is by no means followed by diarrhea. In the foregoing studies none of the experimentally induced delays were followed by looseness of the bowels, and in the instances observed among normal persons there was no diarrhea. We must therefore look not in the stomach, but elsewhere for an explanation of this phenomenon. The points which impress me in gastrogenous diarrhea are:

1. The apparently acute onset in many of the cases, ushered in frequently by signs of infection, not infrequently by some systemic disturbances.

2. The intermittence in the appearance of the symptoms. Many of these cases showed a marked intermission punctuated by simultaneous disturbances elsewhere.

3. The frequent association of evidence of inflammatory condition of the small bowel rather than simply exaggerated peristalsis as revealed by fecal study.

We have been told that the causative factors in gastrogenous diarrhea are: (1) gastric hypermotility resulting in too rapid evacuation of insufficiently digested material from the stomach, which results in (*a*) irritation and exalted small intestinal peristalsis, and (*b*) even inflammation of the intestine or infection; (2) the association of a similar disturbance in the secretions of other organs, such as the pancreas, and (3) a removal of inhibition of fermentative changes in the bowel (normally controlled by gastric hydrochloric acid) resulting in a form of fermentative catarrh of the bowel.

I have attempted to study, from all these angles, those cases in which there was looseness of the bowels or diarrhea, and it seems to me that the following statements are justifiable: It is hardly likely, with the exception of profoundly heightened nerve irritability, that increased gastric peristalsis is alone responsible for the appearance of diarrhea, since I have frequently injected improperly digested material into the duodenum through the duodenal tube without inducing looseness of the bowels. I have even injected irritants such as silver nitrate and iodin into the duodenum without inducing diarrhea. It is my belief that any acceleration of gastric peristalsis induced simply by rapid evacuation is lost in the small bowel and has little to do with, or at least does not control, the movements of the colon. Irritating material as long as it remains irritating might, however, induce hyperperistalsis, but even partially digested or undigested fibrin or connective tissue, when introduced into the small bowel, is incapable of producing this effect. In other words, intestinal compensation is the normal safeguard, and must be considered in any explanation for regular or even delayed bowel action in over half the cases of achylia. On the other hand, ruptured intestinal compensation, either through a primary weakness in the intestinal mechanism or a secondarily induced inflammation or infection, is, I believe, in most instances responsible for gastrogenous diarrhea.

I have been on the lookout for these cases for a long time, and in practically each case of unquestioned achylia in which there was looseness of the bowels, or even fifteen to twenty movements a day, there was associated with the condition certain other factors which more or less explain the condition. For instance, psychic disturbances were nearly always responsible for diarrhea (Potter's). On several occasions one patient had protracted periods associated, or rather ushered in, with signs of intestinal infection. In other cases (Simpson, Hirsch and Kane) the diarrhea came at intervals, nearly always associated with an unquestioned enteritis, an achylous gastro-enteritis. Mr. H. practically always developed diarrhea after the eating of certain kinds of food, particularly fish. Whether this was anaphylactic or not, I am not prepared to state. On four separate occasions covering a duration of several months, he was found to have a most persistent achylia. On three occasions he developed a diarrhea. At one time there were signs of cholecystitis, at another time unquestioned angiocholitis with slight jaundice, and in all cases there was a general enteritis. The connective tissue lientery, alone supposedly characteristic of achylia, is to my way of thinking rare. Nearly always the fecal formula will include evidences of small bowel infection, intimately mixed mucus, not infrequently biliverdin, and often poor fat digestion and deficient cellulose consumption. But rarely are there associated signs of pancreatic disturbance. In only one case could I find the two associated, and in that case duodenal intubation revealed a secretion simply giving the reactions for amylase, while the fecal studies showed deficiency in the digestion of all the foodstuffs. This patient, however, had chronic diffuse nephritis, and has since showed improvement in her gastric secretion as well as her ability to handle food. The diarrhea in gastric achylia may be of four types:

1. The first type comprises simply loose pasty movements containing little or no mucus, but undigested meat and connective tissue. Meat fibers are in clumps, but partially digested fibers are seen.
2. The second type is marked by watery movements with the above morphology and undigested cellulose; bile is converted; fats split are often unabsorbed.
3. The third type consists of either of the foregoing with excessive mucus. The mucus may contain excessive leukocytes or not.
4. The fourth, a greasy type, comprises two forms, one greasy, consisting of split fats and connective tissue and meat fibers, and a second in which an enormous amount of neutral fats predominate over normal often undigested starches.

7	10:29	2	Tr. down f. f. liq. clear, colorless	7.0	...	3.0
Lav.	.....	88	No sol. clear, colorless	2.0		

The first and second are the so-called typical types of achylous diarrhea, the second being due to the excessive irritability of the undigested food. Type 3 is the type usually seen with putrefaction in infected gastritis, in gastric carcinoma, and in the gastro-intestinal catarrhs. Type 4 in both forms is seen with the association of the biliary and pancreatic syndrome.

The difficult point for me to establish is, just how far the diarrheas are due simply to secretory loss and how far to infection and to irritation. Only in a certain proportion of cases do small doses of dilute hydrochloric acid correct the condition. In Type 4, hydrochloric acid is without effect, and the substitution of a fat-free or a low fat diet removing irritating fatty acids produces much better results. In Type 3 hydrochloric acid is without effect, in many instances, while in clean-cut cases of Types 1 and 2 it often works magically, but not so magically as I have been lead to believe.
